: COUNCIL ON PHARMACY AND CHEMISTRY, PRESENT AND FUTURE *

W. A. PUCKNER, PHAR.D.
Secretary, Council on Pharmacy and Chemistry
CHICAGO

:e world war marked an epoch in the existence of Council on Pharmacy and Chemistry as it did in luman endeavors. The information and experi- which had been accumulated by the Council ng its thirteen years' existence was drawn on by our rnment, directly or indirectly, and it also received ideration in England, France,[2] Belgium, Holland,[3] Sweden and elsewhere. In the world wide justment that has begun, the efforts of the Council, and present, will influence the plans of those who ge in the manufacture or sale of medicines, and, oubtedly, will be the incentive to the establishment imilar bodies in other countries.

s secretary of the Council almost from the time of rganization in 1905,[4] and knowing the work of its ibers and its collaborators, I am firmly convinced this body has deserved the endorsement and sup- given it by the American medical profession. I come this opportunity to present an outline of the ncil's past activities and to speak of some of the problems of the future, because I feel assured that a knowledge of its endeavor to improve drug therapy will increase the profession's confidence in the Council and add to the number of its supporters.

THE COUNCIL'S ACTIVITIES

Organized primarily for the purpose of putting a stop to false declarations with regard to the composition of proprietary medicines, the Council's activities have broadened until its work may be characterized as "a propaganda for the rational use of drugs." The following are some of its activities:

1. *New and Nonofficial Remedies.*—This is an annual volume, issued by the Council. It describes both proprietary and unofficial nonproprietary drugs which are deemed worthy of consideration by the medical profession. To be admitted to this book, a preparation must comply with certain definite rules which stipulate, in effect, that its composition be declared, that no untrue or grossly exaggerated claims be made for it, and that it shall give promise of having therapeutic value.

With the exception of a few which are still under consideration, the Council has considered all proprietaries whose owners or accredited agents have requested that an examination of the products be made, and it has admitted to the book those which were found eligible. In addition, the Council has examined all of the more important or widely exploited proprietaries, even when no examination was requested, and it has admitted those of this group which were found eligible. Further, the Council has admitted to the book certain unofficial, nonproprietary articles which seemed to give promise of therapeutic usefulness, and it has established standards for the control of their identity and purity, and listed those brands which complied with these standards.

As most proprietary medicines are of a more or less experimental nature, they are accepted for inclusion in New and Nonofficial Remedies only for a limited time—usually a period of three years. At the expiration of the period of acceptance, each preparation is reexamined and retained only if the claims made for it and the present day knowledge of its value permit this action.

Since manufacturers give information only in regard to their own products, New and Nonofficial Remedies groups together articles of a similar character, and includes in each case a general discussion of the group for the purpose of comparison, not only with each other, but also with the established or pharmacopeial drugs which members of the group are intended to supplant.

In brief, New and Nonofficial Remedies is a book in which are described preparations that have been

Although the Council on Pharmacy and Chemistry was estab- in 1905, it is likely that only a small percentage of physicians just what the Council is, or have any conception as to its personnel its ability to judge the available evidence for proprietary medica- The personnel has changed from time to time since 1905. At nt its membership is: C. L. Alsberg, A.M., M.D., chief of the u of Chemistry, U. S. Department of Agriculture, Washington, ; R. A. Hatcher, Ph.G., M.D., professor of pharmacology, Cornell ersity Medical College, New York City; A. W. Hewlett, M.D., ssor of medicine, Leland Stanford Junior University Medical ol, San Francisco; John Howland, M.D., professor of pediatrics, s Hopkins University Department of Medicine, Baltimore; Reid , M.D., professor of pharmacology, Harvard University Medical ol, Boston; Henry Kraemer, Ph.D., professor of pharmacognosy, ersity of Michigan College of Pharmacy, Ann Arbor, Mich.; W. T. ope, A.B., M.D., Bard Professor of the Practice of Medicine, ge of Physicians and Surgeons of Columbia University, New York ; G. W. McCoy, M.D., director of the Hygienic Laboratory, United s Public Health Service, Washington, D. C.; Lafayette B. Mendel, , Sc.D., professor of physiologic chemistry, Sheffield Scientific ol, Yale University, New Haven, Conn.; F. G. Novy, M.D., professor of bacteriology, University of Michigan, Ann Arbor, ; W. W. Palmer, B.S., M.D., associate professor of medicine, ge of Physicians and Surgeons of Columbia University, New York ; L. G. Rowntree, M.D., professor of medicine, University of esota Medical School, Minneapolis; Torald Sollmann, M.D., pro- r of pharmacology and materia medica, Medical Department, Western Reserve University, Cleveland; Julius Stieglitz, Ph.D., Sc.D., .D., vice chairman of the Council, professor of chemistry, University of Chicago, Chicago; G. H. Simmons, M.D., LL.D., chairman of the ncil, editor of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, Chicago, and W. A. Puckner, Phar.D., secretary of the Council, tor of the Chemical Laboratory of the American Medical Association, Chicago.

accepted by the Council. The description includes facts that the physician should have. It is a book that should be in the hands of every physician who prescribes medicines, and who wishes to know the facts regarding the newest remedies. It is the only book in which he can find information relative to proprietary medicines that are worthy of his patronage. It will protect the physician who makes use of it against the wiles of the promoters of products not worthy of his patronage. It would certainly be of use to the physician when the detail man calls on him, for if he were being importuned to prescribe or use samples of something which he had not heretofore used and which he was unable to find in N. N. R., he might ask the detail man why. In the nature of things few physicians are sufficiently expert in chemistry and allied sciences to be able unerringly to discriminate between the true and the false as regards many preparations that he is asked to prescribe.

2. *The Reports of the Council on Pharmacy and Chemistry.*—A medicament may be inadmissible to New and Nonofficial Remedies for various reasons; it may be worthless or irrational, its composition may be secret or indefinite, or it may be exploited under exaggerated or unwarranted claims or in a way otherwise detrimental to the public health and scientific medicine. Of these various reasons which make an article unacceptable, the manufacturer obviously may remove all except the first, viz., worthlessness or irrationality. Consequently, a preparation which has been presented for admission is not definitely rejected until after its proprietor has been informed of the objections to his product and has failed to bring the preparation in conformity with the Council's rules. When a preparation is found definitely inadmissible to New and Nonofficial Remedies, that is, when the proprietor cannot or will not make it acceptable, the Council prepares a report for publication. These reports are sent for publication to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, and later published in the "Annual Reports of the Council on Pharmacy and Chemistry." The more important of these are also published in the book, "The Propaganda for Reform in Proprietary Medicines."

3. *Useful Drugs.*—Since the domination of proprietary medicines, which was retarding medical advance and threatening therapeutic chaos, had been made possible only by the insufficient and inefficient instruction given in medical schools in subjects having to do with drugs, the Council appointed a "Committee on Medical Teaching" to secure the cooperation of teachers in materia medica, pharmacology and related branches. This committee has endeavored to effect an improvement in these courses of instruction. One of the results of this work was the selection of a list of drugs to serve as a basis of materia medica instruction and thus insure that medical students shall be better informed with regard to the therapeutic worth of a few well established drugs, rather than, as in the past, leaving school with a smattering of knowledge about many drugs. The outcome of these efforts is the publication of "Useful Drugs," a concise but thorough and up-to-date discussion of the actions, uses and dosage of the more important drugs. The list of drugs presented in this book is now the basis of instruction in many schools; and many state examining boards are confining their materia medica questions to the drugs in the list.

4. *Epitome of the U. S. P. and N. F.*—To encourage the use of official drugs and to make available an estimate of their therapeutic value, a committee of the Council prepared an abstract of the U. S. Pharmacopeia and the National Formulary. This booklet, the "Epitome of the U. S. Pharmacopeia and National Formulary," presents those portions of these books which are of interest to physicians, and in addition, gives a concise statement of the therapeutic usefulness of the drugs and preparations described in them.

5. *Patent Law Reform.*—Some of the worst abuses connected with the exploitation of proprietary medicines have been made possible by our patent and trademark laws and the method of their interpretation and enforcement. The Council therefore appointed a committee to study these laws and the various propositions advanced for their improvement. This committee has published, from time to time, reports on various phases of our patent and trademark laws and recently summarized these reports in an address[5] sent to the commissioner of patents and the interested congressional committees. It is hoped that by means of these reports physicians will be enabled to give intelligent support to a revision of the patent and trademark laws when legislation is proposed.

6. *Therapeutic Research.*—Through its Committee on Therapeutic Research, and with the aid of funds provided by the Board of Trustees of the American Medical Association, the Council has encouraged the investigations of questions which might lead to a better understanding of the action of drugs. These investigations are brought together in the annual reports of the Therapeutic Research Committee of the Council, and are an important addition to our knowledge of drug action.

In the past, the Council has in particular encouraged the investigation of the action and therapeutic value of widely used drugs regarding which our knowledge is still unsatisfactory. These investigations have included a study of the action of strychnin in cardiac disease, a comparison of the action of absorption and excretion of iodid preparations, a study of the pharmacology of the opium alkaloids, etc. Appreciating that the available knowledge of proprietary drugs is one sided in that it comes from investigations made by interested pharmaceutical concerns or from investigations made at the instigation of these firms, the Council is planning a comprehensive study of many of the synthetic drugs that have gained some vogue during recent years.

THE FUTURE

Medical research, and efficient instruction in therapeutics and related subjects, spell a diminishing influence of commercial medicine over rational therapeutics. The fact that the present shortage of German synthetics has not handicapped seriously the practice of medicine should be a lesson to American physicians for many years to come.

On the other hand, it must be remembered that the publicity given to the reports of the Council and to other contributions toward rational therapeutics by THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, the journals of the state organizations, and a few personally owned publications, is as nothing when compared with the persistent and wide publicity given to the propaganda of the proprietary houses. While a report setting forth the objections to a proprietary is published but once, the firm's laudatory pronouncement goes forth again and again until the Council's report is completely overwhelmed and forgotten. Not only do manufacturers of proprietaries keep in close touch with the practicing physician by means of house organs, special "literature," or by traveling representatives, but many of the firms, through the meritorious lines of pills, tablets, tinctures, etc., which they put out, obtain and hold the good will and confidence of a large proportion of the medical profession.

---

[5] Need for Patent Law Revision, A. M. A. Council on Pharmacy and Chemistry Reports, 1917, p. 130.

Furthermore, some of these firms not only gain the confidence of the medical profession through these high grade pharmaceuticals, but certain of their proprietaries may be of distinct therapeutic value and yet fail to be acceptable for New and Nonofficial Remedies, because they do not conform with the reasonable rules of the Council. These firms do not find it profitable to force the sale of their regular nonproprietary pharmaceuticals by unwarranted claims or objectionable methods, yet they may consider it good business to market certain proprietary products by means of claims which are extravagant and without warrant, and which will lead to indiscriminate use by the profession and the public. In a word, where there is one dollar spent on behalf of rational medicine, thousands are spent for the purpose of increasing the sale of preparations which directly or indirectly are a detriment to the public health, to medicine, and to the pocketbook.

That the day of the secret nostrum of the pseudochemical company is not yet past is well illustrated by the recent introduction of an asserted arsphenamin preparation called "Syphilodol." The A. M. A. Chemical Laboratory proved one form of this asserted French discovery to be essentially a pill of mercurous iodid. Another form of syphilodol (for intravenous administration) had all the characteristics of water, and appeared devoid of any potent ingredient. Though the advertising sent out by the promoters in regard to its composition was suspiciously evasive, the *Illinois Medical Journal* published an advertisement of "Syphilodol," which, possibly by a coincidence, appeared above an appeal to "Our Readers" to use wares advertised in that journal.

While such rank deceptions as "Syphilodol" are not common, there are more subtle deceptions that are even more dangerous. Types of widely exploited remedies of today comprise so-called ethical specialties composed of well known and established drugs (with "jokers" hidden away somewhere) or preparations which have a plausibly fascinating pseudo-scientific background of radiant energy, colloidal chemistry, nonspecific protein reaction, or something of the sort. The latter class of preparations in particular appeal to physicians who are striving hard to keep pace with modern science. Exposure of their fallacies requires most careful consideration on the part of the Council.

Progress toward a rational and scientific drug therapy must continue, and, therefore, it is important that the Council on Pharmacy and Chemistry should continue to make the investigation of proprietary medicines its chief work. Investigation of a proprietary medicine, however, and a report of such investigation are of value in direct ratio only to the number of physicians who read the report, endorse it and act in accordance with its conclusions. In order that you may determine to what extent those preparations which are admitted to New and Nonofficial Remedies deserve your interest and confidence, it will be worth while briefly to outline the rules which govern the Council in the admission of articles to New and Nonofficial Remedies.

RULES GOVERNING THE ACCEPTANCE OF ARTICLES FOR N. N. R.

Composition.—Rules 1 and 2, and in a measure 5, 7, and 9, deal with the composition of articles. Rule 1 requires that the quantitative composition of an article be furnished the Council for publication. Rule 2 requires that the manufacturer furnish methods whereby the composition of products that are definite chemicals or the potent constituents of mixtures may be determined. The Council does not require that the process of manufacture of an article be declared unless this becomes necessary in order to judge its composition. Rule 5 requires that statements with regard to the origin and source of an article shall be truthful. Rule 7 requires that for the guidance of the dispenser, the amounts of poisonous ingredients of a preparation be placed on the label. Rule 9 requires that if patent rights are claimed for a product, the Council be informed on this point.

That it is not only the right but also the duty of the physician to know the composition of what he prescribes for his patients is so generally admitted that few have attempted to market preparations of avowedly secret composition. When the Council first began its work, it was common to see chemical formulas or statements of composition published which a chemist or a pharmacist was able to pronounce at a glance as impossible.[6] It was not unusual to find that the promoter published "a formula" for his preparation, rather than "the formula."[7] Today, however, a more prudent, if not more honest, course is pursued. This gives a "formula" which is correct so far as it goes, but which fails to divulge the actual composition of a preparation. When it is considered that many physicians are not any too conversant with the chemistry and pharmacy of drugs, it is not surprising that some administered the proprietary "Venarsen," regarding the composition of which they had only the vague statement that it was ". . . a comparatively nontoxic organic arsenic compound, 0.6 gm. representing 247 mg. (3¾ grains) of metallic arsenic in chemical combination . . ." in the belief that a preparation similar to that first introduced as salvarsan was being used. That "Venarsen" contained its arsenic as sodium cacodylate—a notoriously inactive state of combination—does not justify the intravenous administration of a drug of unknown composition.

While for the present it probably is not feasible to require, on the part of those who manufacture medicinal preparations, such professional training as is required of those who prescribe and those who dispense them, it certainly is not too much to require, as does Rule 2, that a manufacturer shall be able to demonstrate that his preparation has the composition claimed for it. Nor is it sufficient for him to know that the ingredients claimed as constituents were used in the manufacture. The fallacy of this method of reasoning was furnished by the physician who reported that he had personally added the required amount of mercuric iodid for a batch of "Mercol" which, never-opening of the common duct in all patients with gallstones is not justifiable; yet I am convinced that unless this is done, a certain number of common duct stones will be overlooked and remain to cause subsequent symptoms. All of us can recall cases in which none of the classical symptoms of common duct stone were present, and yet operation revealed the presence of one or many calculi in that location.

---

[6] Puckner, W. A.: The Abuse of Chemical Formulas, Reports A. M. A. Chemical Laboratory 3: 7, 1910.

[7] The Formula for Glyco-Thymoline, J. A. M. A. 52: 147 (Jan. 9) 1909.

In view of the reported simplicity of the operation and, according to the literature, the ease and certainty with which a choledochotomy enables us to drag all common duct calculi from their lurking places, it is with some humiliation that I confess that I have, apparently, failed to detect common duct calculi in certain cases, even after opening the duct. Of our fourteen instances of secondary operation in which common duct calculi were detected, in five of the patients, stone or stones had previously been removed from the duct. Again, it may be asserted that these are instances of reformation or descent of calculi; but I am inclined to think that in some cases, at least, the stones were present at the time the duct was first opened, but were overlooked.

To summarize, it appears that:

1. Stones are present in the common duct in a considerable number of patients suffering from cholelithiasis.

2. A certain number of patients with stone in the common duct do not present symptoms sufficiently suggestive to justify exploration of the duct, and in some of these cases, palpation will fail to disclose the presence of the stone.

3. Even exploration of the duct sometimes fails to reveal the presence of calculi, though the previous and subsequent history of these patients may indicate or prove that stones were actually present.

The mortality in common duct cases subjected to operation is variously given at from 6 to 16 per cent. In our series, five patients died, giving a mortality of 10 per cent. In the series of gallbladder cases, exclusive of those showing calculi in the common duct, the mortality was about 2 per cent. Hence it is evident that the operative risk is more than fourfold as great in gallbladder cases. The obvious lesson is that in cholelithiasis cases operation should be performed early before the entrance or formation of the calculus in the common duct, and we are again reminded that cholelithiasis is essentially a surgical problem, and that medical temporizing is fraught with peril to the patients.

REPORT OF CASES

Case 1.—A white man, aged 42, gave a history of having suffered from pain in the epigastrium for several years. Five weeks before his admission to the hospital he had a severe attack of pain in the right hypochondrium followed by jaundice. The jaundice had steadily increased and was as intense as that following cancer of the head of the pancreas. Abdominal examination disclosed a large, smooth tumor in the region of the gallbladder. Operation revealed a large, distended gallbladder containing bile and some blood. Bleeding was profuse from the skin wound, abdominal wound and through the tube from the gallbladder. We were unable to control hemorrhage, and the patient died forty-eight hours afterward. Postmortem examination revealed three large gallstones packed one on the other in the pelvis of the gallbladder and cystic duct, the lower one partly extruding from the cystic duct and completely blocking the common duct.

In the light of the postmortem findings, I feel satisfied that if this patient had been operated on a few days after the onset of his symptoms, he might have been saved. The mechanical block was so great that it never could have been overcome by nature.

Case 2.—A white woman, aged 42, had suffered previous attacks of pain in the epigastrium, with slight jaundice. The present illness commenced four weeks before admission to hospital with an attack of pain, jaundice, chills and fever. On admission, jaundice still persisted. Operation was delayed a few days in the hope of improvement in the patient's condition, but as none occurred, operation was advised. A high right rectus incision revealed a gangrenous perforated gallbladder with pericholecystic adhesions. The gallbladder was enlarged to the size of a small grapefruit, and was buried in adhesions. There was free fluid in the abdomen, and as soon as the adhesions were partly released, pus and bile-stained fluid began to well up, and a perforation on the under side of the gallbladder was located. A large amount of pus and a number of stones were removed from the gallbladder. Stones were palpated in the common duct; but the general condition of the patient was so bad, and bleeding was so free where adhesions were released, that it was found impracticable to remove stones from the common duct. Free drainage was instituted in the gallbladder and neighboring region. The patient died seven days later from hemorrhage and exhaustion.

Case 3.—A white woman, aged 35, gave a history of having repeated attacks of epigastric pain and tenderness in the right hypochondrium. Three weeks before admission to the hospital she had a violent attack of epigastric pain, followed by a chill, temperature and jaundice. Abdominal examination on admission revealed a mass in the right hypochondrium, with jaundice, increased leukocytes and rise of temperature. A diagnosis of empyema of the gallblader was made and operation advised. Through a right rectus incision the gallbladder was exposed and found to be buried in a mass of omental adhesions. It was opened and found to contain pus and stones. We were unable to palpate anything in the common duct, although the head of the pancreas was markedly enlarged. The patient made an uneventful recovery with the exception of a persistent biliary fistula. Every time this fistula closed it would be followed by mild attacks of epigastric pain, jaundice and fever. We made the diagnosis of stone in the common duct and advised another operation six months later. At the second operation a stone could be palpated in the common duct under the head of the pancreas. A retroduodenal operation was done, the common duct rotated, and the stone excised from the back. Stitches were put in the duct and a small rubber drain put in the retroperitoneal space. As this patient already had a biliary fistula, we did not feel that a tube in the common duct was necessary. For two days following operation there was increased jaundice and a failure to discharge bile through the fistula. The patient began to have hemorrhage from the mucous membrane and fistula, and died four days later.

Case 4.—A white woman, aged 65, had been suffering with digestive disturbances, pain in the epigastrium, and tenderness over the right hypochondrium for several years, and had jaundice with some of her attacks. Five weeks before admission to the hospital she was seized with severe colicky pain, chill, fever and jaundice. On admission her general condition was bad and jaundice severe. A diagnosis of cholelithiasis with stone in the common duct was made. We thought it best to delay operation, hoping that the jaundice would improve. Two days after admission to the hospital she had nosebleed. As her condition did not improve, one week after admission we operated on her, removing stones from the common duct and gallbladder and draining the common duct. For a few days she improved; then there occurred oozing through the drainage tube and gauze drainage in the cavity. This oozing continued off and on for about three weeks until the patient finally died from hemorrhage and exhaustion.

Case 5.—A white woman, aged 40 years, was brought to the hospital two weeks after a severe epigastric pain, jaundice, chills and fever. Because of the intense jaundice we thought it was best to postpone operation. She was kept in the hospital on continuous saline for six weeks, and the jaundice slowly disappeared. Three months after this attack I advised operation, although the patient was not clear of jaundice; but because of slight recurrence of symptoms I feared a complete obstruction. On operation a stone was found in the gallbladder, and one at the head of the pancreas; the latter was easily pushed back into the common duct above the duodenum. The duct was opened and the stone removed. There was a tendency to hemorrhage in the common duct. For some reason the duct did not drain for the first twenty-four hours, and then bile appeared through the tube and drain. Jaundice rapidly increased after the operation, and the patient began to have hemorrhage from the stomach and mucous membrane. She died thirty hours later.

COMMENT

From the histories of our five fatal common duct cases, it is seen that hemorrhage was the striking feature of all. Bleeding was the direct or strongly contributory cause of death in every instance. It is also apparent that the most rapidly fatal hemorrhage occurs in those patients in whom, for some cause, an acute exacerbation is superimposed on a chronic jaundice.

It has come to be universally recognized that delay and expectant treatment are indicated in some types of abdominal infection, but I am more and more inclined to believe that this rule cannot be followed with safety in cases of infection with obstruction of the common duct. Acute jaundice is not so potent a factor in producing the hemorrhagic diathesis as chronic jaundice is;[7] therefore, hereafter, in common duct cases, the appearance of jaundice will be an important factor in my decision for immediate operation.

PNEUMOCOCCUS MENINGITIS

TREATMENT BY A SPECIFIC ANTIPNEUMOCOCCUS SERUM

LAWRENCE LITCHFIELD, M.D.
PITTSBURGH

In 1917 I reported that out of 134 cases of pneumonia diagnosed by myself and colleagues in western Pennsylvania during the preceding eighteen months, there had been fourteen cases of pneumococcus meningitis, several of which, being Type I, were treated by the intravenous and intraspinal use of the antipneumococcus serum of the Rockefeller Institute, with very interesting results but without any recoveries.[1] Since that time I have become more and more convinced that pneumococcus meningitis occurs much more frequently than has been supposed and far more frequently than it is recognized. Liebermeister has stated that in 25 per cent. of the cases of pneumonia there is a distinct suppurative inflammation in the membranes of the spinal cord, even though their gross appearance be unchanged.[2]

Evidence of meningeal irritation is often observed during the course of a pneumococcus infection, and these phenomena are too often treated as unimportant —as mere incidents of the general toxemia or as meningismus. But there are no signs or symptoms by which these warnings can be set aside as due merely to a so-called meningismus, by which is meant that there is no actual pathologic condition of the meninges; nor can a positive diagnosis of meningitis be made from the clinical signs and symptoms alone. A lumbar puncture should be made, with microscopic and cultural examination of the fluid obtained, in all cases which present a suspicion of meningeal irritation, and the eye grounds should be examined daily for evidence of choked disk. Lumbar puncture should be done and the eye grounds examined also in all cases of coma in which meningitis is possible, as in coma developing during a pneumonia, empyema, otitis media or sinusitis, for the reason that signs of meningeal irritation, such as abnormal or exaggerated reflexes, disappear if the coma is sufficiently profound. In rare cases, even after all these methods have been employed, we may still be in doubt. Clear, normal cerebrospinal fluid may be obtained by lumbar puncture although there is purulent inflammation of the meninges localized at higher levels. However, it is the rarest exception for cases showing signs and symptoms of meningeal irritation not to present positive laboratory findings on lumbar puncture.

Pneumococcus meningitis may develop during the course of lobar pneumonia or bronchopneumonia. It may develop after the usual onset suggestive of a pneumonia without the development at any time of any definite signs of pulmonary consolidation. Or, the meningitis may develop during convalescence from pulmonary pneumococcus infection and run a subacute course of several weeks' duration before the usual fatal termination. Meningitis may develop by extension from a pneumococcus infection of the frontal, sphenoid, or mastoid sinuses or even directly from the middle ear. Cases of recovery from proved pneumococcus meningitis have occurred very rarely. This is borne out by the following citations:

Elsner: We have no record of recovery in which the diagnosis of pneumococcus meningitis was positively established.[3]

Councilman: Where the pneumococcus or streptococcus was found, none of these cases recovered.[4]

Osler: All of our patients die.[5] The meningitis of pneumonia is almost always fatal.[6]

Stevens: Meningitis due to pneumococcal infection may be primary or associated with pneumococcal infection elsewhere. Symptoms are severe and the result fatal.[7]

Latham and Torrens: Meningitis in the course of a pneumonic septicemia is rapidly fatal.[8]

Lloyd: The prognosis is unfavorable.[9]

Pye-Smith and Beddard: Meningitis as a complication of lobar pneumonia is usually purulent and uniformly fatal.[10]

Bovaird: Such complications as meningitis . . . are always fatal.[11]

Delafield: Pneumonia-acute meningitis is a very infrequent complication but a very fatal one.[12]

Hall: Pneumococcic meningitis is practically always fatal.[13]

Babcock: Meningitis is a very serious complication of pneumonia and usually proves fatal in from two to four days."

Whatever may be the route by which the lungs are invaded in pneumococcus infection, whether by extension through the bronchial tree or by distribution from the blood stream, a blood stream invasion with a widespread distribution of the pneumococci throughout the body is the rule very early in the disease. This being the case, it only remains for certain local conditions, as yet unknown, to be favorable, and there develops a suppurative meningitis, mediastinitis, pleuritis, peritonitis, arthritis, bursitis, otitis, myositis, mastoiditis, thrombophlebitis, sinsusitis, conjunctivitis or other complications.

During the fulminant onset of the epidemic of pneumonia at Camp Grant in the fall of 1918, the necropsies of Captain Hirsch furnished abundant evidence for the conception of pneumococcus infection just given, the presence of pneumococci in the cerebrospinal fluid being repeatedly demonstrated when there was no clinical or histologic evidence of meningitis. We cannot say that these patients would have developed pneumococcus meningitis if they had lived long enough, but we know that at least one prerequisite was present. In my opinion the presence of pneumococci in the cerebrospinal fluid is an indication for the intraspinal use of a bactericidal antipneumococcus serum such as the Kyes serum; but the presence of bacteria alone, without evidence in the cerebrospinal fluid of an inflammatory process, even though accompanied by signs and symptoms of meningeal irritation, does not prove that there is or ever will be a meningitis, although it makes such a development highly probable.

The results obtained by Capps at the Cook County Hospital during the winter of 1916-1917,[15] and at the base hospital at Camp Grant during the winter of 1917-1918 in the treatment of pneumonia with the antipneumococcus serum of Dr. Preston Kyes, made me very anxious to try this serum in cases of pneumococcus meningitis. Through the courtesy of the University of Chicago and the enthusiastic cooperation of Dr. Kyes, an abundance of serum was placed at my disposal; the recent epidemic furnished the cases.

The epidemic of influenza, so called, began at Camp Grant, September 19. In three or four days the victims of influenza began to develop pneumonia. October 11, my morning report showed 1,508 cases of pneumonia in the hospital. During the eight weeks we had over 10,000 cases of influenza with about 2,700 cases of pneumonia. The medical officers were asked to report [illegible]ce any cases show[illegible] signs of meningeal irritati[illegible] a month a[illegible] onset of the epidemi[illegible] [illegible]tis began to [illegible] rtion to [illegible] smaller [illegible] ber of [illegible] appear- [illegible] ance of [illegible] many [illegible] time to [illegible] ops very [illegible] and in this [illegible] the virulence [illegible] be diminished.

We had the opportunity of treating ten cases of typical pneumococcus meningitis with the Kyes serum. The clinical diagnoses in all of these cases were verified by consultants, and the etiology was established in each case by abundant laboratory findings. Of the ten patients, five died and five recovered. As far as the meningitis was concerned, there was no difference clinically between the condition of the patients who recovered and the condition of those that died. Some of the patients with the most intense symptoms of meningitis recovered. Some of the milder cases ended fatally owing to extensive involvement of other organs, as shown by necropsies. The treatment was the same in all cases.

REPORT OF CASES

For the sake of brevity only the briefs of the successful cases are here given:

CASE 1.—P. O., aged 24, colored, whose occupation was that of laborer, admitted to the hospital Oct. 3, 1918, had had measles, mumps, malaria, pneumonia and typhoid fever—all in childhood. On examination there were restricted breath sounds in the left lower lobe and a few râles. The abdomen was flat; the liver had no enlargement; the spleen was negative, the reflexes were negative, and the nervous and osseous systems were negative.

The present trouble began three days before admission to the hospital, with chills and fever, pain in the back, sore throat, headache, constipation and violent paroxysms of coughing.

Lobar pneumonia was diagnosed, October 15, in the right lower lobe. There was no herpes.

October 22, the condition was good. There was still some consolidation in the right lower lobe with fine râles.

October 27, the patient complained of pain in the chest and the lumbar region. The temperature rose to 103; the pulse was 88 with signs and symptoms of meningitis.

October 28, 10 c.c. of spinal fluid were withdrawn and 10 c.c. of Kyes serum were given intraspinally. The spinal fluid was clear; the white cell count was 720 per cubic millimeter. Sugar and globulin were negative. Direct smear and culture were negative. Blood count revealed 28,800 leukocytes.

October 29, the spinal fluid showed a white cell count of 1,810 per cubic millimeter. Globulin and sugar test were negative. Direct smear disclosed a few organisms, morphologically pneumococcus. Culture revealed a pneumococcus.

Kyes serum was given daily intravenously and intraspinally from October 28 to November 24.

October 31, the patient still had opisthotonos, ankle clonus, Babinski reflex and fixed pupils.

November 26, his condition was practically normal, without evidence of any sequelae.

December 1, his eye grounds and reflexes were all normal except for rather marked general cutaneous hyperesthesia.

CASE 2.—E. B., aged 22, colored, whose occupation was that of farmer, was admitted to the hospital Oct. 11, 1918. The family history was good. The patient had had measles, whooping cough, malaria and pneumonia in childhood. The present illness began October 10, with a severe headache, chills and fever. The following day herpes developed on the lips.

October 16, signs and symptoms of meningitis were confirmed by spinal puncture. Kyes serum was given intraspinally and intravenously, from 5 to 10 c.c. at a dose. There was a septic type of temperature, ranging from 101 to 104; then from 97 to 103, gradually reaching normal about November [illegible] The pulse varied between 85 and 100 until October 20, after which time it ranged between 60 and 85; after November 1 it was practically normal. October 21, the Kernig sign and the Babinski reflex were present and there was rigidity of the neck. October 22, there was a severe chill. October 23, acute bilateral tonsillitis appeared. October 26, there was delirium and opisthotonos. Laboratory reports, October 22, were that the spinal fluid was very turbid and the cell count 4 [illegible] Direct smear gave a pneumococcus. Cultures were negative.

[illegible] D. Appleton & Co.,

[illegible] Lobar Pneumonia with [illegible] 495-501 (July) 1918.

October 26, the fluid was turbid, white cell count 2,850, sugar negative, globulin positive, direct smear pneumococcus, culture negative.

October 29, a culture from the cerebrospinal fluid was reported positive for the pneumococcus. This patient received Kyes antipneumococcus serum from October 16 to October 29, intravenously and intraspinally, receiving in all 105 c.c.

December 1, his eye grounds and reflexes were normal, and his general condition was excellent. There was no evidence of sequelae.

Case 3.—W. E. F., aged 32, white, whose occupation was that of cook, was admitted to the hospital, Oct. 13, 1918. The patient's mother died in 1914, from cancer of the breast. The family history was otherwise negative. The previous personal history was good. The heart and lungs were negative. The genito-urinary system was negative. The special senses were normal. The present illness began, October 10, with a severe cold in the head, accompanied by headache, backache, flushed face, weakness and vomiting. The vomitus was blood-streaked. The temperature on admission was 102; pulse, 88; respiration, 28. There were râles at the base of both lungs. The reflexes were normal. The patient became delirious at once. October 15 the headache was still severe. Pneumonia with pleurisy was diagnosed in the right lower lobe.

October 21, the neck was stiff, the pupils were contracted and fixed, and the patient was semicomatose. The temperature was 100; respiration, 32. The laboratory report on the cerebrospinal fluid was white cell count 40 per cubic millimeter. Direct smear gave a few gram-positive, lancet-shaped diplococci. A culture revealed pneumococcus in pure culture. On the 26th, the spinal fluid was slightly cloudy, the white cell count was 180; sugar was positive, and globulin negative. Direct smear and culture were both negative.

From October 21 to the 26th, the temperature ranged from 100 to 103; the pulse for the most part, 90 to 100; respiration, from 30 to 40. There was gradual improvement until temperature, pulse and respiration became normal after November 1. Kyes antipneumococcus serum was injected intraspinally, October 21, 23 and 26. A direct improvement was noted, both mental and physical, after October 23.

Four doses of 5 c.c. each were given intraspinally and 5 c.c. of the same serum were given intravenously, once or twice daily, during the course of the pneumonia.

December 1, the eye grounds and reflexes were normal, the general condition was excellent, and there was no evidence of sequelae.

Case 4.—M. O., aged 22, colored, whose occupation was that of farmer, was admitted to the hospital, Oct. 27, 1918. The father had died from tuberculosis. The personal history was negative except for frequent tonsillitis. The present trouble began October 25, with chill, sore throat, stiff neck, aching all over, cough and some delirium, swollen tonsils, and follicular exudate. The heart and lungs were negative. Later, there was consolidation of the left lower lobe. The genito-urinary system was negative. The special senses were normal. The spleen was not palpable. The skin reflexes were normal.

November 14, there was diagnosis of meningitis. The Kernig sign still remained on the left side, the neck was stiff, and there was a suggestion of the Brudzinski sign. There was no Babinski or Oppenheim reflex; the pateller reflexes were sluggish. The abdominal reflexes of the left upper and lower quadrants and the left cremasteric were absent. Lumbar puncture revealed the cerebrospinal fluid to be under moderate pressure.

November 17, the spinal fluid gave a white cell count of 1,300; sugar was negative, and globulin was positive. Direct smear revealed numerous gram-positive diplococci; culture gave a pneumococcus. November 26, the white cell count was 6,400; sugar was positive, and globulin was positive. Direct smear was negative.

November 28, the cell count was 3,800; sugar was positive; globulin was positive; smear and culture were both negative.

The temperature ran a septic course, from 100 to 103; pulse, 88 to 108; respiration, 20 to 26, for this period of about two weeks. This patient was desperately ill and received 15 c.c. of Kyes serum intraspinally twice daily at first and later once daily, with 5 c.c. intravenously twice and later once daily. He received in all 453 c.c. On several days he received three intraspinal injections within twenty-four hours on account of the severity of the meningeal symptoms.

Leukocytosis varied between 16,000 and 18,000, but only four counts were made and those between October 20 and November 15.

December 2, the eye grounds and reflexes were normal. The patient's general condition was excellent. There was no evidence of sequelae. Temperature, pulse and respiration were normal. The patient ate and slept well.

Case 5.—N. J. S., aged 25, white, whose occupation was that of farmer, was admitted to the hospital, Dec. 9, 1918. The family history was negative. The personal history gave the usual diseases of childhood. The patient had had "clinical influenza" in October and pneumonia a year previous to the present attack. There was no venereal history. The onset was accompanied by sore throat and headache, December 6, headache being so severe the previous night as to prevent sleep. The examination on the date of admission to the hospital was negative, except that the tonsils were injected and probably slightly swollen. The patient walked to the hospitla. December 11, the patient still complained of severe headache, mostly frontal; was rational and answered all questions promptly. On examination, the suboccipital muscles were stiff and the head slightly retracted. Tendon reflexes were exaggerated and marked Kernig and Babinski signs were present; the abdominal muscles were rigid, and general hyperesthesia was marked. Fifty c.c. of spinal fluid were withdrawn and 30 c.c. of antimeningococcus serum were introduced intraspinally. The spinal fluid gave a cell count of 5,400 per cubic millimeter; sugar was negative, and there was a slight increase of globulin. Direct smear gave a few gram-positive, lancet-shaped diplococci, morphologically pneumococci. Culture was negative after forty-eight hours.

December 11, after laboratory report was made on the morphology of the bacteria in the spinal fluid, 60 c.c. of spinal fluid were withdrawn and 20 c.c. of Kyes serum were introduced intraspinally and 5 c.c. intravenously. From this time until Dec. 28, the patient was continually delirious. Neck rigidity continued, with retraction of head until Dec. 17, when relaxation began to be evident. Severe headache was usually complained of during this period, and the reflexes continued to be exaggerated. The temperature ranged between 100 and 103, with slight morning remissions, until December 17, when decided remissions down to 99 began to occur, with afternoon rises to 102. The pulse ran between 60 and 80, and respiration, though often stertorous, was not affected in frequency. From December 17 until the 28th, symptoms gradually disappeared, until on the latter date the patient was fairly rational and was able to state on being questioned that he had no recollection of what had occurred up to that time; that he remembered nothing of the intraspinal injections. Laboratory reports on examinations of spinal fluids withdrawn when intraspinal medication was given revealed: December 13, cell count 16,000 per cubic millimeter; sugar was negative and globulin was positive. Direct smear gave gram-positive, lancet-shaped diplococci, morphologically pneumococci; culture was negative. December 16, the cell count was 4,000 per cubic millimeter; sugar was negative, and globulin showed a large increase. Direct smear disclosed many gram-positive diplococci, many of which were intracellular; culture revealed pneumococci. December 19, direct smear showed a few gram-positive diplococci, morphologically pneumococci, but culture was again negative.

After the first intraspinal injection of 30 c.c. of antimeningococcus serum, on December 11, 20 c.c. of Kyes antipneumococcus serum were injected intraspinally twice daily until December 17; 5 c.c. were also given intravenously twice daily.

December 18 and 19, 20 c.c. of serum were given intraspinally and 5 c.c. intravenously, both once daily, after which serum administration was discontinued, though the patient continued to have a slightly increased temperature between 99 and 100 until December 28, when it reached normal and remained so. Muscle rigidity and exaggerated reflexes have gradually been disappearing until at the present time (January

31) all such symptoms have virtually disappeared; and the patient can be said to have made a complete recovery. He has been up and about the ward for the last two weeks. December 15, ophthalmic examination showed a moderate swelling of the disks. December 26, there was a slight enlargement of veins but no tortuosity. There was a very slight swelling of the disks. It should be noted that no pulmonary involvement occurred in this case.[16]

All of these patients were treated in the open air, with the usual routine of digitalis and, when necessary, salines, morphin, bromids, atropin, epinephrin nd caffein.

e fragmentary and incomplete character of these istories is due to the stress of work in the hospital during this epidemic. As far as they go, however, they are absolutely dependable.

The laboratory work was done under the able direction of Capt. E. F. Hirsch, in charge of the pathologic service of the base hospital.

COMPARATIVE PROGNOSIS OF TUBERCULOUS LESIONS OF RIGHT AND LEFT LUNG

ORT OF FIVE HUNDRED CASES

LOUIS MARK, M.D.
MOUNT VERNON, OHIO

During the routine reexamination of patients in the women's service at the Ohio State Sanatorium, it had n my observation that cases with the greater amount tive involvement in the left lung made progress ower toward quiescence than cases in which the right lung was more involved. A few years ago, while doing a large number of necropsies on tuberculous subjects, I repeatedly noticed that in the majority of cases of bilateral tuberculosis the right lung showed considerable involvement at the apex, with a marked tendency toward fibrosis; whereas the left lung was usually heavily infiltrated from the apex to the base, with a thickening of the pleura and very firm pleural adhesions but with very little fibrosis of the lung. From this I judged that the initial lesion had been in the right lung, but that the left lung showed the greater amount of active involvement.

Since that time, in closely observing roentgenograms of moderately advanced and of advanced cases, I have noticed that the right lung shows evidence of heavy fibrosis much more frequently than does the left lung. In checking up a number of pneumothorax cases I found that in 75 per cent. the left lung was the one that had to be collapsed; and if we considered the cases in which pneumothorax was advised but patients would not consent to it, the percentage of leftsided cases would be far greater than this.

With the assistance of our statistician, Miss L. A. Steeves, I compiled the results secured in the treatment of the last 350 patients admitted to the sanatorium whose length of stay was six months or longer, and also of the last 150 patients admitted whose stay was one month or less—who were classed as far advanced cases on admission and were discharged as too sick for our sanatorium routine. Our findings compare fairly closely with the report given by Tecon and Aimard,[1] except for the fact that we found a greater percentage of left lung infections in the advanced cases than they. In their report they state that in 77 per cent. of their pneumothorax cases the left lung was the one collapsed, and that of 83 per cent of incipient cases that were apparently healed, only 7.5 per cent. were of the left lung. They also mention that 14 per cent. of left lung cases had grown worse as compared with 6 per cent. of right lung cases.

TABLE 1.—LUNG INVOLVEMENT IN ONE HUNDRED AND FORTY-EIGHT FAR ADVANCED CASES IN WHICH THE PATIENTS WERE DISCHARGED AS TOO SICK

	Number	Per Cent.
Right lung	59	40
Left lung	89	60
Both lungs	89	60
Right most	37	25
Left most	52	35
Left lung only	37	25
Right lung only	22	15
Right cavity	37	25
Left cavity	35	24

Owing to the lack of hospital facilities, the institution is unable to take care of far advanced cases needing absolute bed care. If a patient is unable to go to the dining hall for his meals, owing to a constant high fever, marked constitutional symptoms, hemorrhages, or general weakness, which may necessitate absolute bed care for a long period of time, he is discharged as too sick for our routine. It is from this group that Table 1 was compiled.

In reviewing the 148 cases that were discharged as unimproved, their stay at the institution being less than one month, there were 40 per cent. in which the right lung was involved either alone or with some involvement of the left lung, and 60 per cent. in which the left lung was involved alone or with some involvement of the right lung. Sixty per cent. of the total showed evidence of active tuberculosis in both lungs. Of the number of cases in which both lungs were involved, 25 per cent. of the total showed evidence of the greater amount of involvement in the right lung and 35 per cent. evidence of the greater amount of involvement in the left lung. Twenty-five per cent. showed the left lung alone involved, and 15 per cent. the right lung. The right lung showed evidence of cavity formation in 25 per cent. of the cases, as compared with 24 per cent. in the left lung.

TABLE 2.—MALE AND FEMALE PATIENTS WHOSE STAY WAS SIX MONTHS OR LONGER

	Male		Female	
Age	Number	Per Cent.	Number	Per Cent.
6 to 10	3	1.5	1	0.7
11 to 20	39	20.4	32	20.9
21 to 30	83	43.5	84	54.9
31 to 40	47	24.6	17	11.1
41 to 50	13	6.8	18	11.7
51 to 60	4	2.2	1	0.7
61 to 70	2	1.0	0	0.0
Total	191		153	
	344			

In analyzing these figures, it seems that in far advanced cases of active pulmonary tuberculosis the percentage of left lung infections is greater than of the right lung, whereas it has been proved that the majority of early tuberculous cases present right lung infections.

---

16. The h[illegible] of this [illegible] well as i[illegible] t aid throughout the work, w[illegible] d by [illegible] . Gra[illegible] waukee, my valued assistant [illegible] ese; [illegible] e.

1. Tecon and Aimard: Pulmonary Tuberculous Processes, Rev. Méd. de la Suisse Rom. **37**: 45 (Jan.-Feb.) 1917.

AGE

In analyzing the age of the patients, the greatest percentage of tuberculous infections in both male and female occurred between the ages of 21 and 30, there being 43.5 per cent. male and 54.9 per cent. female within these age limits. In the female, the ages between 11 and 20 rank second in percentage, with 20.9 per cent.; whereas, in the male, the ages between 31 and 40 rank second, with 21.6 per cent.

CLASSIFICATION OF CASES ON ADMISSION

Of the 191 male patients, 12 per cent. were classed on admission as incipient, 67.6 per cent. as moderately advanced, and 20.4 per cent. as advanced. Of the 153 female patients, 26 per cent. were classed as incipient, 54.9 per cent. as moderately advanced, and 19.1 per cent. as advanced. The National Tuberculosis Association standard of classification was used, cases being considered Turban I, II or III, respectively. From Table 3 we see that there were more than twice as many female incipient cases in comparison with the number of male incipient cases, and less female moderately advanced and advanced cases than there were male.

TABLE 3.—CLASSIFICATION OF CASES ON ADMISSION

	Male			Female		
	Number	Per Cent.	Per Cent. of Total	Number	Per Cent.	Per Cent. of Total
Incipient, Turban I	23	12.0	6.7	40	26.0	11.6
Moderately advanced, Turban II	129	67.6	37.5	84	54.9	24.4
Advanced, Turban III	39	20.4	11.4	29	19.1	8.4
Total	191			153		
	344					

LUNG INVOLVED

In reviewing Table 4 we find that there were 172 cases in which the right lung showed the greater amount of involvement and the same number in which the left lung was more involved. In the male, the incipient cases showed 8.1 per cent. right lung infections as compared with 5.2 per cent. left; the moderately advanced cases, 45.3 per cent. right as compared with 29.5 per cent. left; and the advanced cases, 9.3 per cent. right compared with 13.4 per cent. left. In the female incipient cases there were 12.2 per cent. right compared with 11.6 per cent. left; moderately advanced cases, 19.2 per cent. right compared with 29.1 per cent. in the left; and in the advanced cases, 5.9 per cent. right compared with 11 per cent. in the left lung.

TABLE 4.—INVOLVEMENT OF RIGHT AND LEFT LUNGS

	Right			Left		
	Number	Per Cent.	Total Per Cent.	Number	Per Cent.	Total Per Cent.
Incipient:						
Male	14	8.1	4.2	9	5.2	2.6
Female	21	12.2	6.1	20	11.6	5.8
Moderately advanced:						
Male	78	45.3	22.7	51	29.5	14.8
Female	33	19.2	9.6	50	29.1	14.6
Advanced:						
Male	16	9.3	4.6	23	13.4	6.7
Female	10	5.9	2.8	19	11.0	5.5
Total	172			172		
	344					

In analyzing this table, we find that in the incipient cases the percentage is greater on the right side, and in the male the percentage of moderately advanced right side cases is almost 2:1, as compared with the left, but in the female the ratio of left to right-side infections is about 3:2. In the advanced cases the percentage of right side infections as compared with left is exactly reversed to the percentage of male incipient cases, and the advanced cases in the female show a left to right proportion of 2:1. The greater percentage of right-sided cases in the incipient stage of both male and female, and the moderately advanced stage of the male, is counterbalanced by the moderately advanced left-sided female cases and far advanced cases of both male and female, making the percentage of left and right equal when all stages of the disease are considered.

TABLE 5.—LUNG INVOLVEMENT IN THREE HUNDRED AND FORTY-FOUR CASES

	Right Lung Only		Left Lung Only		Total Both Lungs		Both Lungs			
							R. Most		L. Most	
Total Cases	No.	Per Cent.	No.	Per Cent.	No.	Per Cent.	No.	Per Cent.	No.	Per Cent.
344	40	11.3	35	10.2	269	78.5	133	38.6	136	39.9

Of the 344 cases, 11.3 per cent. had the right lung alone involved, 10.2 per cent. the left lung alone involved, and 78.5 per cent. showed both lungs involved, 38.6 per cent. having the greater involvement in the right lung and 39.9 per cent. showing the greater amount of involvement in the left lung.

CONDITION ON DISCHARGE

Of the patients discharged as arrested, 16.6 per cent. were right-side cases; whereas there were only 8.8 per cent. left-side cases. The proportion of right-side as compared with left-side cases in the male was 4:3, and in the female the proportion was 4:1. Of the female cases there were only 4.5 per cent. of left-side cases discharged as arrested, and in the male 13.2 per cent. The male cases discharged as apparently arrested showed a proportion of right to left of about 3:1; whereas in the female cases the proportion was 2:1. There were 7.2 per cent. apparently arrested cases of left lung infections in the male and 10.1 per cent. in the female. The percentage that reached the stage of quiescence was greater in the left of both male and female than in the right, the proportion in the male being 3 left to 2 right, and in the female almost 2:1. The percentage of improved and unimproved in the male cases was greater in the left, whereas the right lung improved in the greater percentage of cases in the female. The percentage of unimproved in the female showed a proportion of about 2 left to 1 right.

TABLE 6.—CONDITION ON DISCHARGE

	Male				Female			
	Right		Left		Right		Left	
	Number	Per Cent.	Number	Per Cent.	Number	Per Cent.	Number	Per Cent.
Arrested	19	17.6	11	13.2	10	15.6	4	4.5
Apparently arrested	22	20.3	6	7.2	11	17.2	9	10.1
Quiescent	23	21.3	26	31.3	15	23.4	34	38.2
Improved	23	21.3	20	24.1	23	35.9	27	30.3
Unimproved	21	19.5	20	24.1	5	7.8	15	16.9
Total	108	56.5	83	43.5	64	41.8	89	58.2
	191				153			

Table 6 shows very clearly that in the male cases there is a greater tendency toward arrestment or apparent arrestment than in the female, and that in both male and female the right lung becomes arrested or apparently arrested far more often than does the left lung. The left lung cases show a great tendency toward becoming quiescent, but the progress from this stage seems to be much slower in the left than in the right.

SPUTUM ANALYSIS ON ADMISSION AND DISCHARGE

The sputum specimens of the right incipient cases of the male that were positive for tubercle bacilli on admission all became negative before discharge; but in both the right-side and the left-side cases of the female incipient cases the sputum remained unchanged.

TABLE 7.—SPUTUM ANALYSIS ON ADMISSION AND DISCHARGE

	Male				Female			
	Right		Left		Right		Left	
Incipient:	Pos.	Neg.	Pos.	Neg.	Pos.	Neg.	Pos.	Neg.
Admission	5	9	4	5	5	16	5	15
Discharge	0	14	3	6	5	16	5	15
Moderately advanced:								
Admission	63	15	45	6	17	16	33	17
Discharge	57	21	42	9	13	20	37	13
Advanced:								
Admission	15	1	21	2	8	2	16	3
Discharge	14	2	21	2	7	3	17	2

In the moderately advanced and advanced left-side female cases there was a greater number with positive sputum on discharge than on admission.

AVERAGE LENGTH OF STAY IN MONTHS

The average length of stay of the incipient cases was about 8.7 months. The left female cases stayed the longest time, averaging 10 months. The length of stay of the moderately advanced cases averaged 9.9 months, the female cases averaging about one month longer than the male. The average length of stay of the advanced cases was about 9.1 months, the male left-side cases averaging the longest stay, which was 11 months.

In 15.1 per cent. of the cases the left lung got worse and in 12 per cent. of cases the right became worse. The left-side cases averaged about 0.4 degree higher temperature on admission than did the right-side cases, and averaged about two weeks longer for the temperature to drop to *normal* or subnormal, in cases which reached this stage. The left-side cases were more persistent in presenting a constant or an occasional afternoon increase of temperature. There was no apparent difference in the pulse rate of either right-side or left-side cases, and all cases averaged about four months for the pulse to drop to 90 or lower at all times during the day in those that reached the point of quiesence, apparent arrestment or arrestment.

TABLE 8.—AVERAGE LENGTH OF STAY IN MONTHS

	Incipient		Mod. Advanced		Advanced	
	Right	Left	Right	Left	Right	Left
Male	8.5	7.8	9.8	9.1	7.8	11.0
Female	8.7	10.0	10.6	10.1	8.7	8.8

The average gain in weight of the right-side cases was 12.8 pounds as compared with 14.8 pounds of left-side cases.

I have repeatedly noticed that patients who gain a great deal of weight very rapidly will not stand exercise as well as those in whom the gain in weight is not so rapid, or in whom there is not very much gain in weight. The patients who gained weight very rapidly showed a tendency to become tired and to have a rise in temperature with a very rapid pulse on the least exertion, and they had to be given absolute bed care for a longer period of time, in spite of their gain in weight and their apparent rapid improvement, than patients with the same amount of involvement in the right lung. In patients who gain in weight very rapidly, exercise must progress slowly; but once they attain the point of a resistance against a small amount of exercise, then graduated exercise progressing fairly rapidly may be instituted.

All patients were examined about every two months, the weight was taken every week, and records were kept of the daily conduct of the patient.

The percentage of cases that showed albumin in the urine was very small. Two of the patients showed evidence of sugar in the urine on admission and on discharge, and another patient showed sugar on admission but no sugar on discharge.

CONCLUSIONS

In the far advanced cases that were discharged from the institution as too sick for our routine, the percentage of left-side cases was greater than of right. From this we can plainly judge that in this type of case, when the left lung shows the greater amount of involvement, the prognosis of building the person back to some working capacity or of bringing the chest to at least a point of quiescence is far less than of the right lung cases.

In the case of patients whose stay was six months or longer, the percentage of left-side cases which became apparently arrested or arrested was far less than of right-side cases, even though the average length of stay was slightly longer. This would also point to the fact that the prognosis of left lung infections, even in incipient cases, is considerably less favorable than of right-side cases. To say that a left lung infection will not improve or will not become quiescent may not always be true; nevertheless it is a fact that these cases make much slower progress than the right-sided cases, and the percentage of these patients returned to a normal working capacity or to a state of health in which they may enjoy life is far less than of those with right-side involvement.

Patients with left-side involvement should be given a longer period of absolute bed care; and when exercise is begun, it should be prescribed guardedly and increased slowly. A number of these patients may present a normal or a subnormal temperature with only a slight variation between morning and afternoon and a fairly constant pulse, but on physical examination will show little tendency toward fibrosis, and when exercise is prescribed may stand it very well for a while but will have a return of clinical symptoms, which is their first warning of a possible breakdown, much sooner than a patient with the same amount of involvement in the right lung.

There are several reasons which may account for the more rapid spread of a tuberculous focus in the left lung than in the right. The left lung is considerably smaller than the right and has but two lobes. The bronchus leading to the left lung forms a more obtuse angle and is much smaller than the right bronchus. There are two fissures on the right and only one on the left. The interlobar clefts fence in the infection and prevent one lobe from becoming infected by the other except through the regular channels along the bronchial tree. This fencing by the interlobar pleura is repeatedly seen on roentgenograms of the chest and also in the sectioning of tuberculous lungs at necropsy.

SUMMARY

1. The amount of involvement being equal, the prognosis of lesions of the left lung is not as good as of the right.
2. Prognosis of the male cases is better than of the female cases.
3. There is less tendency toward fibrosis in the left as compared with the right lung.
4. Patients with active tuberculous lesions in the left lung require absolute bed care over a longer period of time than the right-side cases to produce the same results.
5. Rapid gain in weight, especially of the left-side cases, does not always mean rapid progress toward quiescence.
6. Artificial pneumothorax of the left lung is more frequent than of the right.
7. The greater number of incipient cases show tuberculosis of the right lung, and the greater number of advanced cases in the left lung. The percentages of right and left lung cases are equal when all stages of the disease are considered.

A REPORT OF SIXTY CASES OF WOUND DIPHTHERIA *

JOE A. HARTSELL, M.D. (CONCORD, N. C.)
First Lieutenant, M. C., U. S. Army

WITH BACTERIOLOGIC APPENDIX BY

MYRON L. MORRIS, M.D. (NEW YORK)
Major, M. C., U. S. Army

FRANCE

I. CLINICAL

By Lieutenant Hartsell

In reporting these cases of wound diphtheria it is necessary, first, to say a word about throat diphtheria occurring in our hospital. During the fall and early winter, throat diphtheria appeared; and while it never approached a real epidemic, its incidence was greater than would be expected in a hospital community. Our hospital during this time furnished more cases than any other unit, and some weeks furnished about two thirds of all the cases in a center of from eight to twelve hospital units. In our hospital, Ward A-1 furnished most of the cases. The first case of throat diphtheria appeared in Ward A-1, Oct. 14, 1918. Up to November 15, five other cases of throat diphtheria appeared. November 16, a general throat culture of the entire ward disclosed five carriers. In December, five clinical diphtherias and four carriers were found. January 2, another carrier was found. From October 14, to date, February 1, therefore, Ward A-1, with patients ranging from eighty to 150, had eleven true throat diphtherias and ten carriers, and it was in this ward that the outbreak of wound diphtheria centered.

The first case of wound diphtheria appeared in a large debrided wound of the thigh. This wound was of several weeks' standing and had been doing well under Carrel-Dakin treatment until November 20, when it suddenly showed a gray-black membrane quite typical of wound diphtheria. Cultures this date and December 9 and 12 were negative. December 13, however, showed a positive culture. Subsequent cultures were positive up to December 31, and then remained negative.

This discovery focused attention on wounds in this ward as the possible source of the continual throat diphtheria. Cultures of all the wounds in the ward were taken on the 13th, and eighteen were found positive. The ward was immediately placed under strict quarantine and the most careful wound technic established.

The large number of cases in Ward A-1 raised a question as to the other wards. Cultures of the patients in these were then taken about once each week, and to date forty-one cases have been found in the other fourteen surgical wards, each ward having from thirty to sixty patients. All these cases picked up in the other wards were immediately transferred to Ward A-1, partly for better isolation and partly for more intensive treatment and more systematic study as a group. The cases in the other wards were irregularly scattered. Some wards had none, others from one to five. In some wards new cases would be found on each successive weekly test, although the patients found the week before were removed at once. Some wards showed a case or two on the third test which had been negative on the previous two. Three cases were picked out of a group of 100 surgical patients who were transferred to our hospital from another unit in the center.

REPORT OF CASES

CASE 1.—Sergeant T. was admitted to Ward A-1, Oct. 8, 1918, with a gunshot wound of the right thigh. November 29, the wound showed a dirty gray membrane; cultures on this date and on December 9 and 12 were negative. December 13, wound culture was positive. Cultures twice weekly remained positive until December 31, during which time the patient had received four doses of diphtheria antitoxin of 20,000 units each. On this date the Carrel-Dakin treatment was discontinued and the wound cleaned with a 1 per cent. soap solution, ether and alcohol and painted with U. S. P. tincture of iodin once daily. All subsequent cultures have remained negative. The Schick test, December 17, was negative.

CASE 2.—Private N. was admitted to Ward A-1, October 7, with a shrapnel wound of the right thigh. The Carrel-Dakin treatment was used until December 6. A dichloramin-T dressing was then used until the 13th, when wound culture showed positive for diphtheria. The wound was then treated daily with tincture of iodin as in Case 1, and on December 18 wound culture was negative and cultures twice weekly since then have remained negative. The Schick test, December 17, was negative.

CASE 3.—Private G. was admitted to Ward A-1, November 3, with a large, infected, debrided wound of the buttocks, which was treated by the Carrel-Dakin method. December 13, it showed a positive wound culture and remained positive until December 31. January 1, the Dakin tubes were removed and the wound cleaned and painted with tincture of iodin. Since then all cultures have been negative. The Schick test, December 17, was negative.

CASE 4.—Private K. was admitted to Ward A-1, October 4, with a gunshot wound of the right leg with a compound comminuted fracture of both bones. December 13, it showed a positive culture. December 20, culture was negative, and all subsequent cultures were negative. This wound was treated entirely by the Carrel-Dakin method. The Schick test was negative, December 17.

CASE 5.—Corporal K. was admitted to Ward A-1, November 14, with multiple small furuncles of both ankles. These

---

* Owing to lack of space, this article is abbreviated in THE JOURNAL by the omission of some of the case reports. The complete article appears in the reprints.

were dressed with dichloramin-T. December 13, they showed a positive cure for diphtheria. A dressing of tincture of iodin was applied daily. December 23, culture was negative and has remained negative. December 17, the Schick test was positive, and the patient was given 1,500 units of antitoxin.

Case 6.—Corporal C., admitted to Ward A-1, October 7, with a through-and-through gunshot wound of the left thigh, presented two large debrided wounds, one on the outer and one on the inner side of the thigh. Both showed a positive culture, December 13. The inner wound was treated with neutral solution of chlorinated soda (Dakin's solution) every two hours, and the outer wound with a wet dressing of 5 per cent. acetic acid. Both wounds remained positive until December 27, when the foregoing dressings were discontinued and the wound treated with tincture of iodin. Since then all cultures have been negative. The Schick test, December 17, was negative.

Case 8.—Private E. was admitted to Ward A-1, November 12 with a large wound of the left buttock which was treated by the Carrel-Dakin method. December 13, culture was positive, and the wound remained positive at each subsequent culture until January 31, *in spite of any type of treatment.* The wound was treated at first with Dakin's solution, and the patient received four doses of diphtheria antitoxin of 20,000 units each. Dakin's solution was discontinued and the wound dressed twice daily with undiluted diphtheria antitoxin. Since January 9, the wound has been dressed twice daily with tincture of iodin, and we were able to get our first negative culture, January 31. The wound, however, has remained "clean," and healing has progressed rapidly. The Schick test, December 17, was negative.

Case 11.—*Private B. was admitted to Ward A-1, October* 17, with a large debrided wound of the left thigh, which was treated with dichloramin-T. December 13, wound culture was positive. Dakin's solution was given a thorough trial; then 5 per cent. acetic acid as a wet dressing was used, and on December 31, the wound was cauterized with pure phenol neutralized in a few seconds with alcohol, but with negative results. January 2, tincture of iodin was used, and on the 6th we obtained a negative culture and the wound has remained negative with daily dressings of *tincture of iodin.* December 17, the Schick test was negative.

Case 15.—Private W. was admitted to Ward A-1, October 4, with a gunshot wound of the left foot, which was dressed daily with dichloramin-T until December 13, when culture showed positive. This was another very obstinate case and was complicated by a very marked dermatitis which had been caused either by the improper preparation or the improper application of the dichloramin-T. The wound was dressed daily with iodin, and with the exception of negative culture, January 9, remained positive until January 24. Cultures since then have been negative. The Schick test was positive.

Case 20.—Private B. was admitted to Ward A-1 from Ward A-2, December 17, with positive wound culture for diphtheria. The wound was treated with tincture of iodin, and on December 20, culture was negative. December 21, the Schick test was positive. Throat culture proved the patient a diphtheria carrier, and he was transferred to another hospital in the center for diphtheria carriers.

Case 29.—Private C. was admitted to Ward A-1 from Ward A-4, December 19, with a positive wound culture for diphtheria. This wound was covered with a dirty gray membrane, and diphtheria antitoxin was used; 20,000 units were given every forty-eight hours for four doses, with negative results. The wound was treated daily with tincture of iodin, and the first negative culture was obtained, December 31. All cultures since then have been negative. The Schick test was negative.

Case 33.—Private S. was admitted to Ward A-1 from Ward B-1, December 20, with a positive wound culture. This wound was covered with a thick gray membrane quite typical of diphtheria. Tincture of iodin was used daily until December 26 with negative results, when the patient developed clinical diphtheria and was transferred to an isolation ward in another unit. The Schick test was negative.

Case 43.—Private N. was admitted to Ward A-1 from Ward B-10, December 30, with a positive wound culture. The wound was covered with a typical diphtheritic membrane. It was cauterized with pure phenol neutralized in a few seconds with alcohol, but culture the following day showed positive. Diphtheria antitoxin undiluted was then used as a wet dressing twice daily, but with negative results up to January 24. The wound was then treated with tincture of iodin, and cultures the 28th and 31st have been negative. The Schick test was negative.

Case 46.—Private F. was admitted to Ward A-1 from Ward A-4, January 2, with a positive wound culture. Tincture of iodin was used daily, and on January 3 wound culture was negative; but a culture from the throat proved the patient to be a carrier, and he was transferred to another hospital for isolation.

Case 51.—Private D. was admitted to Ward A-1, October 16, with a gunshot wound of the hip. This was one of the original twenty "negative" cases left in Ward A-1 at the beginning of quarantine. All cultures up to January 6 were negative, but on this date the culture showed positive. Dakin's solution was discontinued and the wound treated with tincture *of iodin daily.* January 9, the culture was negative, and all subsequent cultures have been negative.

Case 60.—Private R. was admitted to our hospital, January 27, from another unit in the center. Wound culture on this date was positive for diphtheria. The patient was transferred to Ward A-1 from Ward B-2 and the wound dressed daily with tincture of iodin. January 31, culture was reported negative.

SUMMARY

1. In none of these wounds were there any systemic symptoms referable to diphtheria toxin. Most patients were well in every way and none showed any elevation of temperature other than what might well be explained by a large debrided wound.

2. The clinical appearance of the wounds varied. Twelve per cent. showed a gray membrane quite typical of diphtheria. About one half showed only a faint grayish discoloration of the granulating surfaces which under ordinary conditions would have passed unnoticed. About 6 per cent. looked absolutely healthy and ready for secondary closure.

3. So far as could be observed, the presence of diphtheria bacilli in the wound had no effect at all on wound healing. Wounds that were slow in healing invariably had large numbers of other organisms present. Wounds that appeared clean progressed in the ordinary way. And two wounds were positive up to the date of complete healing.

4. Forty-three patients received the Schick test. Six were positive. This is about the percentage for all adults.

5. The resistance to treatment varied greatly. In some cases diphtheria disappeared with two days' intensive treatment, while others were very resistant, as Cases 9, 15 and 43, which remained positive for forty-nine, forty-two and twenty-four days, respectively, in spite of all treatment.

6. By far the most efficient treatment has been the use of tincture of iodin. Under the most rigid asepsis the wound was cleaned with a 1 per cent. soap solution, ether and alcohol, and then painted with U. S. P. tincture of iodin, care being taken to protect the surrounding skin. Under this treatment the average duration of positive cultures was six days. Fifteen cases cleared up under forty-eight hours, and only eleven cases remained positive longer than one week.

Diphtheria antitoxin, up to four doses of 20,000 units each, was given in four cases, but had no effect in ridding the wounds of diphtheria. It was never necessary to give it for its systemic protection. Diphtheria antitoxin as a wet dressing was used in two cases, but without effect.

Acetic acid, suggested as a specific, was given a thorough trial in four cases, but was also of no value.

Two wounds cauterized for a few seconds with phenol were reported positive the next day.

The Carrel-Dakin method, applied very exactly in eight cases, was a failure in six. Two of the cases cleared up within forty-eight hours, but in my opinion they would have cleared up just as quickly under the iodin treatment. In the six failures the method was used over periods of from two to three weeks each, and these wounds cleared up very promptly after the Carrel-Dakin method had been discontinued and the iodin treatment instituted. Dakin's paste was not available. Dichloramin-T had previously caused so much skin irritation in the unit that its use had been discontinued by order.

II. BACTERIOLOGIC

By MAJOR MORRIS

Entering on the discussion of this series of wound diphtheria cases from the point of view of bacteriology, pathology and hygiene, let me first call attention to the fact that we are well aware that not all of our series were infected with virulent diphtheria organisms. Owing to a dearth of laboratory animals, however, it was not possible to test the offending organisms for virulence. One that we did test proved beyond the shadow of a doubt that it possessed virulence to a high degree. Our criterion in branding wounds as infected with diphtheria bacilli was based purely on cultural methods, with the resulting study of the morphologic characteristics, and to some extent the biologic. We also realize the fact that a wound might contain diphtheria bacilli and yet not necessarily be a case of wound diphtheria, any more than diphtheria bacilli found in a clinically normal throat make that a case of throat diphtheria; yet as we consider the latter a "throat carrier," so must we consider the former "wound carriers."

We called diphtheria bacilli only such organisms as showed the typical morphologic characteristics, that is, those which showed when grown for from eighteen to twenty-four hours on Loeffler's blood serum medium as slender rods of practically uniform thickness except for the "clubbing" at both extremities. The stain used was Loeffler's alkaline methylene blue, and microscopically it showed the organisms taking a blue stain throughout except at the extremities. The bodies either appeared granular (fine) or had the striped appearance so often noted. The "clubbed" ends took on a more violaceous hue and were homogeneous. Some showed a central swelling.

Let me add the following data in proof of virulence: As is noted above in this paper, from Oct. 14 to Nov. 16, 1918, six clinical throat diphtheria cases and five carriers were discovered in Ward A-1. During December, 1918, five more true throat diphtherias and four more throat carriers were found in this ward. Up to this time, or rather up to Dec. 13, 1918, we followed the routine prophylactic course for eradicating diphtheria in the hospital by repeated throat cultures for the detection of carriers, and it was always an easy matter to find a carrier in this ward for reasons that will soon become apparent. Yet the incidence of throat infection continued unabated, despite repeated culturing, quarantine, etc. The futility of the methods used is what prompted us to seek the cause elsewhere than in the throat. Accordingly, Dec. 13, 1918, all of the wounds in Ward A-1 were cultured on ordinary Loeffler's blood serum medium. Twenty-eight positive wounds were found, some of the patients having two or three positive wounds.

The following steps were at once taken: 1. Absolute quarantine of the ward was established, and by this is meant that no one was allowed to leave the ward except the ward surgeon and the nurses. Even the enlisted personnel employed in the ward were sequestered there. Food, clothing, etc., were brought to the door of the ward and left there. 2. Blankets, mattresses, pillows, bedclothing, etc., were all thoroughly sterilized, for here were materials that were undoubtedly harboring billions of the provoking organisms after coming into such intimate contact with badly infected dressings. From these infected bedclothes, etc., the organisms were carried far and wide by the hands and clothes of the patients, attendants and others. 3. Routine cultures of wounds and throats were taken both in this and in the other wards. 4. Schick tests were performed in this and other wards, but the value gained from this source was negligible. 5. Extra precautions as regards sterility of dressing instruments and dressings were taken.

Soon after the foregoing precautions were taken, the incidence of throat diphtheria fell. From Dec. 13, 1918, to Jan. 1, 1919, the record of throat diphtheria in Ward A-1 was two cases, one coming to light, Dec. 21, 1918, and the other six days later. Between Jan. 1 and Feb. 1, 1919, no cases of throat diphtheria developed in that ward, and the incidence of diphtheria throughout the entire hospital during that month was practically nil.

AN EPIDEMIC OF BRONCHOPNEUMONIA

ROENTGENOLOGIC STUDY

FREDERICK E. DIEMER, M.D. (HOT SPRINGS, ARK.)
Captain, M. C., U. S. Army
CAMP LEWIS, AMERICAN LAKE, WASH.

During the recent epidemic of respiratory infection at this cantonment, arrangements were made to examine by screen or plate all cases of so-called influenza that were admitted to the base hospital. These examinations were undertaken because of the detection of many cases of mild bronchopneumonia during the routine examination of the chests of the draftees, of whom about 23,000 have been fluoroscopically studied for the tuberculosis board of Camp Lewis. In this study, many cases of bronchopneumonia of one or both bases were discovered. Each case was examined carefully, and each patient stated that he had been suffering with a cold for several days. Verification of the diagnosis of bronchopneumonia was obtained clinically.

So much assistance was afforded the clinician, that after a few weeks at the suggestion of Capt. Charles A. Ballard, all patients except those distinctly pneumonic were admitted to the observation ward and roentgenographed before being distributed to the different pneumonia wards. Those admitted in the evening were sent to the roentgen-ray laboratory the next day at 11 a. m. Those only slightly ill were screened, while those more seriously ill were plated. The fluoroscopic reports were immediately returned to the observation ward. The plates were developed at once and the report was furnished in about one hour. The patients were then distributed to the various wards.

In the neighborhood of 7,000 influenza patients were subjected to roentgenographic examination. Those able to walk were screened but ill patients were ught to the roentgen-ray laboratory, well wrapped, the hospital litter carts, and were placed on the able face down, without being allowed the least exertion. A stereoscopic set was made, for the most part gas tubes being used because they produce a plate of better detail and more contrast than does the Coolidge. Although the work proved to be more wholesale than delicate, we strived to obtain the most perfect plate, and our plates were surprisingly uniform, possessing excellent detail. The desperately ill patients were examined in the ward by means of the portable bedside unit. Exposure was made on the thin double coated film between two block screens.

Bronchopneumonia was found in some 2,200 cases. By far the larger percentage (about 80) was an involvement of one or both bases. All degrees of involvement in all combinations were found. The lobe involvements were classed as mild, moderate or severe in the different lobes. The parenchymal involvement we tabulated as:

1. Peribronchial, only the air sacs adjacent to the bronchioles being involved (capillary bronchitis?).
2. Central, apparently beginning at the hilum and extending bronchogenetically toward the periphery.
3. Confluent, involving an entire lobe and presenting a picture suggestive of lobar pneumonia.
4. Lobular, which distinctly involved the lobules.
5. Diffused, presenting one or more of the foregoing in an entire lobe, an entire lung or both lungs.

We were often able to suggest bronchopneumonia before clinical findings were obtained. This was especially true in those cases in which the involved area was small and centrally located in the body of the lobe, particularly the lower. Again, our findings were often indefinite when the clinical indications were pronounced. This occurred in those cases in which the process was posteriorly situated, especially as the area was far removed from the plate (the patient lying face down). In the very mild parenchymal involvement occuring in the capillary bronchitis, the plate showed definite indications while physical findings were minimal. Medium and coarse râles were heard, but the finer ones were not made out, especially if centrally located, until the process became more advanced. It usually did so in a few hours, and the most painstaking physical examination was necessary in many cases before the delicate change in breath sounds, the slight dulness and the finer râles of bronchopneumonia were detected.

A great many cases were examined a number of times and the process was watched, as it insidiously advanced from the small primary area to a very extensive involvement of both lungs. Every possible complication was found and studied.

In addition to the exact involvement of the lungs, we made careful observations of the heart silhouette, and its area, position and configuration. Each patient's weight, age and height was reported on the request for roentgenographic examination. The heart condition was reported, allowing for a reasonable increase or decrease in area from the average. Cardiac stimulants were often suggested to the ward surgeon because of marked increase in the cardiac silhouette area with increase in radiability, as is the case in dilatation.

Five cases presented shadows indicative of a chronic tuberculous process in addition to the bronchopneumonia. The tuberculous process presents entirely different shadows than does the bronchopneumonia. This is very obvious when both processes are seen on one plate. Streptococcus bronchopneumonia is difficult to differentiate from an active fibrous tuberculosis, particularly during the resolving stage.

In many cases showing distinct shadows indicative of bronchopneumonia, the physical findings were absolutely negative, except for bronchitis. Our findings were so pronounced that we carefully investigated these cases and determined the areas of density resulting from parenchymal exudation. These cases subsequently presented the physical findings of mild bronchopneumonia. At necropsy, about 10 per cent. of the bronchopneumonia patients had one or more areas of parenchymal hemorrhage in addition to the areas of consolidation. This suggests that probably in some cases hemorrhage into the lung tissue was the beginning of the bronchopneumonic process.

After resolution is complete, abnormal shadows persist for some time. This is particularly true in the lower quadrants, where the trunks are large. It is, however, not difficult to distinguish an active from a resolved process. In many cases the streaks of air along the course of the blood vessels (emphysematous air streaks) are distinctly seen, and although they occur in all stages of the process, they are suggestive, for the most part, of beginning resolution. The air streaks are apparently the result of air sac rupture following increased distal pressure from impingement on the bronchiole. The air released into the interstitial tissues follows along the vessels as the path of least resistance. These air streaks are often readily made out as scalloped dark streaks leading toward the hilum.

For detecting mild processes and determining the extent of the involvement, the roentgen ray is an ideal means, and should be employed in every case of respiratory infection, both in civil and in military hospitals.

Roentgenographic findings are definite in bronchopneumonia and enable the clinicians to appreciate the extent of parenchymal involvement. The degree of involvement in bronchopneumonia should receive a more careful consideration. Many cases of "colds" and bronchitis present a mild degree of bronchopneumonia.

Direct Prophylaxis of Rabies.—All the dogs in the Kanagawa district, Japan, were inoculated last year against rabies, a total of 6,644 dogs. This region is said to include two cities and six districts. During the year there were twenty cases of rabies among the dogs in September, three in November and none in December. The preceding years the incidence of rabies reached its highest point in December. The *Japan Medical World*, which reports these facts, gives the details of Umeno's method of preparing the antirabic vaccine for the purpose, and its applications in the research described by Drs. T. Kitano and K. Sukegawa, sanitary officers of the Kanawaga prefecture, Yokohama. A single inoculation apparently answered the purpose; half the dose was injected on each side of the dog. No by-effects were observed of any moment,-merely an occasional transient local swelling.

A REPORT OF DIPHTHERIA AT CAMP CUSTER, MICHIGAN

FROM SEPTEMBER, 1917, TO MARCH, 1919

WYNDHAM B. BLANTON, M.D. (Richmond, Va.)
Captain, M. C., U. S. Army; Chief Laboratory Service
AND
CHARLES W. BURHANS, M.D. (Cleveland)
Captain, M. C., U. S. Army
CAMP CUSTER, BATTLE CREEK, MICH.

At the beginning of the present war it was not altogether certain what effect the grouping of large bodies of men under military conditions would have on the incidence of diphtheria and the prevalence of diphtheria carriers. The mobilization and training during the last eighteen months of some 113,000 men at this camp has afforded an opportunity to observe locally such facts about diphtheria.

CASES OF DIPHTHERIA

From September, 1917, to March, 1919, a total of fifty-seven cases of diphtheria were admitted to the base hospital. Most cases ran extremely mild courses. Six days was the average length of time for the membrane to remain in the throat. Complications were rare. Two cases of paralysis and one of myocarditis resulted.

SUMMARY OF LABORATORY WORK ON DIPHTHERIA

Examinations for	Total Number	Found		Incidence in Hospital Attendants
		Number	Per Cent.	
Cases of diphtheria............	.....	58	....	5
Carriers of diphtheria..........	8,236	148	1.8	25
Nonimmunes (Schick test)......	7,851	808	10.3	

One death occurred as a result of streptococcic septicemia intervening after the diphtheria was clinically ended. The localization of the exudates was as follows: tonsils, 41; pharynx, 4; pharynx and tonsil, 10; pharynx and larynx, 1; nose, 1. The average white blood count was 15,000. Six cases showed albumin, and three, casts in the urine.

About 90 per cent. of the organisms isolated showed bipolar granules. Virulence tests were made by subcutaneous injection of guinea-pigs with pure cultures of the isolated organism. Of twelve organisms so tested, five proved to be avirulent. Too much reliance is probably placed on the so-called "virulence test" for diphtheria. McCord[1] points out the possibility of variation in virulence of diphtheria strains, and Meader[2] has shown in a number of strains that marked variations occur for the same organism in subcultures in morphology, fermentation reaction and virulence.

Diphtheria in this camp has been purely a sporadic disease, evidencing none of the epidemic characteristics sometimes attributed to it. The average incidence has been 2.6 cases a month, or a little less than 0.2 per cent. of the total admissions to the base hospital. Diphtheria has not been confined to any small group of organizations or to any geographic location of the camp. On the contrary, the cases have been widely distributed. Fifty different organizations are represented in the total of fifty-seven cases admitted to the base hospital. In those instances in which more than one case of diphtheria has occurred in one organization, more than thirty days have elapsed between cases. Only one organization has had as many as three cases of diphtheria. The season of the year has apparently made no difference. In January and June, 1918, there were six cases each. In September of the same year there were seven.

CARRIERS

A great deal of care has always been exercised in the search for carriers of diphtheria. For the greater part of the time it has been a routine procedure on finding a case of diphtheria to quarantine the company to which the patient was attached until two throat cultures taken at two-day intervals could be made, and Schick tests done and read. Thus, cultures have been taken of 8,236 persons. In more than half of the instances, these were taken a second time, making a total of 13,000 cultures. In all, 148 carriers were found. This was 1.8 per cent. of the number of persons examined. The diagnosis has in all cases been purely a morphologic one.

The solid-body type of organism has been most frequently found, but those showing polar bodies have also been encountered in a considerable number of instances. Twenty-four strains recovered from these cultures were inoculated into guinea-pigs. Of these, 88 per cent. proved to be avirulent.

The occurrence of carriers in different camp organizations was relatively large in only a few instances. In one company fourteen were found, in another ten, in another seven, and in two others, six each. Twenty-five carriers have been found among the base hospital personnel. Five of these were nurses or attendants in the diphtheria wards. With the above-mentioned exceptions, the average company has furnished a little more than two carriers of diphtheria. That many of the carriers are transient hosts for the diphtheria bacillus is shown in the rapid disappearance of organisms, in most cases, after entering the hospital. This was particularly true of the organizations showing a relatively high incidence of carriers. A number of these were doubtless case contacts.

In the case of chronic carriers, to rid the throat of diphtheria bacilli often required the greatest patience and persistence. The variety of methods employed indicates the inefficacy of most of them. Sprays of dichloramin-T, Dobell's solution, neutral solution of chlorinated soda (Dakin's solution), argyrol and finally a solution of antitoxin (5,000 units to 30 c.c. of water) gave place to one another as hope in a new procedure gained force in face of failure with an old. It seemed hardly possible to reach organisms like diphtheria bacilli with sprays, however bactericidal, buried as they often are in the tonsillar crypts. On numerous occasions it has been our experience after two negative cultures to make a culture from the depths of the crypts and find the organism.

Patients and carriers were discharged after three negative cultures. A number of these were instructed to return to the laboratory after two weeks for another culture. With one exception there were no cases in which we were able again to identify the diphtheria bacillus.

Striking results have been obtained after tonsillectomy. One patient, in spite of the most vigorous throat spraying, presented diphtheria bacilli continuously in his throat in forty-eight consecutive cultures. Tonsillectomy was done. The next three cultures were negative. Three other tonsillectomies were equally successful in patients that had presented diphtheria bacilli in their throats for forty, fifty-four and forty-six days, respectively.

[1] McCord, C. P.; Friedlander, A., and Walker, R. C.: Diphtheria and Diphtheria Carriers in Army Camps, J. A. M. A. **71**: 275 (July 27) 1918.

[2] Meader, P. D.: Variation in the Diphtheria Group, J. Infect. Dis. **24**: 145 (Feb.) 1919.

Of the cases of diphtheria in the hospital, forty-eight showed 1,100 days of positive cultures, a case average of 20.9 days. Twenty-two of this number averaged much higher—from twenty-five to fifty-eight days.

Of the carriers, on the other hand, 121 had 1,421 days of positive cultures, averaging 11.7 days per case. However, many of the cases of diphtheria gave negative cultures before the expiration of two weeks, and those in which diphtheria bacilli were found after this period should be classed, for the most part, as chronic carriers.

SCHICK TESTS

Schick tests have been made at the time of culture of all persons exposed to diphtheria. In all, 7,851 have been done and 10.3 per cent. have been read as positive. This is about the recognized average incidence among naturally unprotected persons between 21 and 31 years. The usual technic in giving the test has been observed. Injections of diphtheria toxin were carefully made intracutaneously. Controls consisted of diphtheria toxin heated to 75 C. for five minutes. Readings were made at the end of forty-eight and ninety-six hours. The delayed reading was used to minimize the error from pseudoreactions.

It has been the custom to give 500 units of antitoxin prophylactically to all naturally unprotected individuals recently in contact with diphtheria. The opinion prevailed that the temporary protection afforded the susceptible individual more than compensated for the small danger of sensitization against horse serum, especially as desensitization before serum administration is now a generally recognized precautionary measure. The use of toxin-antitoxin mixture has not seemed practical on account of the time consumed in securing immunity by such a method.

SUMMARY

1. Diphtheria has not been a very prevalent disease at this camp. Of 113,000 soldiers trained here during a period of eighteen months, only fifty-seven developed this disease.
2. Of 8,236 throats of which cultures were taken, 1.8 per cent. were found to be carriers of diphtheria bacilli.
3. Of 7,851 Schick tests done, 10.3 per cent. were positive.
4. Tonsillectomy is the final and only satisfactory method of disposing of chronic diphtheria carriers.

Illiteracy Among Working Children.—The National Children's Bureau announces that in the five states where federal certificates of age are required for children going to work, among 19,546 children between 14 and 16 years of age, 5,294, or more than one fourth, could not sign their names legibly. In the five states, among 18,379 white children between the ages of 14 and 16, only 742 of them had reached the eighth grade in school; of 1,166 colored children to whom certicates were issued, only forty had reached the eighth grade. This means that 96 per cent. of white children and 97 per cent. of colored children granted certificates had not reached the eighth grade in school. In some states a work permit cannot be secured until the age of 16 unless the child has completed the eighth grade. Only 248, or 1.3 per cent., of the children certified by the Children's Bureau could have met such a requirement.

PHYSIOLOGY OF RESPIRATION IN TREATMENT OF WAR WOUNDS OF CHEST AND EMPYEMA

JOHN R. GREEN, M.D. (Independence, Mo.)
Captain, M. C., U. S. Army
KANSAS CITY, MO.

Empyema is essentially a condition in which the normal physiologic processes of the lung and pleura on the affected side or sides are altered, impaired or suspended. These are replaced in part by defensive processes, namely, the emigration of leukocytes in response to the presence of pathogenic bacteria or foreign bodies; the outflow of lymph to dilute toxins and to fill spaces that were potential spaces only, in the normal organ; an increase in the blood vessels for nourishment and repair of the affected part; and round-cell infiltration to establish a direct barrier to the advance of bacterial infection and an indirect barrier to the spread of infection by immobilizing the motor mechanism through plugging its cellular spaces and lymphatic channels. This, in fact, is an inflammatory process with exactly the same characteristics as an inflammatory process in any other part of the body. Therefore, any plan for the treatment of the disease must be based on a careful consideration of the physiologic and pathologic problems involved, exactly as is done in the treatment of inflammation elsewhere.

An apparent disregard or misunderstanding of the true physiology and pathology is responsible for the disastrous high mortality mark of 84 per cent. in one army camp and an average mortality rate of 30.2 per cent. in all army camps, as was determined by the questionnaire of Feb. 21, 1918 (Empyema Commission report).[1] This unfortunate picture is further contributed to by the following statement from one camp:

> Convalescence is more than three months in duration in all cases, and not one has been found with full restoration to health. Of those finally released from the hospital, eight have been readmitted with recurrences, and not one has been able to resume a full duty status; it is very doubtful if any of these patients will become fit for the full performance of duty as a soldier within six months after operation, and the majority undoubtedly never will.

These statistics and this statement are from men of great ability as surgeons. It does not include the vast number outside the army who undertake the treatment of empyema because they are able to resect a rib, that being the sum total of the obligation on the part of the operator in many cases. Statistics are not published in any of these cases.

The best surgeons, the men who take into their wor the best known physiologic and pathologic treaching rely on these principles to obtain results: That th lungs which are inclosed in the thoracic cavity an entirely shut off from the pressure of the air fron without are pressed on from within by a force o approximately 15 pounds to the square inch. Th weight of the air, therefore, literally blows the lung out to fill the interior of the chest cavity. The interna capacity of the chest is increased by the contractio of the diaphragm acting as a piston moving downwar and by the contraction of the levator costarum and th external intercostal muscles pulling upward on th ribs. The weight of the air constantly exerting its force to press the lungs against the parietal pleura is known as the intrathoracic pressure and is equal to the intrapulmonic pressure minus the elastic recoil of the lungs. Also expiration, according to this theory, is due to a diminution in the size of the thorax through the relaxation of the diaphragm and the contraction of the internal intercostals, the triangularis sterni, and the transverse thoracic muscles, pulling the ribs downward, together with the elastic recoil of the lungs, there being, also, accessory muscles causing accessory respiratory movements. This commonly accepted mechanical view of respiration, which assumes that respiration is largely a passive act, should be examined in the light of clinical facts observed in the treatment of war wounds of the chest, in the treatment of empyema cases, and in connection with physical phenomena always considered unexplainable on this theory. These clinical facts should be suggestive for further experimental work.

CLINICAL OBSERVATIONS IN WAR WOUNDS OF THE CHEST

Pierre Duval,[2] chief of all the French lung and chest surgeons, whose experience was obtained at the Somme and in many later campaigns, says that surgery of the lung is a revolution. "Dread of pneumothorax had hitherto entirely limited the field of lung surgery, but the surgery of the war has triumphantly proved the value of the old and essentially French method of inducing pneumothorax." A large thoracotomy opening is made and the lung is withdrawn and operated on just as a coil of intestine is withdrawn from the abdomen. This method is a common practice of Moynihan[3] and all the surgeons of the Allied armies when fresh wounds of the chest require treatment. Lungs operated on in this way soon resume their normal function when replaced, and the chest is closed, whether or not the air is aspirated from the chest.

In chest wounds of moderate size it is a very common occurrence to find a part of a lobe of the lung bulging out of the wound plugging the opening in the chest wall. J. K. Murphy,[4] one of the leading British surgeons, says: "Traumatic hernia of the lung may occur immediately through free openings of the thorax." Van Reeth and Vouchen, Belgian surgeons, report a case of strangulated pulmonary hernia, and they express the opinion that this condition probably appears much oftener than is recognized.

The observation of the collapse of the lung, either massive or of one or two lobes, has frequently been made. Pasteur[5] was the first to report this as due to the reflex inhibition of the diaphragm which he had observed following an abdominal operation in which the diaphragm was not injured in any way. Crymble[6] reports fifteen cases of massive collapse of the lung. These fifteen cases were due to gunshot wounds of the chest. Ten of the collapsed lungs were on the side opposite to that of the injury. Rees and Hughes[7] report a series of 140 cases of gunshot wounds of the chest. These authors state that collapse of the lung is very frequent, as it is Nature's most potent method of arresting hemorrhage. They observe, also, that it is fairly common on the side not wounded. "It is of the utmost importance to grasp the fact," says Duval, "that not only does the actual wound affect the lobe traversed, but the other lobes of the same lung may sustain partial injury, and the opposite lung may, by contracoup, be more or less seriously injured." He describes these injuries as occurring usually about the hilum and as extensive contusions with hemorrhagic infiltrations.

It is interesting to note that Landis[8] reports cases from civil practice in which collapse of the lung occurring spontaneously is almost invariably on the right side, and that most of the cases of reflex collapse of the lung from trauma in war surgery occur on the left side.

A very fundamental principle established in war surgery of the lung is the terrible fatality of wounds of the diaphragm. The patient with a lung wound has an excellent chance for recovery. He may recover with a wound of a hollow viscus even if it is not sutured. But, to quote Lockwood and Nixon,[9] "as early as the middle of July, 1916, it was realized that practically all wounds of the diaphragm left unrepaired proved fatal."

CLINICAL OBSERVATIONS IN EMPYEMA CASES

That the diaphragm is motionless on the affected side, that it has lost its arch, that it is either quite flat or arched slightly downward is a common and universal observation in empyema. In the cases under treatment in the base hospital at Camp Upton, after several days during which the entire empyema cavity had been irrigated freely and thoroughly by several quarts daily of hypertonic solution according to the formula of Thiersch, and the treatment which was first recommended to this hospital by Major Delatour, I have been remarkably impressed with the occurrence of a very sudden change in the condition of the organs. Between the times of treatment the diaphragm has assumed an upward arch, either partly or wholly obscuring the view of the cavity. It has become contractile and very irritable to pressure or touch. The lung has now for the first time expanded, so that the cavity is almost completely filled. An approximate measurement of this is taken, incidentally, all the time by the fact that the cavity holds a quantity of the irrigating solution which almost fills a large pus basin. On the morning that the lung and the diaphragm have become active, only an ounce or two of the solution is required to fill the cavity. This condition exists for from two days to about one week in acute cases in which the time for operation has been properly chosen and in which the drain has been properly placed and is of sufficient size. The drainage tubes, which from the start have been of a length just adequate to hold the chest wall apart and not to project inside, are removed because they irritate the diaphragm and are an interference to the lung expansion. No attempt is made to close the wound in any case, with the rare exception when the muscle mass, chiefly the latissimus dorsi, gapes widely and it appears that the function of this muscle will be restored more quickly by uniting its cut ends and the skin over it. But the lung and the diaphragm are now thoroughly adapted to the presence of the air, with its varying temperature, and the blood within the lung reduced in quantity, since both lung and diaphragm are protected by a thick, edematous wall consisting of folds of pleura and underlying cellular tissue with abundant supply of lymph vessels; the lung continues to expand down to the open wound in the wall of the thorax (Fig. 1).

Others have noted this heretofore unsuspected sudden recurrence of lung expansion. I quote from the report of the Empyema Commission[1] at Camp Lee: "It has been surprising in several cases to note the remarkable speed with which the cavity has diminished in size or has become obliterated after sterility has been accomplished with Dakin's solution." Homans,[10] reporting a series of cases from the Peter Bent Brigham Hospital, says: "If one follows the healing of an acute empyema both clinically and in a series of stereoscopic plates, one is able to appreciate the steady and apparently resistless effect of these four favorable influences." Among these "favorable influences," he mentions the rise of the diaphragm as being always noteworthy.

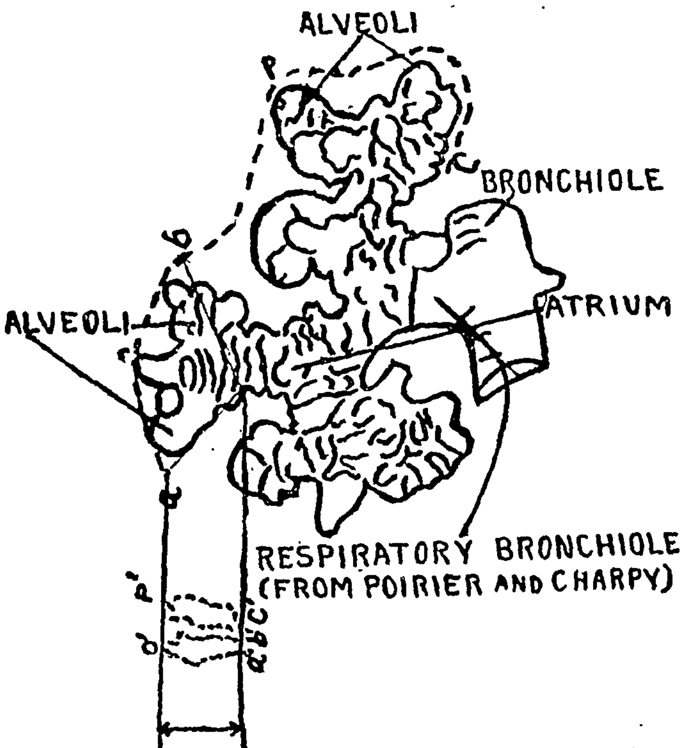

Fig. 1.—Folding of pleura increasing thickness of wall when alveolus is collapsed (copied from Gray's Anatomy). Line *a o b*, representing the pleura, is folded on itself, increasing the thickness of the pleural wall *a' o' b'* as represented in the space indicated by the arrow.

A condition of vast importance in the study of lung expansion is that of double empyema. Last winter I treated two cases of this rare affection:

Case 1.—R. D., aged 19, developed an empyema two weeks after an operation for general peritonitis from ruptured gangrenous appendix. His condition was so bad during the first week of the peritonitis that hypodermoclysis was used very often over every part of both sides of the chest and flanks. His right-sided empyema occurred, whereupon it was drained under a general anesthetic. He did well for several days until he developed dyspnea and fever, and an empyema was discovered on the opposite side. We tried for several days to aspirate the pus from the unopened thorax, but it was a mixed infection of *Streptococcus hemolyticus* and *Bacillus coli*, which produced a thick, flaky pus, rendering our attempts to remove the pus by this means unsuccessful. In spite of all our fears of double pneumothorax, the chest had to be drained, because the patient was gradually but certainly losing ground. All available preparation was made to use suction apparatus in the chest wound; and a lung motor was at hand if necessity should require it. Thoracotomy, under local anesthesia, through a subperiosteal resection of the ninth rib was done, and a drainage tube with a large flange on the pleural and also on the skin side of the thoracic wall secured in the wound without air entering the pleural cavity. The ease with which this is done in the presence of a positive pressure of purulent exudate is the best proof that such a device is quite unnecessary. Respiration was not the least embarrassed but the patient was relieved, and he continued to improve with both pleural cavities open. The double empyema was cured in about two months by simple adequate drainage and without antiseptics of any kind.

Case 2.—F. L., a boy, aged 7, presented a double pyothorax following pneumonia. The entire chest was so crowded by the fluid that it had assumed an extremely rounded shape. About a pint of thick, yellow pus was drawn from both the right and the left side of the chest the first day. This was done through a large trocar and cannula. A soft rubber catheter was slipped through the cannula and the cannula was withdrawn, leaving the catheter in place. The catheter on the right side was allowed to remain open for continuous drainage. A knot was tied in the catheter on the left side because it was feared that air might enter both sides of the chest at once with perhaps very serious results. In about a week the right thorax was opened through a subperiosteal resection of the ninth rib in the scapular line, and adequate drainage was established. Several days later an attempt was made to treat the left side in a similar manner. The roentgenogram showed a dense shadow at the level of the seventh intercostal space and below this point. It was in this space in the scapular line that the catheter had been placed. The resection of the eighth rib proved to be at the lower side of the diaphragm, but not in the peritoneal cavity. The wound was packed with antiseptic gauze and a secondary suture done in a few days, the wound in the meantime being carefully guarded against further contamination. The drainage continued through the small catheter on the left side, and both sides healed in about three months.

In each of these cases of double empyema, a double pneumothorax was established.. It may be supposed that the main pleural cavity was walled off. In the first case cited, either side could be examined with a probe and a space felt between the partially collapsed lung and the diaphragm. The second case proved to have no negative pressure in the chest, but there was a positive pressure sufficient to force pus out through catheters simultaneously from the two thoracic cavities without any suction whatever during the first treatment.

GENERALIZATIONS FROM CLINICAL EVIDENCE IN WAR WOUNDS OF THE CHEST AND IN EMPYEMA

It is more than evident that the theory of respiration which assumes that the lung is merely a passive organ in the process of expansion is inadequate to explain any of the clinical evidence that has been cited. Although negative pressure is, without doubt, one factor in the production of lung expansion in normal life, it is equally certain that the principal force in the production of lung expansion must lie in the automatic expansile power of the lung itself.

Clinical evidence supports the following generalizations:

1. Respiration is reestablished in a collapsed lung only when the movements of the diaphragm are established as rhythmic contractions.
2. The lung expands itself and forces itself into an open, large wound of the chest wall, not seldom and

---

10. Homans, John: The Prognosis and Treatment of Empyema, Ann. Surg. 67: 697 (June) 1918.

accidentally, but very often and always in the presence of full atmospheric pressure opposing the protrusion toward the opening in the chest wall, and with the root of the lung pushed further laterally than normal from the open thorax wound.

3. The diaphragm is vital in the production of the respiratory reflex because wounds of the diaphragm if unrepaired always produce death even though the muscle is situated so that its contraction will make an air-tight and water-tight valve which would insure a perfect piston action. The cause must lie in a disruption of its coordinating mechanism similar to fibrillation in the heart muscle.

With this evidence from war wounds of the chest and from the behavior of the lung in recovering from empyema, we have been able to read the process backward and to make the statement that probably every case of empyema is preceded by a collapsed lung to some degree, because the lung always remains in a collapsed state until the diaphragm contracts, the contraction always initiating the respiratory cycle. Therefore, collapse of the lung due to immobilization of the diaphragm from reflex causes, such as an inflamed pleura or a plugged bronchus, and very often plus a lowered threshold of irritability from fatigue or the exhaustion of infection, is the first stage of empyema. The second stage is the pouring out of exudate to fill the dead space about the lung because a living animal organism never tolerates a dead space. This exudate is rapidly loaded with pathogenic bacteria which are present in the lungs and in the pleura before this climax was reached in the demand for physiologic rest. The leukocytes wander out in response to the stimulus of the presence of bacteria, marking the third stage in empyema. Empyema, up to this point, is a defensive process.

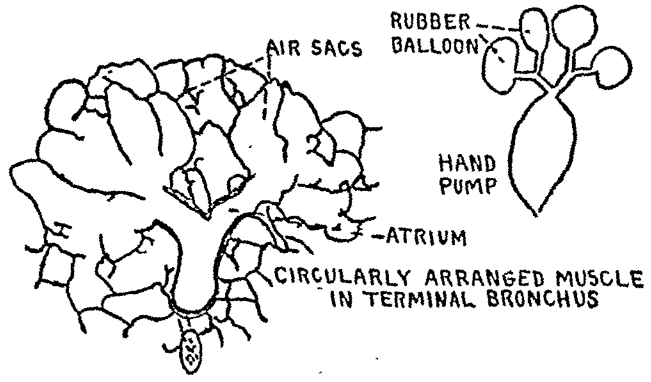

Fig. 2.—Camera lucida tracing of a 2½ year old child's lung (Miller in Bailey's Histology): heavy line, smooth muscle.

I have been delighted to find that the best kind of direct evidence has already been published supporting this conclusion which was derived from circumstantial evidence in the clinical facts already cited. Barjon,[11] chief roentgenologist of the Yale University School of Medicine, who saw this process occur under the fluoroscope, and who also recorded it with roentgenograms, thus describes it:

> It can be shown that paralysis of the diaphragm precedes effusion and that it survives its disappearance. . . . A patient was admitted to the service with a severe stitch in the side which had just appeared during the day. He was radiographed immediately and there was shown on the diseased side a very clear hemothorax; the contour of the diaphragm and the lateral culdesac were perfectly intact and there was no trace of fluid in the pleura. But the diaphragm was completely immobilized and no respiratory movement was seen, while on the opposite side it was very extensive. The next day another examination showed that the effusion was produced in the interval and that it occupied already half the hemothorax. Immobilization of the diaphragm, therefore, precedes effusion; only it is rarely that this fact can be observed, the patients ordinarily being seen only when the effusion is established.

Barjon tells us that the movements of the diaphragm do not cease in hydrothorax from Bright's disease, but that they are retained in spite of the existence of an abundant effusion. It is apparent, therefore, that there is a fourth stage in the development of empyema consisting in the invasion of the diaphragm by micro-organisms from the exudate which continues as long as they are present in the organs above. The presence of virulent bacteria in the lymphatics and the cellular spaces of the diaphragm is a stimulus for an infiltration with lymphocytes and leukocytes, thus permanently sealing and immobilizing it as long as the infection reaches it from the parts adjacent and above. This fourth stage in the development of empyema is also a defensive process.

Early operation in empyema following bronchopneumonia in which the pneumonic process has not subsided is a damaging violation of these natural defensive reactions. The diaphragm is freed from its inflammatory processes, and perhaps in a partially recovered state is stimulated to action by an open pneumothorax, with the inevitable extremes of temperature of air reaching it, as well as from physical and chemical trauma. The one case in our service in the base hospital that came to necropsy illustrates this point. At the time of operation there was a considerable amount of thin, flaky, deeply cloudy exudate about a large, boggy, resistant lung. Convalescence after operation was slow, but the temperature dropped to normal in the course of about ten days and the patient walked about the ward and felt fairly well. The pus from the empyema cavity diminished in amount, and the cavity became smaller by about one half. Suddenly one evening, the patient collapsed and developed a high temperature and rapid pulse. The next day the lung was found to be collapsed considerably more than it had been the few days just preceding the new disaster that had come to him. During the following ten days, this patient developed a general septicemia of hemolyzing streptococcus, endocarditis, glomerular nephritis, and hemorrhages into the meninges. All of these complications were probably due to the rupture of a lung abscess into the blood stream, the postmortem examination of the lung showing several small, unruptured pulmonary abscesses.

The treatment for a case like this suggests itself. The pneumonia should be treated until it has completely subsided without any meddlesome thoracentesis and until the roentgen-ray studies show that the case is ready for definite, radical surgical treatment. Thoracentesis should be done only as a final safeguard to check [illegible] diagnosis. Reports by Major [illegible] hers make it certain that thoracentesis is by no means a harmless procedure. "In explanation of the foregoing order," he says, "it should be emphasized that exploratory tappings and the use of the Potain treatment is not without danger." He mentions one death from exploratory tapping, a number of cases of collapse, and several patients showing bad effects a few hours afterward. The diagnosis having been made both as to the presence of the disease and also as to the stage, which is equally important, the pleural cavity should be drained in a very thorough manner. If the condition of the lung is suggestive of unresolved pneumonia or pulmonary abscess, which cannot be safely evacuated, the lung should be immobilized and not encouraged to expand. Formerly, my idea in every case of empyema was to help the lung to expand by direct exercises causing active respiratory movements. Now, I am convinced that every lung will expand as soon as the lung and its timing-gear, the diaphragm, are in a healthy condition, and sometimes when only the diaphragm is in a fit condition to function. If the disease of these organs is eradicated, there is no fear of the condition becoming chronic, whether there is open pneumothorax or not.

[12] Hamburger, W. W., and Myers, L. H.: Pneumonia and Empyema at Camp Zachary Taylor, Ky., J. A. M. A. 70:915 (March 30) 1918.

The method of empyema treatment described by Morelli,[13] and by Bastianelli,[14] is well calculated to accomplish this result. The principle is to free the thoracic cavity of pus, either by good open drainage with the thoracotomy opening stoppered by inflated rubber bags, or by a closed thorax and large needles to aspirate the pus and cleanse with antiseptics. In each case, a positive pressure is maintained for from five to fifteen days or even longer. This idea of immobilizing the acutely diseased lung and pleura is merely an extension of the Forlanini method in the treatment of tuberculosis. It is needless to say that Forlanini's method is one of the real hopeful developments in the treatment of otherwise hopeless cases of tuberculosis, which is evidenced by the fact that as far back as 1913 over 1,000 cases of advanced pulmonary tuberculosis were reported with 40 per cent. symptomatic cures.[15] Now hundreds of cases are reported every year with very encouraging results, showing that a diseased lung recovers more quickly and more certainly if given physiologic rest, so admirably insisted on by Crile[16] as a basic principle in the treatment of infected and traumatic wounds of war.

One of the closed methods of the treatment of empyema, in which the pressure of the infectious bacteria-laden exudate is replaced every two hours with a cold neutral solution of chlorinated soda (Dakin's solution), secures physiologic rest of the lung with very gratifying results in some of the very early cases of the disease in which the bronchopneumonia has not subsided. The effect of the cold is well shown in recent experiments which we have carried out in relation to the cause of expansion and collapse of the lung.

ANIMAL EXPERIMENTATION AS TO THE CAUSE OF LUNG EXPANSION

Dogs were used. The work was done under local anesthesia, with morphin to keep the animal quiet and to diminish shock. Our patients operated on with a local anesthetic were not shocked or made worse in any way as a result of the operation. Collapse of the lung in war wounds and from other reflex causes has occurred. Why, therefore, should not a shockless operation on a healthy dog be done in opening his pleura without causing collapse of the lung, provided the theory of negative pressure in the thorax maintaining normal lung expansion does not hold true? As we shall see, shock is an important factor, but many other elements enter into the very complex mechanism of respiration.

Experiment 1.—A young, full grown dog of medium size was used. The operation was begun at 1:30 p. m. The area of operation was thoroughly infiltrated with 0.5 per cent. procain. A needle connected with a long glass tube was used to test the negative pressure before the pleura was opened. It was arranged to lift a column of water in the tube, but water was drawn into the pleural cavity, and the lung immediately collapsed, as was shown by the laborious breathing and the retraction of the intercostal muscles. The thorax was opened and the lung was found collapsed, and the diaphragm strongly contracted in tetany. Morphin, 2 grains, was given intramuscularly and air kept from rushing into the thorax on inspiration. The thorax was then closed. The opposite side of the pleural cavity was then opened in a similar manner after injecting 10 c.c. of a 0.5 per cent. solution of cocain into the free pleural cavity. The lung at first protruded from the wound on inspiration, but after a brief exposure to the air the diaphragm remained in tetanic contraction and the lung in its regular rhythmic time relaxed and would not contract again until the diaphragm was released from the tetany and resumed its regular rhythmic contractions, which occurred as soon as the opening in the thorax was closed by pressure of a sponge. The finger was now placed in the pleural cavity acting as a valve in the thoracic wound. The lung was observed to expand in proportion to the extent of the diaphragmatic contractions. The finger was purposely removed several times as the diaphragm was beginning to contract. The force of the contraction in this case was very violent in spite of the fact that there was a sudden inrush of air against both lung and diaphragm. The lung expanded so that it protruded from the pleural cavity.

Experiment 2.—The operation was the same as in the first experiment. The pleural cavity was filled with warm physiologic sodium chlorid solution. Respiration was carried on with the lung on the side of the opening in about half collapse. Very little embarrassment of respiration was noted in this condition. The difficulty was in keeping the pleural cavity full of the fluid because inspiration would almost empty it each time.

Experiment 3.—The operation was done the same as in Experiment 1 except that only 1 grain of morphin was given, because the animal was a female and slightly smaller in size. The wrist of a thin rubber glove, the fingers having first been cut off, was sutured to the soft tissues of the wound just below the skin and made water tight. This was filled with physiologic sodium chlorid solution of about the temperature of the animal's blood. When the pleural cavity was overfilled with the solution we had a column of the solution above the pleural opening which would rise and fall with each respiration and which could be kept at any temperature desired. When the fluid about the lung was below the temperature of the blood, the lung would either collapse or expand much less than the volume of the pleural cavity. When the temperature was raised above that of the blood, the lung expanded so that a part of the lobe remained outside of the pleural cavity in the solution in the rubber glove. It would continue this over-expansion at each inspiration and only slight movements of expiration apparently for an indefinite length of time. A cold sponge was held to the outer surface of the rubber glove so that it came close to the lung which was entirely covered with the solution. The lung was very sensitive to the change of temperature and retracted into the chest cavity and would as quickly reappear when the temperature of the water was raised slightly. All this occurred with the pressure of the air outside the lung plus the weight of the column of physiologic sodium chlorid solution about the lung. A hemostat was clamped over the opening in the rubber glove, and the opposite side of the chest was treated in a similar manner. The opposite lung behaved in a similar way with a positive pressure on both sides of the chest.

CONCLUSIONS FROM EXPERIMENTAL WORK

1. The extent of lung expansion is in direct proportion to the amplitude of the contractions of the diaphragm.
2. Collapse of the lung is a defensive reflex to preserve the normal temperature of the blood.
3. The first expansile effort on the part of the lung when the thorax is opened is a natural effort to plug the thoracic opening.
4. Both expansion and collapse, as defensive reactions, are merely exaggerated uses of the lung reactions in normal life to meet conditions of changing temperature. The adaptation to higher temperatures in normal life is made by sighing and gasping; temperatures too low call for a lessening of the respiratory movements.

The mechanism of this adaptation may be in the nerve endings of the pleura, or possibly are due to a chilling of the blood itself. It is to be remembered that all the blood in the body passes through the lungs in approximately twenty-three seconds;[17] that the thin walls of the lung constitute an excellent radiator, and that animal life cannot exist if the temperature of the blood is reduced to 68 F.[18] If such a defensive reflex were not possessed by animals, no race could survive in the natural state where the law of tooth and claw and "kultur" holds sway. The mechanism of collapse is of the utmost importance to an organ through which passes all the life blood of the entire body within a single minute. The vessels of the lung possess no other vasoconstrictor mechanism. This reaction occurs very suddenly when the stimulus is extraordinary, such as in the opposite side of the chest from that injured by a gunshot wound. Here the reflex centers are so overwhelmed by the stimuli that they send out vigorous but disorderly responses, causing the uninjured lung to contract violently against an incompressible liquid mass, causing hemorrhagic areas as described by Duval.[2]

A hint as to the mechanism of lung expansion is obtained in the study of the lungs of the new-born child. Up to the time of the first inspiration, the lungs are solid like liver; after the first inspiration the bronchioles obtain their proper shape, and the surface of the lung is studded with a few air vesicles, but the remainder retains its fleshlike appearance.[19] A further study of the condition of the newly born was made by Bouchacourt[20] by means of roentgenograms. He found that if air is forced into the child's month, instead of its having breathed spontaneously, gas is found in the stomach and lungs but not in the apexes.

The structure of the lung suggests the mechanism of its expansile power. Circularly arranged muscle always means contraction of the enclosed lumen of any hollow viscus. The larger bronchioles have this circularly arranged muscular structure, while in the smaller bronchioles it is less marked until the terminal bronchiole is reached; these have a well developed muscularis mucosae, with the blood vessels derived from the bronchial arteries a prominent feature, showing that these muscles really function as contractile tissues rather than as a mere retractile mechanism. An illustration copied from Bailey[21] (Fig. 2) suggests the inflating effect of the contraction of the muscles in the walls of the bronchioles.

Thirty-eight cases of empyema have been under treatment in the base hospital at Camp Upton, during the two and a half months' period from which this report is derived. Many of the cases have been chronic; some have become chronic in this hospital, some from other base hospitals on this side, and some from base hospitals overseas; six cases are the result of gunshot wounds of the chest. One case in which the primary operation was done during the period of this report has become chronic, and one case has ended fatally. The chronic condition was due chiefly to three causes:

1. An unresolved bronchopneumonia from *Streptococcus hemolyticus.*
2. An incision not properly placed.
3. Efforts to secure expansion of the lung at a period when collapse should have been maintained and treatment directed toward sterilizing the pleura and permitting the lung lesions to heal. Dakin's solution has been used in chronic cases to dissolve and cut away diseased and dead tissue and deposits of exudate. Dakin's solution has been used in a few very acute cases in which pressure on the lung and the application of cold are indicated to secure immobilization as well as sterilization. The hypertonic solution of boric and salicylic acid according to the formula of Thiersch has been used in all acute cases with open thorax to remove pus and all foreign material mechanically, to inhibit bacterial growth without injuring a delicate pleura, and to produce a lymph lavage according to the teaching of Sir Almroth Wright. As the solution is warm (110 F.), it is found to be the best possible stimulus for lung expansion.

The theory of respiration which attributes to the lung an active power of expansion independent of a negative pressure in the thorax is the outgrowth of a study of the many open chests exposed to view which served as a direct stimulus for investigation, but it is also based in part on the observations of the many keen-sighted clinicians in the war zone whose records have, to a limited extent, been within our reach.[22]

Public Health and Public Welfare in Siam.—Vice Consul Carl C. Hansen at Bangkok reports (*Commerce Reports*, Dec. 27, 1918) that public health and welfare has been advanced during the year in Siam by extending the operation of sanitary regulations to several towns in the provinces. Two American doctors are now in the Siamese sanitary service. Dr. E. M. Barnes, of the International Health Board has successfully cooperated with the Siamese health office in the control of hookworm. American medical men working in the missions, and those doing work among lepers, begun some years ago by Dr. J. W. McKean of the American mission in northern Siam, have received expressions of appreciation by the Siamese government, and contributions toward the expenses of this work have been made during the year.

Clinical Notes, Suggestions, and New Instruments

A CASE OF ACUTE STREPTOCOCCUS MENINGITIS WITH RECOVERY *

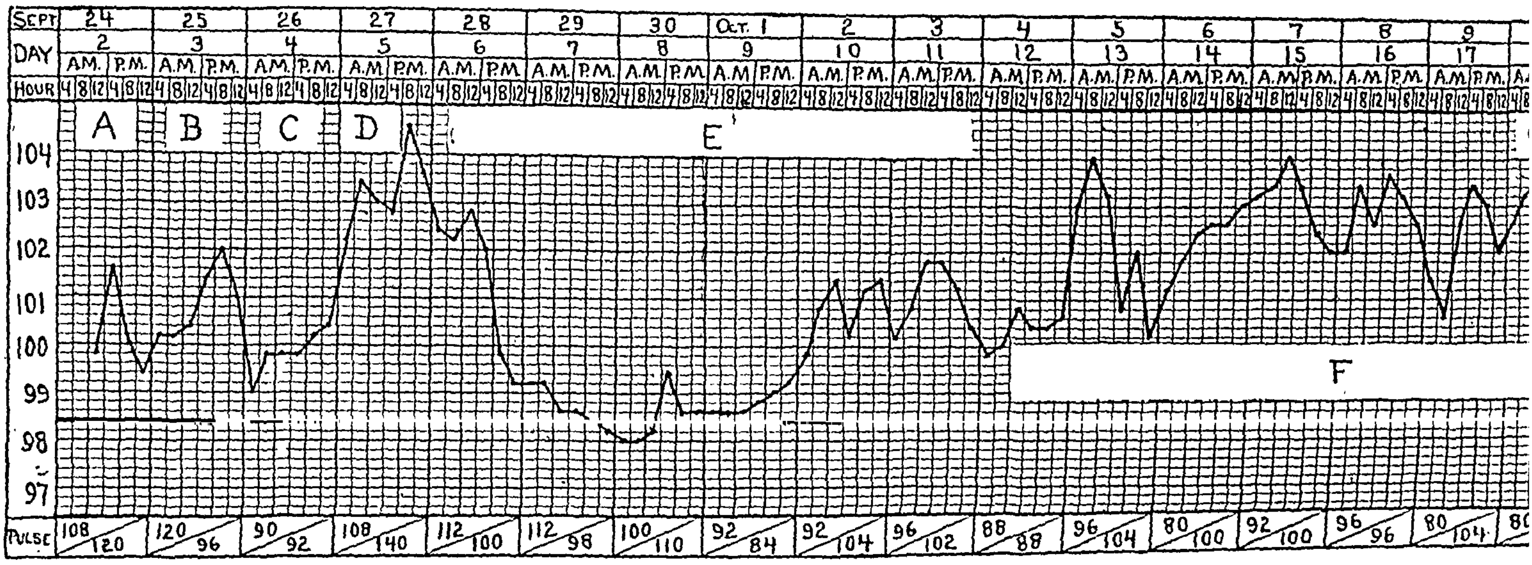
George H. Weaver, M.D., Chicago

This case of meningitis is reported because instances of recovery from streptococcus meningitis are uncommon, and the case presents some other points of interest.

A woman, aged 25, was apparently in perfect health until the afternoon of Sept. 23, 1918, when she became suddenly and violently ill with headache, vomiting, and severe pain in the back of the neck and the back. At midnight a lumbar puncture was made which yielded a turbid fluid containing abundant polymorphonuclear leukocytes. No bacteria were with certainty found in smears. Twenty-seven c.c. of antimeningococcus serum were given intraspinally.

The following morning she entered Durand Hospital. She complained of intense pain in the head, back of the neck and back which was increased when she was moved. There was constant nausea, with occasional vomiting. The neck was rigid. Kernig's sign was positive; her mind was clear. The tonsils had been removed a year before. There was a slight excess of mucus in the nasopharynx, but no acute inflammation. The temperature was 99.8 and the pulse 108. Leukocytes were 10,200, with 87 per cent. of polymorphonuclears. Nothing abnormal was found in the chest or abdomen. Lumbar puncture yielded 25 c.c. of turbid fluid under increased pressure, which contained 2,759 cells per cubic millimeter, most of them being polymorphonuclear leukocytes. No bacteria were recognized in smears, and 20 c.c. of antimeningococcus serum were given intraspinally.

Culture of the spinal fluid on blood agar plates gave a pure growth of small white colonies of a gram-positive streptococcus in moderate numbers. The colonies were surrounded by a narrow semitransparent zone of greenish color after twenty-four hours' growth in the incubator. The organisms were not bile soluble, did not ferment inulin, and were noncapsulated. They were recognized as *Streptococcus viridans*. September 25 and 26, lumbar punctures yielded 30 c.c. of turbid fluids under increased pressure containing about 7,200 cells per cubic millimeter. Abundant colonies of streptococci as described above developed on blood agar plates prepared from the fluids. The patient's condition was more grave, and there was added herpes of the lip, paresis of the right eyelid, and transient hallucinations. The temperature ranged from 99 to 102. September 27, the fifth day of illness, 30 c.c. of turbid fluid under increased pressure were withdrawn, and 21 c.c. of commercial polyvalent antistreptococcus serum were introduced. The temperature during the day ranged from 103 to 104, and the pulse from 108 to 140. During September 28 the temperature gradually fell to 99, and remained between 98 and 99 with a corresponding improvement in pulse, until October 2. October 2 and 3 the temperature ranged from 100 to 101.8, and the pulse from 92 to 104. From September 28 to October 3 there was a severe serum reaction with urticaria. Otherwise the patient was much better and she had little pain. Beginning with October 5 and continuing until October 11, the patient was much worse. There were severe pain in the head and the back, dizziness and blurring of vision, nausea and vomiting, hallucinations, and rambling delirium and a leukocytosis of 10,500. The temperature ranged from 101 to 104, and the pulse from 80 to 112. Lumbar puncture, October 10, obtained 22 c.c. of turbid fluid with 530 cells per cubic millimeter, mostly polymorphonuclear leukocytes. Abundant streptococci were cultivated from the fluid. October 11, a lumbar puncture was made; and after 28 c.c. of turbid fluid under increased pressure had been removed, 22 c.c. of antistreptococcus serum were introduced. During the next twenty-four hours there was a little urticaria, and the temperature fell below normal. From October 12 to October 17, the temperature was between 97 and 99, the pulse 72 to 84, there was very little pain, and the patient was improved in every way.



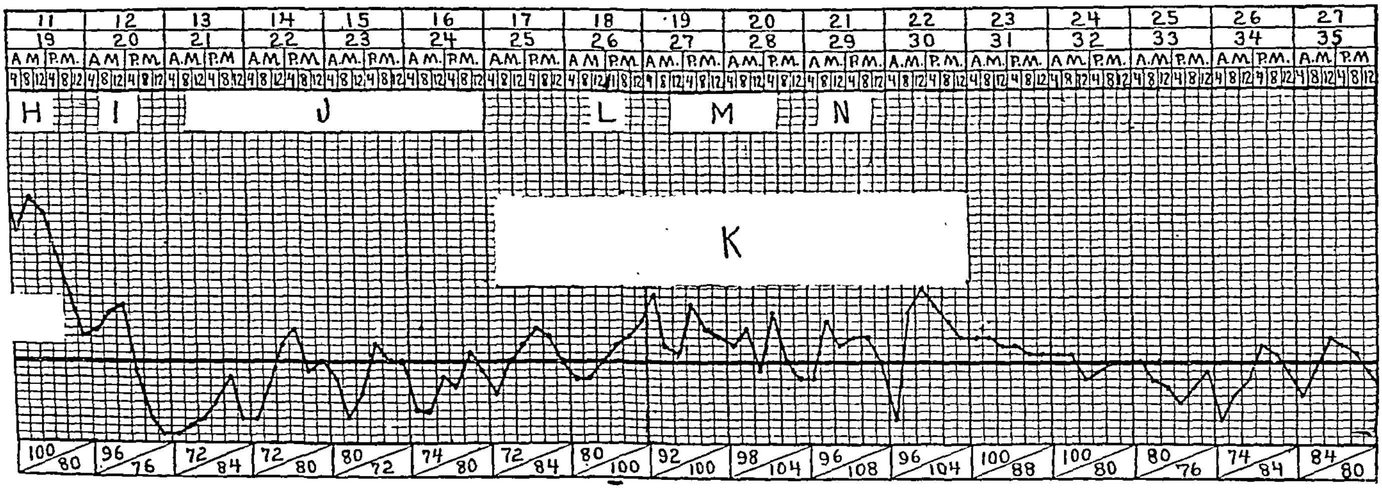
Temperature chart in case of acute streptococcus meningitis: *A*, lumbar puncture; 25 c.c. turbid fluid; 20 c.c. antimeningococcus serum. *B*, lumbar puncture; 33 c.c. very turbid fluid; 7,200 cells per cubic millimeter. *C*, lumbar puncture; 30 c.c. turbid fluid; *D*, lumbar puncture; 30 c.c. turbid fluid; 21 c.c. antistreptococcus serum. *E*, severe serum reaction with urticaria; otherwise, patient much better; little pain. *F*, return of pain in head and back; dizziness and blurring of vision; nausea and vomiting; hallucinations and rambling delirium. *G*, lumbar puncture; 22 c.c. turbid fluid; 530 cells per cubic millimeter. *H*, lumbar puncture; 28 c.c. turbid fluid; 650 cells per cubic millimeter; 22 c.c. antistreptococcus serum.

Between October 17 and October 22 there were vomiting, blurring of vision, diplopia, and spastic tremor of the eyelids. The eyes were examined by Dr. E. V. L. Brown; the disks were a trifle edematous, but there was no tortuosity of vessels nor other evidence of intracranial pressure The pupils reacted normally. Lumbar puncture, October 18, secured 14 c.c. of turbid fluid with 1,200 cells per cubic millimeter and with a moderate number of streptococci. October 19 and 20, there was violent urticaria. October 21, 25 c.c. of antistreptococcus serum were given intramuscularly. October 23, the temperature fell to 99 and never again rose above normal. From then on the recovery was rapid and complete. Repeated and thorough examinations of the ears, nose and throat by Dr. Robert Sonnenschein failed to detect any condition that might have been the focus of infection primary to the meningitis. It was suspected that the ocular symptoms from October 17 to October 22 were due in part to intracranial disturbances accompanying the serum reaction, of which a severe urticaria, October 19 and 20, was a part.

The improvement that followed each administration of antistreptococcus serum was striking. In cases of streptococcus meningitis, which are usually hopeless, the combined intraspinal and intramuscular administration of antistreptococcus serum would seem to be worth trying. The curative action of antistreptococcus serum depends largely on its opsonic content,[1] as does that of antimeningococcus serum, and the serum should theoretically be useful in such a condition as meningitis, in which it can be brought in direct contact with the bacteria.

---

* From the Durand Hospital of the John McCormick Institute for Infectious Diseases.



I, slight urticaria. *J*, little pain; general condition much improved; patient wants to sit up. *K*, vomiting; blurring of vision; diplopia; disks a trifle edematous, but no tortuosity of vessels nor other evidence of intracranial pressure; tremor of eyelids; pupils react normally. *L*, lumbar puncture; 14 c.c. fluid; 1,200 cells per cubic millimeter. *M*, intense urticaria. *N*, 25 c.c. antistreptococcus serum intramuscularly. Respirations the first day were 20, and remained about that rate throughout the illness.

LATENT INFECTION AT THE HILUM FOLLOWING INFLUENZA

Harold S. Arnold, M.D., New Haven, Conn.
Major, M. R. C., U. S. Army

The routine examination of the lungs of a large number of soldiers at Vancouver Barracks, a post where demobilization took place early, and where the epidemic ocurred comparatively late, showed that certain physical signs persisted at the hilum of the lungs for a considerable length of time after apparent recovery from the epidemic disease. A large proportion of these patients showed no symptoms, but occasionally one complained of cough. This finding suggested a careful investigation of the lungs of all patients evincing any symptoms of septic absorption, regardless of whether or not there was anything to suggest lung involvement. The routine examination has demonstrated that findings persist at the hilum either as an accompanying condition or as the cause of lowered resistance in a considerable number of patients. The most frequent complaint is that of prostration. Various myalgias, headache, backache, neuralgias and vague or localized joint pains are usually present; sore throat and cough are almost constant. The symptoms are those associated with some infection or with simple intestinal absorption.

They may abate temporarily after calomel and a saline purge are administered, but will recur. In another class of patients, repeated colds, sore throat or sinus trouble leads to application for a "thorough overhauling."

The character of the cough shows considerable variation, depending on the presence or absence of a general bronchitis or on the condition of the throat rather than on the hilum involvement. If the relaxation of the palate lets the uvula drag, the cough is paroxysmal. It may or may not be productive. Three cases occurred in persons who had undergone long treatment for sinus trouble. The patients felt greater prostration in the late afternoon sometimes accompanied by a rise in temperature.

Examination generally revealed little. The amount of redness of the throats and nasal mucous membranes varied not a little and was not always an index to the amount of subjective discomfort. Edema of the fauces, and particularly of the uvula, seemed far more general.

A superficial examination of the chest will not disclose the lesion. Inspection, palpation and percussion may demonstrate nothing but an occasional slightly increased dulness on either or both sides of the vertebral column above and below the level of the angles of the scapulae. *The findings are determined by auscultation.* The transmission of the voice sounds is usually unaltered, although there is sometimes an increased sense of distance and muffling. The breath sounds follow the same rule. By far the most valuable measure in this, as in cases of tuberculosis, is the employment of expiratory cough. The patient is directed to exhale and to utilize the last remnant of air in a cough sufficient to shake the chest walls, and then to inhale without undue gasping. A shower of moderately fine, sticky râles which seem to burst fairly near the ear is heard with the cough and immediately after.

The treatment by means of drugs is unsatisfactory. Mechanical measures designed to increase the flow of blood locally are of some benefit. Nothing, however, does this better than the daily use of a large, enveloping, old fashioned mustard poultice. The main reliance should be placed on such measures as are of the greatest value in cases of tuberculosis; a properly regulated diet, fresh air and, most important of all, absolute rest of mind and body. If this rest is not obtainable at home, the patient should be sent to a place where it is possible to obtain complete rest while under strict medical supervision.

The symptoms in these cases so resemble in most instances those for which we investigate sinuses, tonsils, teeth and appendixes that the possibility of chronic trouble at the hilum should be borne in mind and an examination of the back made as a routine measure, at least until the epidemic and its after-effects have become a thing of the past.

HEMORRHAGIC DISEASE IN THE NEW-BORN

Arthur D. Kurtz, M.D., Philadelphia

The hemorrhagic diseases of the new-born have always been of marked interest, and it is for this reason that these two cases are reported.

Case 1.—A boy, whose delivery had been normal after a short labor, the fourth child of healthy parents, whose personal and family histories were negative as to hemorrhage, was circumcised seven days after birth, no sutures being used, with no unusual bleeding at the time of operation, the wound being dressed with boric acid and a narrow bandage. The wound began to ooze about fifteen hours after operation, the bleeding coming from no particular point. The usual local hemostatics were used, but without result, so a continuous suture of 00 catgut was used to unite the skin and mucosa. This had no other effect than to cause the stitch holes to ooze. A commercial hemostatic was then used locally, with no effect. Ten c.c. of normal horse serum were then injected into the abdominal wall, and as this produced no result, another 10 c.c. were given about two hours later. This also had no effect, and Dr. William A. Steel was called in consultation. He suggested centrifuging some of the father's blood and injecting the serum, which was done, 15 c.c. being injected. The oozing stopped shortly after, and the child made an uninterrupted recovery. He is now 4 years of age, has had the usual number of cuts and bruises that an active child sustains, and has shown no further evidence of a hemorrhagic tendency.

---

[1] Weaver, G. H., and Tunnicliff, Ruth: Further Studies of Antistreptococcus Serum, J. Infect. Dis. 9: 130, 1911.

Case 2.—A girl, the third child of healthy parents with negative family and personal histories, was delivered by a high forceps operation. The eldest child, a girl, has a severe case of icthyosis, and the second child, a boy, has had several minor surgical operations with no unusual bleeding. The patient exhibited no marks from the blades of the forceps except on the right cheek. There was no hemorrhage from the cord after tying. The child nursed and cried normally and showed no untoward symptoms until the third day after delivery, when there appeared on both cheeks the marks of the forceps blades. Within a few hours after these marks appeared, the skin broke down and began to ooze a pinkish serum; on the upper portion of the helix of the right ear, a small point appeared which bled freely. As local hemostatics had no effect, 10 c.c. of normal horse serum were injected in the abdominal wall. Almost immediately the hole where the needle had entered began to ooze, and the navel then started oozing; but no point could be found that could be tied. Sodium citrate enemas were given, as we felt that since the needle holes only made another point to bleed, we could not inject any more serum. The child rapidly sank, and died at noon on the fourth day after delivery. This case is of interest, as hemorrhagic disease is stated to be rather rare in females, the proportion, as stated by Campbell and Kerr, being twelve males to one female.

RETRACTORS MADE WITH HAIRPINS

Angelo L. Soresi, M.D. (New York)
Surgeon, Italian Army
Milan, Italy

In minor surgical operations, when special retractors are not available, ordinary hairpins may be utilized. Such retractors are effective and economical, and may be used in many ways. They can be made self-retaining by placing a weight on the end (Fig. 1 *g* and Fig. 2). In minor operations they are sometimes ideal: they can be widened or narrowed as necessary (Fig. 1 *c, f*) at different steps of an operation. If the incision should be widened, the points of the pin also can be proportionally widened, without resorting to a change of retractors; even in the case of certain operations when large retractors are needed, the pin can be enlarged to advantage and a second pin put between the branches of the one that has been widened (Fig. 2).

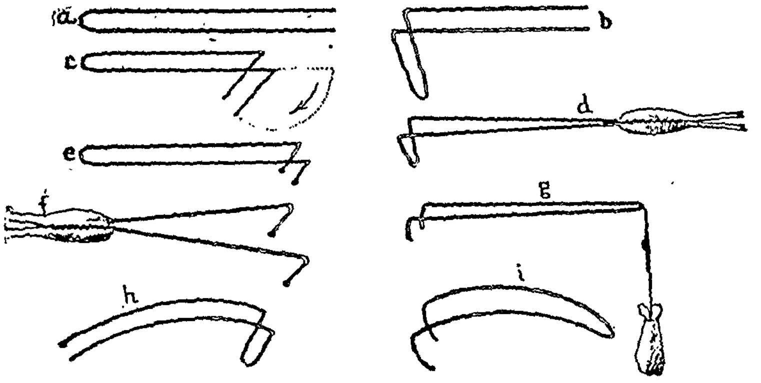

Fig. 1.—Ordinary hairpin (*a*) bent so as to form: *b*, a blunt retractor, and *c*, a hooked retractor; *d*, hairpin hold on artery forceps; *e*, hairpin having small knobs at the end and forming a blunt-pointed retractor; *f*, points more separated so as to form a wider retractor; *g*, self-retaining retractor; *h*, *i*, hairpins bent so as to follow the curve of the body.

Forceps, held by an assistant, may be attached to the side of the pin that is not bent, and by bending either the points or the top of the pin, one can obtain either a hooked or a blunt retractor. If a very strong retractor is required, hairpins used by women to curl the hair should be employed. If sharp pointed retractors are wanted, pins with sharp points are selected; if, on the other hand, blunt pointed retractors are preferred, pins having a small knob are utilized (Fig. 1 *c, f*). All these varieties of pins are easily obtainable at a dry goods store.

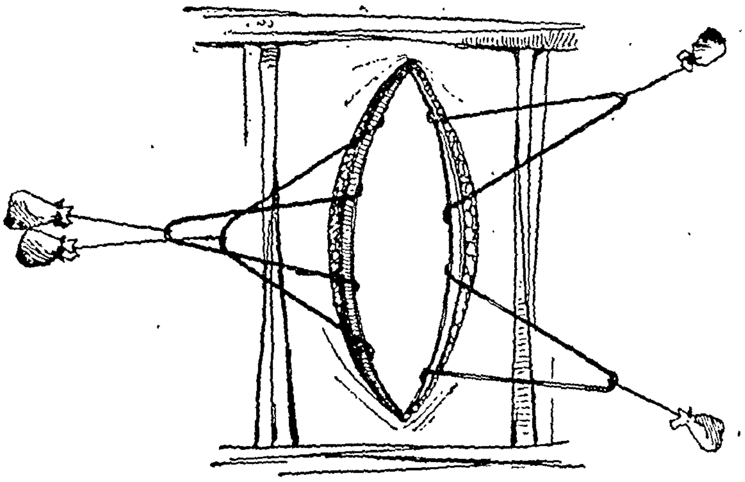

Fig. 2.—Method of applying self-retaining hairpin retractors when a large surface has to be retracted.

A great advantage of using hairpins as retractors is that they can be bent so as to follow the curves of the part on which they are used, so that the retraction can be made without changing the natural position of the tissues that have to be retracted (Fig. 1 *h, i*).

Ospedale Militare Principale.

THE RELATION OF THE PNEUMOCOCCUS TO THE PRODUCTION OF ACID IN FLUID CULTURE MEDIUMS AND THE REACTION OF THE PNEUMONIC LUNG *

Frederick T. Lord, M.D., Boston

The pneumococcus may continue to live in plain bouillon and in calcium carbonate-glucose bouillon for a period of from three to six months. Its viability in glucose bouillon without calcium carbonate is only a few days. The acidity of a 1 per cent. glucose bouillon culture, for example, rises rapidly, as indicated by titration from an initial reading of 0.3 c.c. twentieth-normal sodium hydroxid to 3 c.c. twentieth-normal sodium hydroxid and by colorimeteric determination of the H-ion concentration from an initial reading of from 7.3 to 5.5 with death of the organisms. That an increase in the acidity is to be regarded as an important factor in the death of the organisms is suggested by the fact that the addition of calcium carbonate to the glucose bouillon before implantation of the pneumococcus maintains the life of the culture for a long period, and that after reimplantation of a realkalinized glucose bouillon without calcium carbonate the pneumococcus again grows.

Determination of the H-ion concentration of the press juice of the exudate in lobar pneumonia by the dialysis method showed in three of four human cases a greater degree of acidity in the pneumonic exudate than in the press juice of the other lung used as a control. In the fourth case the H-ion concentration of the pneumonic lung and the other lung was the same.

---

* From the Massachusetts General Hospital. Presented at the meeting of the American Society for Clinical Investigation, Washington, D. C., May 8, 1916. Subsequent work on this subject was interrupted by the war. I am indebted to Drs. Porter, Newburgh and Means for some of the material in connection with the experimental pneumonia in dogs.

The pneumonic exudate in experimental Friedländer and pneumococcus pneumonia in dogs was likewise more acid than the press juice of other organs and the blood. In one dog, with experimental pneumococcus pneumonia, the H-ion concentration of one involved lobe was 6.00, and that of another 5.40. From the former, pneumococci were grown in pure culture, but from the latter no growth of pneumococci was obtained.

An increased acidity, indicated by a determination of the H-ion concentration, may be demonstrated also in sputum obtained from patients with lobar pneumonia. It is also found, however, in the purulent sputum from other patients, in empyema pus, and pus from abscesses due to other organisms than the pneumococcus.

The pneumococcus can usually be cultivated from the exudate of lobar pneumonia, even when the acidity is high. Since, however, that part of the lung involved in lobar pneumonia is in a measure isolated from other parts of the body, it is possible to conceive of important local changes of a biochemical nature taking place within it, such as the inhibiting effect of acid production on the growth of the pneumococcus and the favoring influence of increase in acidity on enzymatic action.

305 Beacon Street.

STAINING OF BACTERIA IN TISSUES FOR BACTERIOLOGIC STUDY OF PNEUMONIC FOCI

A MODIFICATION OF METHOD, AS APPLIED ESPECIALLY TO THE PFEIFFER BACILLUS

Kuyoshi Sato, M.D., Tokyo, Japan
Staff Physician, Pathologic Laboratory, Red Cross Hospital

There are many rules and directions laid down for the staining of bacteria in tissue, especially when microphages and macrophages are concerned; but the most important requirement is that, while the cell protoplasm shall be moderately bleached, the nuclei and the bacteria shall become and remain plainly visible. Last fall a pandemic of influenza swept over Japan. In investigations undertaken to ascertain the morphology and the incidence of the bacterial phenomena, many of the staining methods did not produce the best results, but with my modification of the carbolfuchsin staining-fluid satisfactory results were achieved.

MODIFIED STAINING METHOD

1. The frozen sections should be cut as thin as possible and glued to the object glass by means of an egg-white glycerin mixture.
2. They should be stained for a period of from ten to twenty minutes in a solution of carbolfuchsin which has been prepared by dissolving 1 c.c. of carbolfuchsin in 10 c.c. of water.
3. The differentiation is accomplished by the use of weakly acidulated warm water (two drops of glacial acetic acid to about 250 c.c. of water). The sections should be left in the solution until they take on a rose-violet hue.
4. The sections are now rinsed in water.
5. They are then dried in the air, no alcohol being used.
6. They are afterward transferred to a xylene bath and are then embedded in a neutral balsam.

FINDINGS

The bacteria are stained all the way from a light to a very dark red. The nucleus takes on a deep red hue, while the protoplasm is almost colorless.

This method is adapted to the staining of any prepared sections in connection with bacteriologic study.

The Perfect Man.—The hygienic ideal continues to be the same as expressed in the Roman proverb, "mens sana in corpore sano," which as interpreted by the Spanish physician Letamendi, means the body of an athlete, the mind of a scholar, and the soul of a saint.

HOSPITAL SERVICE IN RURAL COMMUNITIES

A PRELIMINARY REPORT

Prepared by Ernst C. Meyer, Director of the Department of Surveys and Exhibits of the Rockefeller Foundation International Health Board
NEW YORK

(Continued from page 1293)

PART III. SERVICES WHICH SMALL HOSPITALS IN RURAL COMMUNITIES CAN RENDER

Future Rôle.—The essential work of a hospital lies in the field of curative medicine. It is hardly necessary, however, to point out that to care for properly and to cure disease is also to prevent it. In fact, it is not unlikely that when the hospital has found its place of greatest usefulness in the scheme of work for health preservation, its influence as a preventive agency will overshadow even its highly important function in the curative field.

Growing the Hospital from the Hearts of the People.—All experience would seem to point to the fact that a community hospital in order to enjoy its full measure of usefulness must be grown from the hearts of the people whom it is to serve. To do this, public sentiment must as a rule be painstakingly educated. The idea of hospital service is new, and prejudice against it widespread. It is of peculiar interest that this prejudice should be greatest among those who would benefit most by the service. Wherever it was possible, through a tactful, energetic and thorough campaign to coax a community hospital from an originally indifferent, because unknowing public, the benefits have been so evident and so widely enjoyed that the hospital has invariably had warm support and has experienced constantly increasing usefulness.

A hospital is one of those institutions which is peculiarly helpless unless the public comes to it. Those who wish to establish such an institution must seek to find the right way rather than the quick way to do so. Not the grafted hospital—in the form of a private benefaction—but the home grown variety, seems to appeal the most. There is the difference between going after something that is wanted, and receiving something not thought of before. In the first instance, use and enjoyment are immediate and spontaneous. In the second, liking and desire must first be cultivated. It has been found that during this period of cultivation the hospital is apt to go through a stage of hard times both financially and medically.

Aside from these general thoughts, certain advantages of a specific character may be enumerated. They are grouped with respect to their bearing on the patient, the community and the physician.

BENEFIT TO THE PATIENT

A few illustrations of what proper hospital care means in specific types of sickness will serve as an introduction to this rather trite summary of the bright side of the community hospital.

Emergency Cases.—The usefulness of a community hospital is nowhere more apparent than in the emergency or accident cases, in which often the least delay in operating may cause fatal results. The experience of some 150 small hospitals serving largely rural communities in Pennsylvania showed that about 80 per cent. of the cases which came to these hospitals were surgical, and that from 75 to 80 per cent. of the surgical cases were in turn emergency cases. In other words, about 65 per cent. of all cases in these small hospitals fell in the emergency class.[10]

Typhoid.—Hospital care is of immense importance in the care of typhoid. The mortality rate, in the rural regions, in 1910 for this disease was 23.3 per hundred thousand. The stamping out of typhoid is one of the great current tasks of preventive medicine. Its prevalence is well recognized as a serious reflection on any community. Treatment in the hospital will mean better care, quicker discovery of complications, quicker treatment, and better disinfection. Perforation of the intestine, which annually causes 2,500 deaths in this country out of 8,000 cases, could be so handled in hospitals as to save most of this loss of life. In the country a patient with this complication is described as having "no more chance for existence than a snowball in a kettle of boiling water."

Rheumatism.—In vital statistics, rheumatism appears as an apparently insignificant cause of death—7.4 per hundred thousand population. As a matter of fact, it is said that 50 per cent. of the deaths due to organic heart disease (141.5 per hundred thousand, or greater than that of tuberculosis of the lungs, which was 139.7) in 1910 were due to rheumatism. Moreover, numerous deaths reported to be due to other causes are directly traceable to heart failure. Thus, where a case of pneumonia or typhoid is fatal, owing to a crippled heart, the acute disease is usually reported as the cause of death.

Rheumatism is one of the diseases which, it is said, should have "a watchman all the time." The life or future usefulness of a patient may depend on the early detection of heart complications. Rarely, it is said, do patients who live in the country districts and who are suffering from acute rheumatism receive the benefit of hospital care. It is of interest, too, that usually it is difficult to prevail on a patient to provide himself with suitable nursing at home, or even to tolerate watchfulness on the part of a physician.

Pneumonia.—Few diseases need closer watching at certain stages than pneumonia. Judicious and well-timed medication may tide the patient over the crisis to recovery. The cases need careful observation by nurses, and frequent attention from physicians.

Appendicitis.—A famous surgeon has said: "We should have no deaths from appendicitis, but we are having them"—about 8,000 a year for the country. Prompt medical and surgical attention and hospital care are the requisites.

Maternity Care.—One of the great functions which the community hospital may serve is to offer facilities for adequate maternity care, and incidentally to save thousands of lives of mothers and infants. No less than 15,000 mothers died from diseases and accidents incident to childbirth in 1910, and no less than 70,000 deaths occurred from premature birth and diseases peculiar to early infancy. Authorities seem to agree that these deaths are largely preventable. Nor do the cold figures reveal the whole sorrowful story. Gargues has strikingly stated one aspect of this problem: "The poorest, the dirtiest, the most dissolute women are safely confined in a hospital; the richest, the youngest, the purest, and the loveliest sometimes succumb in giving birth to a child at their own homes."

Infectious Diseases in General.—The importance of an isolation ward in a community hospital is obvious. Failure properly to isolate a patient may result in an entire community's becoming infected. In no case is the need of a hospital more apparent.

Advantages of Good Medical Care.—Patients treated in a properly equipped local hospital generally are assured of good medical care. They are in the hands of trained nurses and subject to constant supervision—important in many diseases of a fluctuating character. The hospital always furnishes appliances superior to those that can be obtained in the best home. It should be in a position to meet any unforeseen developments that may arise.

Suitable Food and Surroundings.—In many cases the patient cannot at home be provided with proper food which, even if prepared by a trained nurse, is not likely to come up to hospital requirements, where the diet is a departmental matter. The general accommodations, moreover, and quiet surroundings are another factor which greatly contributes to the speedy convalesence of a hospital-treated patient.

Better Air.—Although this may not apply to the wealthier members of the community, the poor patients certainly breathe purer air in the hospital than at home. Besides being spaciously constructed, the hospital usually occupies an isolated position, surrounded by trees, and provided with open-air verandas and balconies where patients may enjoy the full benefits of convalescence.

Family Relieved of Care of Patient.—The fact that the burden of responsibility in caring for the patient is shifted from the family—usually poor and hard-working—to the hospital has a salutary effect both on the patient and his family, and by reducing the inevitable worry which accompanies all sickness, facilitates a more speedy recovery.

Reduction of Expenditure.—Another recommendation in the eyes of the poor is the fact that while receiving better care, their expenses are lowered by being treated in the hospital; the indigent poor are, of course, relieved of all financial obligations.

Educational Work.—While in the hospital a patient acquires the fundamentals of healthy living and medical care. On his return home he is more competent to look after himself and his family.

Advantages of Community Hospital over City Hospital.—In many cases the needs of a country patient can be successfully met by the city hospital, where he is furthermore assured of receiving the best attention. Very often, however, the distant hospital is unable to be of any assistance, and the simpler, less highly organized service of the local hospital can alone avail. The following are the main advantages of the community hospital over the city hospital:

---

[10] This fact only serves to emphasize the tragedy of hospital service in rural communities in Pennsylvania. According to the published reports of the state, 75 per cent. of these hospitals are "incompletely equipped and grossly mismanaged."

Avoidance of Transportation: In some cases a patient would suffer very severely through delay in transportation to a city. This is especially true in surgical cases. In remote country districts, moreover, the facilities for transportation are either entirely lacking or are exceedingly primitive in character. Often the patient has to be taken for 50 or 60 miles over rough roads in a poor conveyance. The presence of a hospital in the immediate community would eliminate this difficulty.

Expense: Both the distance of transportation and the superior equipment offered by a city hospital make it more expensive than the rural hospital. For the majority of country people this is a factor of importance.

Follow-Up Work: Very often it is highly important that a case be followed up after the patient is discharged. He may be too ignorant to care for himself, or his case may need constant supervision at the hands of the physician who has treated him. This can be carried out effectively only if the patient lives in the same locality in which the hospital is situated. The work of the visiting nurse is furthermore a great factor in educating the patient in everything pertaining to his physical well-being.

Individual Attention: Although from a medical point of view this may be a minor consideration, nevertheless from the subjective view of the sick patient the local hospital offers large advantages over the city institution, in that he is much more likely to be treated as a human being instead of as a mere "case." He enters into personal relations with the hospital staff who, he feels, are anxious to see him recover. And he is apt to leave the hospital full of gratitude and affection, this sentiment being quickly communicated to his family and neighbors. Too often the very opposite is true of the large city hospitals, even when the patient may have received the best professional care. The importance of this psychologic factor is happily becoming more widely recognized.

BENEFIT TO THE COMMUNITY

Community Responsibility.—The possession of a local hospital tends to arouse a community to a sense of its responsibility toward its sick. The public is too much inclined to rely on public charity and occasional donations to relieve it of this burden. It should be made to realize that the sick need its continuous support just as much as does any other department of public service, and that by looking after its sick it is serving its own immediate interests.

Educational Value.—The hospital, being in close touch with the people, can do effective work in educating the people in matters pertaining to healthful living. Every patient who enters a hospital is taught the elements of right living and of medical self-help. The lessons thus learned are spread throughout the community.

Reduction in Mortality and Morbidity.—Many deaths are averted through more prompt and adequate medical assistance furnished by the hospital. General health education increases healthful living. Communities owning rural hospitals have experienced a reduction in mortality and morbidity.

Cooperation in Public Health.—The hospital can be made an active collaborator of the public health department. It may serve as an intermediary between it and the community at large, with which it is in intimate touch. Through a well-developed system of visiting nurses it will be able not only to care for its patients but also to carry on a very active educational propaganda in the interests of sanitation and the control of epidemics. Thus results can be accomplished which quantities of leaflets spread among a population including the illiterate and ignorant cannot possibly effect.

Branch Laboratory.—The community hospital, if it is equipped with a laboratory, as it should be, both pathologic and bacteriologic, might develop into an important branch of the state laboratory service, where diagnostic work may be quickly done. Time, in many instances, is a vital factor in preventive health work. Specimens may likewise, when necessary, be forwarded to the state laboratory in prescribed form. The local laboratory may naturally also become a seat for more or less stimulating and practical research work.

BENEFIT TO THE MEDICAL PROFESSION

Hospital as Meeting Place.—The local hospital can serve as a center where the physicians of the community may gather, exchange opinions, and familiarize themselves with the latest advances in medical and hospital methods. It stimulates healthy competition and eliminates the rivalries and misunderstandings which too often result from isolated activity.

Stimulates Study.—Altogether too frequently it happens that a physician relegated to a rural district becomes a fossil. Unless animated by high ambition he may be inclined to let himself drop to the level of his surroundings, and not being subject to supervision, and usually inadequately paid, he tends to relax his standards. The presence of a community hospital acts as a very potent spur to a country practitioner's activities, and usually prompts him to endeavor to keep abreast of the times by taking postgraduate courses in medicine and in other ways. This desire is further stimulated if the hospital offers him the advantage of an up-to-date medical library.

Increases Efficiency.—The hospital greatly increases a physician's ability to render efficient service in accordance with modern standards. Proper facilities, especially in surgical cases, are not available in the ordinary country home. Usually a physician cannot maintain his own hospital. The community hospital provides a place to which he can bring surgical and other cases which need constant supervision, and which in the absence of a hospital he often must take to his own home. The presence of a hospital also lessens the physician's chance of contracting an infection, and saves both time and money.

Tends to Elevate Moral Standards.—Hospital practice is apt to discover and expose crime and graft in the form of unnecessary operations, wrong diagnosis for the sake of prolonging treatment, unwarranted division of fees, etc. It has been suggested that under such conditions great surgeons will become greater, and good physicians and surgeons better; that the poor, careless, indifferent few who endanger society, and who are the curse of reputable medical men, will be driven out of the profession.

THE MEDICAL MANUAL OF THE AIR SERVICE

When the history of the great war through which the United States has just passed is fully recorded, the influence of the unusual problems, suddenly created by the requirements of the fighting forces, on the progress of scientific study will become conspicuous. One need not go beyond the medical and closely related sciences to realize the significance of this statement. Feeding an army of millions instead of thousands of persons raised anew many questions of food and nutrition which had either been overlooked or complacently disregarded under the ancient regimen. The importance of avoiding waste loomed larger than ever before at a time when we were being exhorted to conserve food to the utmost and to use substitutes so that those less able to do without certain food products might share our surplus in larger measure. Sanitary science and practical hygiene were confronted with new difficulties in the creation of great cantonments and camps, and the introduction of new modes of warfare, such as trench fighting. Water supply and sewage disposal required suitable provision on an enormous scale, often in places presenting unanticipated difficulties. Accordingly, the organization of a large sanitary corps, the initiation of a food division, the introduction of the designation "nutrition officer," are illustrations of a few of the innovations created by the novel needs of the times.

In medical fields the almost revolutionary changes in methods and principles of diagnostic, therapeutic and prophylactic procedure are still too new to leave the impression of importance which some of their unique aspects deserve. It was a platitude that, in war, more men die of disease than by bullets; but just as the implements of war change in successive generations, so the incidence of army maladies varies in different places and seasons. No sooner had the prophylactic conquest of typhoid, once a dreaded sourge, relieved the army command of one enormous danger, than typhus, trench fever, meningitis, pneumonia and influenza came on the scene in unanticipated ways and with unexpected virulence. Other omnipresent deteriorating forces, like the venereal diseases, adopted unsuspected modes of insidious attack calling for the utmost resourcefulness to prevent serious human disaster. The ravage caused by the war gases presented absolute novelties of pressing necessity to the medical fraternity, bringing it face to face, literally overnight, with pathologic manifestations never encountered before.

The fruitfulness of medical research in the solution, partial or complete, of the seemingly innumerable new difficulties that have confronted it in the past two or three years has manifested itself in so many abiding ways that it is not easy to select the most representative examples. Despite the perennial interest that centers in such topics as shock, infectious disease or plastic surgery, they do not possess the temporarily popular fascination which the novel experiences of gas warfare or aviation present as scientific curiosities. Medical studies in aviation have more than merely military value: they involve matters likewise of economic and human import. Colonel Wilmer, who has been the officer in charge of the Medical Research Laboratory of the Air Service at Mineola, L. I., has forcefully indicated the point of view emphasized by war time needs. Though the principles of aeronautics, he writes,[1] were clearly enunciated by Samuel Johnson 159 years ago in his "Rasselas, Prince of Abyssinia," it was not until within the last decade that air flights began to be practical. During these years, infinite time and thought have been spent on the machine. The pitch of the screw, the angle of attack, the stream line, the admixture of gasoline and air, etc., have all been studied with mathematical accuracy. But the value of the human machine, Wilmer adds, is just beginning to be properly recognized. A slack control wire is not more dangerous than a weak eye muscle; a poor mixture of gas and air is not more serious than a flier with poor adaptive respiration. And a poor compression in the cylinder is not of such vital consequence as a weak heart muscle.

The new air service has thus been faced with the physiologic problem of determining the conditions which may affect the efficiency of the aviator, and the medical problem of protecting him against the effects of altitude, low barometric pressure, and deficiency of oxygen. Some of the timely contributions from the newly created laboratory have already been reviewed in The Journal.[2] More recently the government has issued a manual of the Medical Research Laboratory[1] from the Division of Military Aeronautics in the War Department. It is the result of the work done in the well equipped laboratory at Mineola, and is intended for the information and instruction of those who are interested in the medical problems of aviation. In addition to an illuminating discussion of the physiology of altitude which concerns the mountain climber as well as the air pilot, the peculiar concern of psychology, otology, ophthalmology and psychiatry in the conditions involved in flying is interpreted.

[1] Manual of Medical Research Laboratory, War Department, Air Service, Division of Military Aeronautics, Washington, D. C., 1918, p. 5.

[2] Medical Studies in Aviation, J. A. M. A. **71**: 1382 (Oct. 26) 1918. Medical Aspects of Aviation, editorial, ibid. p. 1408.

Few persons not primarily accustomed to think of the factors involved in human efficiency realize what individual physical fitness really means. Why do we read of so many "ologies" in relation to the aviator? The ability to endure comfortably and well high altitudes, the government manual tells us, is dependent on the ease and quickness with which the adaptive responses in the breathing, the blood and the circulation take place. In persons damaged by disease, overwork or unhygienic living, or weakened by inactivity and by loss of sleep, the power of adjustment is as a rule below par. The normal equilibrium of the body is so nicely adjusted that under usual conditions the physiologic balance is largely maintained by adjustments that are made with little or no expenditure of energy.

There is a certain range of greater or less breadth through which the external factors of the environment may be varied and yet be met by an automatic adjustment of the physiologic processes in the body which will preserve the vital balance of the mechanism. The eyes, ears, cardiovascular mechanism and nervous system play a part in these adjustments. Until the effects of the airman's activities and environment on the functions of different organs are accurately known, the health and the efficiency of the aviator cannot be completely safeguarded. The new manual is a sign of the stamina of American men of science acting in united effort under the spur of a great need.

HAND-BORNE INFECTIONS

It is easy for the absent-minded, as well as for the ignorant person, to transfer germs from contaminated hands to the mouth. Objects touched by fingers just moistened with saliva are a part of the everyday environment of many persons in modern life. Telephone directories consulted with freshly dampened thumbs, saliva-moistened street-car transfers, and hands offered for the ceremonial shaking after being used for smothering the droplets of a cough are but a few of the multitude of opportunities for acquiring germs fresh from the respiratory tracts of friends, acquaintances and strangers. Others will be recalled by every observant city dweller. Opportunities, indeed, for hand-soiling of even more unpleasant character are not far to seek.

The chances for hand contamination during an active day are extraordinarily numerous. Palmer[1] has recently enumerated his chances for acquiring infection of this sort; they amounted to 119 points of contact. The majority of them were instances of hand contact with doorknobs and similar objects that were or might have been touched by others immediately before. Many active men would probably go far beyond such numbers in counting over their own possible daily chances for hand contamination. It is safe to say that the average professional man or office worker in the "down town" or "business" district of a city takes advantage in the course of a day of several hundred opportunities for picking up germs of various kinds recently deposited by the hands of others. Under special conditions, this form of indirect contact has been thought to be a potent factor in definite epidemics of diseases. Lynch and Cumming[2] have advanced evidence which is interesting, if not altogether convincing, in support of the view that contaminated hands were an important agency in spreading influenza in certain army organizations during the great 1918 pandemic. The hands of typhoid carriers have for a long time been regarded with well merited suspicion.

There are two aspects of hand-borne infection that deserve special recognition. One is the fact that early education of the reflexes can protect the individual to a large extent against the grosser forms of this mode of infection. It is glaringly obvious that the biting of finger-nails, the moistening of fingers in turning the pages of a book, and similar half unconscious acts greatly enhance the opportunities for planting undesirable germs where they can multiply. On the fingers they may be harmless; transferred to the mouth they have a wide field for development. It is plain, too, that hand washing before meals constitutes a safeguard against infection. The soiling of the hands is impossible to avoid altogether, but the swallowing of germs from one's own soiled hands is largely under individual control. A reasonable degree of education in such matters in the home and in the school will go a long way toward minimizing the dangers of hand-borne infection.

Another aspect is the evident absence of any ground for extreme apprehension or for the building up of a phobia. Every normal, active person must receive on his hands hundreds of times a day germs derived from other human beings, and yet apparently infection from this source is relatively uncommon. In proportion to the chances for hand contamination, adult infection is certainly a rare occurrence. Undoubtedly in children of school age and younger this route of infection is more commonly followed; but two additional factors are at work in the latter case; the greater susceptibility of children to the common infections whose portal is the mouth or the nose, and the more unconventional habits of children with respect to cleanliness of hands and familiarity of intercourse between fingers and mouth. Even with children, however, it is difficult to apportion the relative responsibility of hand-borne infection and droplet infection.

---

[1] Palmer: Am. J. Pub. Health 9:267 (April) 1919.

[2] Lynch and Cumming: J. Am. Pub. Health Assn. p. 1919.

So far as adults are concerned, the proportion of cases of hand-borne infection to the opportunities for such infection seem almost surprisingly small. It may be fairly assumed that the most useful safeguards against this form of disease transmission are to be found in such practices as hand-washing and in refraining from using the tongue or the lips as a moistening-pad, rather than in hysterical attempts at avoidance of all hand contamination. Children are best protected through the inculcation of similar desirable habits at an early age. In a word, some degree of hand contamination is unavoidable; but the transference of the contaminating germs to the mouth is largely under individual control and is subject to the powerful influence of early formed habit.

FOOD AND THE CONTROL OF BACTERIA IN THE INTESTINE

The alimentary tract of man has been designated as a graveyard for bacteria. No less than from 5 to 8 grams of them, dead for the most part, are excreted every day with the feces. One need not debate whether these micro-organisms are in general beneficent or detrimental to the body. Certainly at times some of them, at least, produce more harm than good. Early in the history of modern alimentary bacteriology the attempt was frequently made to devise some procedure for sterilizing the gastro-intestinal tract by destroying those bacteria which escape the germicidal bath of the acid gastric juice. The efforts resulted in failure. Such substances as might have been effective bactericides were as a rule so detrimental to the human host that it became a choice between survival of both the latter and his invader or the simultaneous destruction of the two.

Subsequently it became apparent that the intestine may be the location of quite different types of bacteria. One group, which may be designated as the putrefactive class, thrives particularly in the large intestine, where the reaction is not unfavorable. Where the second group, the fermentative bacteria, thrives, acid conditions are likely to arise which inhibit the growth of the putrefactive micro-organisms. Still other varieties like *B. coli,* are adjustable to varied conditions of environment. Herter and Kendall[1] were the first to emphasize the correlation between the types of bacteria found in the intestine and the composition of the ingested food. According to them, in the absence of carbohydrates in the diet the proteolytic bacteria predominate, so that the fecal discharges give evidence of the products of the putrefactive changes brought about by them.

Other American bacteriologists have also recorded the transforming influence exerted by certain foodstuffs on the intestinal flora. For example, Torrey[2] observed the peculiar effects of high-calory diets on the fecal micro-organisms of typhoid patients. The food fuel in such cases contains an unusual quantity of lactose, amounting at times to 250 grams and upward. On such a regimen there resulted a transformation of the ordinary type of flora to one strongly dominated by *Bacillus acidophilus.* More recently, at the Cornell University Medical College, New York, Torrey[3] has demonstrated anew, by experiments on dogs, that the chemical character of the food ingested is the factor controlling the types of bacteria vegetating in the alimentary tract. It does not follow, however, that all carbohydrates have an equal tendency to establish a purely fermentative intestinal flora; nor do all protein foods encourage putrefactive conditions in like degree. Torrey observed that two carbohydrates, lactose and dextrin, added to a diet of meat and rice, caused such a marked development of aciduric bacteria of the *Bacillus acidophilus* type that they completely dominated the fecal flora and effected the almost complete suppression of proteolytic types, even including *B. coli,* commonly found in the dog's intestinal tract. Glucose exercised no transforming influence; and maltose and sucrose caused at most only a minor alteration in the direction referred to. Whether this is due to a slower absorption of lactose so that it can act as a bacterial medium, owing to a longer sojourn in the lumen of the intestine, is not determined. At any rate, the results are more than transitory: they persist as long as the special diet is continued.

Starchy foods also tended to effect a simplification of the intestinal flora and an elimination of the obligate putrefactive bacteria. Protein foods produced decidedly unlike effects, so far as the encouragement of putrefactive organisms is concerned. Thus, milk casein in the diet exhibited far less tendency to give rise to putrefaction than did meat protein—a fact long since recognized on the basis of chemical examination of the urine for evidences of absorbed decomposition products. Fats in the diet seem in general to be without determining influence. Torrey announces that vegetable proteins stand in strong contrast to proteins of animal origin, and meat in particular, in that they do not offer encouragement to the growth of intestinal putrefactive types of bacteria. We shall expect our vegetarian friends to disseminate this fact widely in their always vigorous admonitions against the "dangers" of meat, now that the "uric acid poison" proclamations are no longer so effective as formerly. We shall not participate at this moment in the debate of bread and milk versus meat and potatoes. For the present it is gratifying enough to know that where antiseptics fail to produce desired results, as in the hidden recesses of the bowel, diet may prove to be an unexpectedly potent factor in the purposeful restraint of undesirable inhabitants.

THE EPIDEMIOLOGY OF POLIOMYELITIS

The increasing knowledge of the distribution of the micro-organisms that are the etiologic agents in the occurrence of several epidemic diseases has focused attention on the prevalence of carriers, formerly unsuspected as factors of danger to the environment in which they exist. The demonstration that apparently healthy persons may harbor bacteria of a pathogenic sort is now accepted universally in the case of the organisms responsible for typhoid fever and diphtheria. Healthy carriers are by no means always immune to the germs which they innocently harbor, as the experience with hemolytic streptococci, responsible for the secondary infections following in the wake of scarlet fever, measles, smallpox and influenza, clearly indicates.[1]

It is not doubted at present that there are healthy carriers of the virus of poliomyelitis, regarding the epidemiology of which much remains to be ascertained. The virus has been detected in the secretions of the nasopharynx not only during the period of attack by the disease but also in healthy persons who have been in contact with cases of poliomyelitis.[2] Obviously an intelligent method of control of the spread of an epidemic presupposes dependable information regarding the distribution of the etiologic agent. Swedish observers[3] have championed the view that chronic carriage of the virus of poliomyelitis is common; but the painstaking critical and experimental studies just reported from the Laboratories of the Rockefeller Institute for Medical Research by Flexner and Amoss[4] are not in accord with this conclusion. Their deductions are to the effect that the virus is regularly present in the nasopharynx in cases of poliomyelitis in the first days of illness, and especially in fatal cases; that it diminishes relatively quickly as the disease progresses, except in rare instances; and that it is unusual for a carrier state to be developed. Hence the period of greatest infectivity of patients would appear to be early in the disease, which is probably the time at which communication of the virus from person to person takes place.

The American investigators adduce, in support of their conclusion, the observation that the communicability of poliomyelitis during the wide epidemic in this country in the summer and autumn of 1916 was a phenomenon chiefly of the early stages, while the frankly paralyzed person and the convalescent were to be feared much less. Correspondingly, at the Rockefeller Institute experimental infection was secured with tissues obtained during the first week, approximately, of the disease, but not at later periods. It seems unlikely, therefore, that healthy and chronic carriers of the virus are numerous. In any event, preventive measures against the spread of epidemic poliomyelitis should unquestionably be centered on the actual patients and particularly early in the course of their infection.

Current Comment

CONSTITUTIONALITY OF HARRISON NARCOTIC DRUG ACT UPHELD BY SUPREME COURT

The United States Supreme Court has decided that the Harrison Narcotic Drug Act is constitutional. The exact status of this law has been a matter of discussion since its passage. While it had been variously interpreted by United States district and appellate courts, its constitutionality had never been passed on by the United States Supreme Court. In two decisions, involving practically the same points, the Federal Supreme Court holds the act constitutional and rejects the claim that it is an invasion of the police power reserved to the states. In the first case, United States vs. Doremus, the district court of the western district of Texas held the act unconstitutional on the ground that it was not a revenue measure and was an invasion of the police power of the states. The evidence shows that Doremus, a physician who was duly registered and who had paid the tax required by the act, sold to a patient, a morphin habitué, 500 one-sixth grain tablets of heroin, the sale not being in pursuance of a written order on one of the forms furnished by the Internal Revenue Department. The court says that the Harrison law was passed under article 1, section 8, of the constitution, which gives congress the power to lay and collect taxes for the general welfare, and that the only limitation placed on the power of congress is that such taxes must be uniform. To this limitation the Supreme Court declares that it cannot add others. Subject to such limitation, congress may select the subjects of taxation and may exercise the power conferred at its discretion. The fact that other motives may impel the exercise of federal taxing power does not authorize the courts to inquire into that subject. If the legislation enacted has some reasonable relation to the exercise of the taxing authority conferred by the constitution, it cannot be invalidated because of the supposed motives which induced it. Nor is it sufficient to invalidate the taxing authority given to congress by the constitution that the same business may be regulated by the police power of the state. An act may not be declared unconstitutional because its effect may be to accomplish another purpose as well as the raising of revenue. If the legislation is within the taxing authority of congress, that is sufficient to sustain it. This means that so long as an act is in proper form as a tax measure, congress may regulate anything that it may desire through its tax-levying power without regard to whether the subject is one that may be regulated by the states or whether the real object of the act may be reformatory or restrictive rather than revenue producing. So long as the law is a tax-levying law in proper form, the courts will not go into the motive for which the act was passed. Evidently this decision represents the opinion of a bare majority of the court, since it is signed by only five justices, the chief justice and three other members of the court dissenting and holding that the district court correctly held the act to be beyond the constitutional power of congress in that it was an attempt by congress to assert a power not delegated, that is, the reserved police power of the states. Chief Justice White and Justices McKenna, Van Devanter and McReynolds, the dissenting justices, evidently regard the Harrison act as an invasion of the police power of the states and not a proper subject for federal legislation. The decision was written by Mr. Justice Holmes, and the justices concurring are Day, Pitney, Brandeis and Clarke. The second case, Webb and Goldbaum versus the United States, involves the same issue. On this, as on the previous decision, the court was divided five to four.

VICTORY WEEK IN ATLANTIC CITY

The Chicago session of the American Medical Associaton was called a war meeting. The Atlantic City session will also be a war meeting, but with a very different point of view from that of last year. This is to be a VICTORY MEETING. War is an expensive but a practical teacher. In its crucible medical science has been put to the test and vital knowledge evolved. The therapeutics and diagnostic methods of peace times are, in war's stern trial, stripped of their fripperies and fringes, and proven facts and true scientific knowledge take their place. The VICTORY MEETING of the Association will be largely devoted to the presentation of what science has gained and what facts have been gleaned in the war. Necessarily, as was the meeting last year, this VICTORY MEETING must be more or less international in character, hence invitations have been sent to foreign governments to send representatives to be present and to contribute their knowledge to this vast symposium. A prominent feature will be the application to industrial life of those war methods which are particularly applicable because they deal with the handling of large bodies of men under control, and because they deal with injuries which are duplicated by those in industrial life. Then, too, this VICTORY MEETING will offer one of the first real opportunities for a study of the havoc wrought by the influenza epidemic and the means for combating future scourges of similar character. By June ninth many medical officers—perhaps more than 20,000—will have been released from military service. Thus there will be the opportunity to meet and greet the friends of military life and to reminisce over the stirring trials of war times, whether in camp, in field service, in the laboratory or in the administrative offices. It is not too much to say that the victory meeting will be an epoch making session. In view of the important and serious discussions to take place, the Fellows of the Association are especially to be congratulated that the meeting occurs in Atlantic City where ocean breezes, balmy sunshine and invigorating and soothing ocean baths keep the mental faculties eternally fresh.

HELPFUL HINTS FOR BUSY DOCTORS

A comparatively recent issue of the *International Journal of Surgery* had an editorial on "The Questionable Etiology of the Present Epidemic." The editorial, which occupied nearly two columns, was signed "G. H. Sherman, M.D." and its sum and substance was to the effect that one can best immunize against influenza by using "a combined vaccine containing the influenza bacillus, pneumococci, streptococci, the micrococcus catarrhalis and staphylococci." In the advertising pages of the same issue was a half-page advertisement of "Influenza Vaccine No. 38" which "Will abort Colds, Grippe, Influenza and Pneumonia" and which is made by "G. H. Sherman, M.D." This vaccine contains the various bacilli and cocci mentioned in the G. H. Sherman, M.D., editorial. In the good old days, some medical journals published editorials puffing proprietary remedies. Then, however, the editorials were unsigned, being rewritten by the editor from material furnished by the advertiser. Twentieth century efficiency has improved on the old re-write method. One wonders whether in coming issues of the *International Journal of Surgery,* one may look for an editorial by Bell & Co. (which also carries a half-page advertisement) on "The Questionable Etiology of Sick Headache," which we learn from the advertising pages "is quickly and surely relieved by six Bell-ans in a glass of hot water." Or possibly one may find "The Questionable Etiology of Chronic Intestinal Stasis" discussed editorially by the French Lick Springs Hotel Co., who surely should be accorded two columns of editorial space, as they carry two quarter-page advertisements of "Pluto." A four-page editorial is rightly due the Etna Chemical Co. for its full-page advertisement of "Phenalgin," and it should not be difficult to use that amount of space in discussing "The Questionable Etiology of Pain." Interesting editorial subjects suggest themselves as one reads the advertisements of "Sal Hepatica," "Ergoapiol," "Pond's Extract," "Micajah's Suppositories," "Tongoline," "Bromidia," "Campho-Phenique," "Sanmetto," "Pepto-Mangan," and many, many others of similar scientific merit!

THE ADMINISTRATION OF ARSPHENAMIN

Elsewhere in this issue appears a letter from Dr. George W. McCoy, director of the hygienic laboratory of the United States Public Health Service, concerning two special points in the administration of arsphenamin, namely, the dilution and the rapidity of administration. His letter is followed by a circular issued by the Public Health Service to all its officers covering the same general subject. Numerous disagreeable results following the use of the various preparations of arsphenamin have led research workers to make a special study of the cause of these accidents. Such studies have indicated that most of the disagreeable results are not inherent in the preparations themselves, but are produced through faulty steps in the administration of the remedies. The suggestions made in the circular of the Public Health Service, if followed by physicians, will aid in preventing repetition of disagreeable after effects.

MENINGOCOCCUS INFECTION

In view of the experience of army physicians in finding many cases of infection with the meningococcus without any evidence of meningitis, Major Herrick, chief of the medical service at the base hospital, Camp Jackson, has urged the abandonment of the term epidemic cerebrospinal meningitis.[1] This suggestion is not an entirely new one; but the considerations on which it is based have apparently not gained sufficient prominence hitherto to emphasize the extrameningeal rôle of the meningococcus through the use of a suitable designation for the general sepsis which this micro-organism may initiate. Practitioners should realize more widely what the unusual clinical facilities of the army base hospitals have emphasized, namely, that a definite meningococcus septicemia not infrequently occurs in which the primary invasion is in the blood stream. Herrick insists that the cerebrospinal distribution of the disease is by no means specific, since other micro-organisms, such as tubercle bacilli and the *Spirocheta pallida* have the same localization. Furthermore, there may be a meningococcic sepsis with involvement of the joints, the pericardium or other structures; hence the designation of cerebrospinal should not be stressed to the exclusion of other symptoms. There is something more than a mere verbal quibble involved in directing attention to the existence of meningococcic sepsis without meningitis. This emphasis, says Herrick, is imperative, because on it is based that modified therapy which, in proper hands, has mitigated the severity of the disease and greatly reduced the mortality—the intravenous serum treatment.

AMPUTATIONS AS WAR DISABILITIES

In the popular mind amputations of the limbs are inevitably conspicuous features of the casualties of warfare. The thought of a battle-scarred veteran of the Civil War commonly brings to mind an armless or legless victim of the damage done by shot and shell. It will come somewhat as a surprise, therefore, to those not conversant with the precise nature of the disabilities of the recent European campaigns to learn how unexpectedly small is the total of those whose wounds and injuries have necessitated amputation. The War Risk Insurance Bureau has issued the statement that approximately 4,000 men of the American Expeditionary Forces have lost arms or legs, and that about 125 have been blinded. There are several reasons which may account for this unanticipated small incidence of amputations among the many thousands of disabled members of the fighting forces of the United States. By the time we entered the war the hospitals had begun to move nearer to the front where the casualties occur. Consequently the injured received treatment far more promptly than in the earlier years when many hours or even days sometimes intervened before adequate surgical care could be given to the wounds. Delay inevitably means increased liability to infection and permanent damage of the affected tissues; whereas the more prompt surgical intervention of the last year of the war has ofttimes permitted the salvation of a wounded member. Furthermore, the methods of wound treatment have progressed to a higher degree of efficiency, which has brought about a corresponding sparing of life and limb. In the treatise of military surgery published by Hans von Gerssdorff at Strasburg in 1517 under the title "Feldbuch der Wundartzney" he states that he had personally performed "nearly two hundred amputations." According to Buck[1] this great increase in the frequency of performing the operation is clearly to be attributed to the increased use of the new agent—gunpowder—in warfare. *Tempora mutantur!*

Medical Mobilization and the War

Personnel of the Medical Department

For the week ending May 2, there were 18,113 officers in the Medical Corps, a decrease of 454 from the previous week. The Medical Reserve Corps contained 1,799 officers. The total number of medical officers discharged since the beginning of the war is 15,552.

HONORABLE DISCHARGES, MEDICAL CORPS, U. S. ARMY

Note.—In the following list, L signifies lieutenant; C., captain; M., major; L. C., lieutenant-colonel; Col., colonel.

ALABAMA

Birmingham—Lull, C., Jr. (M.)
Grand Bay—Dodson, R. B. (C.)
Montgomery—Haigler, J. R. (C.)
Selma—Maas, M. A. (M.)
Vernon—Box, T. T. (L.)

ARKANSAS

Beebe—Abington, W. H. (M.)
Hope—Kolb, A. C. (L.)
Little Rock—Hickman, S. B. (C.)

CALIFORNIA

Fresno—Martin, W. P. (L.)
Los Altos—Rice, P. (C.)
Los Angeles—Brem, W. V. (M.)

ORDERS TO OFFICERS OF THE MEDICAL CORPS, U. S. ARMY

Alabama

To Army Medical School, from Camp Dix, Lieut. S. B. GAILLARD, Perdue Hill.

To Camp Custer, Mich., camp hospital, from Camp Dix, Capt. R. D. BROWN, Mobile.

To Fort McPherson, Ga., from Charleston, Capt. W. W. BURNS, Selma.

To Westville, N. J., from Charleston, Capt. B. F. ADAMS, Fulton.

To Williamsbridge, N. J., from Long Beach, Lieut. G. LOTTERHOS, Birmingham.

Arkansas

To Camp Pike, Ark., base hospital, from Camp Dix, Major M. D. OGDEN, Little Rock.

California

To Alcatraz Island, Calif., from Camp Sherman, Capt. W. P. MILLIKEN, Oakland.

To Camp Kearney, Calif., from Camp Dix, Major H. G. MARXMILLER, Los Angeles.

To Denver, Colo., from Fort D. A. Russell, Major K. B. TURNER, Los Angeles.

To Fort Des Moines, Iowa, from Camp Dix, Capt. A. L. FISHER, San Francisco.

To Spartanburg, S. C., from Fort Oglethorpe, Lieut. A. O. HOLMES, Redlands.

To St. Louis, Mo., from Fort Winfield Scott, Lieut. D. P. McCORD.

To Walter Reed General Hospital, D. C., from West Baden, Major C. E. PHILLIPS, Los Angeles.

Canal Zone

To report to the commanding general, Canal Zone, from Panama Canal, Major H. HANSON, Ancon.

Colorado

To Camp Upton, L. I., N. Y., from Walter Reed General Hospital, Lieut. W. D. FLEMING, Denver.

Florida

To Fort Riley, from Camp Grant, Capt. O. W. KING, Sanford.

Georgia

To Otisville, N. Y., from Camp Dix, Capt. R. E. McCLURE, Alto.

To Walter Reed General Hospital, D. C., from Fort McPherson, Major W. E. HALL.

The following order has been revoked: *To Fort Oglethorpe* for instruction, Lieut. J. O. BALDWIN, Fort Gaines.

Illinois

To Camp Dix, N. J., from Camp Custer, Capt. E. H. PARRY, Galesburg. Base hospital, from Camp Gordon, Capt. G. FITZ-PATRICK, Chicago; from Newport News, Capt. G. O. De MOSS, Cropsey.

To Camp Dodge, Iowa, base hospital, from Camp Custer, Lieut. A. W. CHRISTENSON, Rockford.

To Camp Grant, Ill., from Camp Custer, Capt. H. P. BAGLEY, Chicago.

To Columbus Barracks, Ohio, to examine the command for cardiovascular diseases, from Fort Sam Houston, Lieut. F. M. SMITH, Chicago.

To Detroit, Mich., from Camp Dix, Lieut. H. J. DWYER, Chicago.

To Fairfield, Ohio, Wilbur Wright Field, from Hot Springs, Capt. S. W. WILLIAMS, Eldorado.

To Fort Riley, from Camp Grant, Capt. K. M. MANOUGIAN, Kankakee; from Camp Lee, Lieut. H. E. RANDOLPH, East Moline.

To Fort Sheridan, Ill., from Camp Dix, Capt. N. C. MORROW, Chicago; Lieuts. F. W. FIEDLER, Batchtown; T. A. CARTER, I. H. CUTLER, A. S. SANDLER, Chicago; from Camp Grant, Lieut. W. E. GATEWOOD, Jr., Chicago; from Charleston, Lieuts. P. A. STEELE, A. VANDERKLOOT, Chicago.

To Fox Hills, N. Y., from Washington, D. C., Lieut. J. STEVENSON, Chicago.

To Otisville, N. Y., from Camp Dix, Capt. R. H. HENDERSON, Chicago.

To report to the commanding general, Philippine Department, from Fort Riley, Capt. B. I. WYATT, Chicago.

Indiana

To Chicago, Ill., from West Baden, Capt. C. R. STRICKLAND, Indianapolis.

To Denver, Colo., from Camp Dix, Lieut. R. W. REID, Union City.

To Fort Riley, from Camp Shelby, Capt. H. M. SHULTZ, Logansport.

To Fort Sam Houston, Texas, base hospital, from Fort Oglethorpe, Capt. H. B. SHACKLETT, New Albany.

To Fox Hills, N. Y., from Camp Dix, Major R. A. VIOSINET, Union City.

To Hoboken, N. J., from Camp Dix, Capt. M. A. FARLOW, Milroy.

The following order has been revoked: *To Fort Des Moines, Iowa*, from Camp Dix, Lieut.-Col. H. O. BRUGGEMAN, Fort Wayne.

Iowa

To Camp Dodge, Iowa, base hospital, from Fort Douglas, Capt. I. E. NERVIG, Sioux City.

To Fort Benjamin Harrison, from Camp Sherman, Capt. E. L. HAWKINS, Council Bluffs.

To Fort Des Moines, Iowa, from Camp Dix, Lieut. G. V. CAUGHLAN, Pacific Junction.

To Walter Reed General Hospital, D. C., from Hoboken, Capt. H. R. CONN, Cedar Rapids.

Kansas

To Fort D. A. Russell, Wyo., from Newport News, Capt. T. L. JONES, Fulton.

The following order has been revoked: *To Pittsburgh, Pa.*, from Jefferson Barracks, Lieut. A. B. OECHALE, Stockton.

Kentucky

To Camp Meade, Md., from Camp Dix, Major C. W. McCLANAHAN, Maysville.

To Camp Pike, Ark., base hospital, from Washington, Major B. F. ZIMMERMAN, Louisville

To Fort McHenry, Md., from Camp Dix, Capt. G. P. GRIGSBY, Louisville.

To Walter Reed General Hospital, D. C., from Camp Dix, Lieut. K. D. WINTER, Louisville.

Louisiana

To Fox Hills, N. Y., from Colonia, Major K. W. NEY, New Orleans.

To Walter Reed General Hospital, D. C., from Camp Shelby, Lieut. V. W. MAXWELL, Ferriday.

Maryland

To Camp Dix, N. J., base hospital, from Boston, Lieut. E. H. HEDRICK, Baltimore.

To Fort McHenry, Md., from Charleston, Capt. J. H. TRABAND, Jr., Baltimore.

To Fort Mott, N. J., from Curtis Bay, Md., Capt. H. A. NAYLOR, Pikesville.

To Fort Riley, from Camp Shelby, Major H. R. CARTER, Jr., Baltimore.

To Hoboken, N. J., from Camp Dix, Capt. M. H. TODD, Galloways.

The following order has been revoked: *To St. Louis, Mo.*, from Camp Dix, Capt. W. H. SMITH, Jr., Hagerstown.

Massachusetts

To Boston, Mass., from Camp Lee, Capt. A. A. FENTON, Norwood; from Newport News, Lieut. L. STRAHLMANN, Boston.

To Camp Custer, Mich., from Camp Devens, Col. J. H. ALLEN. As orthopedic surgeon, from Fort Slocum, Lieut. M. A. GILBERT, Chelsea.

To Camp Gordon, Ga., base hospital, from Camp Dix, Capt. R. B. OBER, Springfield.

To Fort McHenry, Md., from Camp Meade, Lieut. W. H. BLANCHETTE, Fall River.

To New Haven, Conn., from Saybrook, Conn., Capt. A. P. PERRY, Boston.

Michigan

To Camp Custer, Mich., from Camp Jackson, Majors A. E. HARRIS, Detroit; A. J. WARREN, Mount Clemens; G. P. SACKRIDER, Owosso; Capts. W. HAUGHEY, Battle Creek; G. P. RAYNALE, Birmingham; R. A. SHANKWILER, G. VAN RHE, Detroit; R. U. ADAMS, W. E. COLLINS, Kalamazoo; Lieuts. I. G. DOWNER, A. McARTHUR, Detroit.

To Detroit, Mich., from Camp Dix, Capt. J. T. HODGEN, Grand Rapids.

To Fox Hills, N. Y., from Charleston, Lieut. W. R. MANLOVE, Jr., Grand Rapids.

To Mineola, N. Y., Hazelhurst Field, from Wichita Falls, Lieut. J. L. DESROSIERS, Detroit.

To Washington, D. C., from Camp Custer, Lieut.-Col. S. S. CREIGHTON.

Minnesota

To Fort Riley, from Camp Grant, Capt. E. L. HALL, Russell; Lieut. J. R. WOOD, Hallock.

To Fort Snelling, Minn., from Fort Bliss, Lieut. H. E. CANFIELD, Willmar.

To Spartanburg, S. C., from Fort McPherson, Capt. L. G. NEAL, Ponemah.

To Walter Reed General Hospital, D. C., from Carlisle, Lieut. B. A. BAIRD, Rochester.

To Wichita Falls, Texas, Call Field, from Taliaferro Field, Lieut. T. F. McCORMICK, Minneapolis.

The following order has been revoked: *To Fort Oglethorpe* for instruction, Lieut. H. G. BLANCHARD, Waseca.

Missouri

To Camp Sherman, Ohio, base hospital, from Fort McPherson, Capt. W. E. MEANWELL, Columbia.

To Fort McPherson, Ga., from Fort Riley, Major L. T. PIM, St. Louis.

To Fort Riley, from Camp Lee, Lieut. E. BAKER, St. Louis.

The following orders have been revoked: *To Camp Abraham Eustis, Va.*, camp hospital, from Pig Point, Lieut. E. V. KRING, St. Louis. *To Camp Zachary Taylor, Ky.*, from Jefferson Barracks, Lieut. J. L. HUTTON, St. Louis.

Nebraska

To Fort Riley, as orthopedic surgeon, from Fort Des Moines, Lieut. C. W. WAY, Wahoo.

To Fox Hills, N. Y., from Williamsbridge, Major A. C. STOKES, Omaha.

New Hampshire

To Camp Devens, Mass., base hospital, from Walter Reed General Hospital, Lieut. J. C. LAWLOR, Dover.

New Jersey

To Camp Dodge, Iowa, from Hoboken, Lieut.-Col. C. E. McBRAYER.

To Chicago, Ill., as department surgeon, from Camp Dix, Col. W. B. BANISTER.

To Colonia, N. J., from Camp Dix, Major Z. L. GRIESEMER, Roselle; from Camp Dodge, Lieut. J. S. MARK, Chrome.

To Columbus Barracks, Ohio, from Hoboken, Lieut.-Col. C. C. DEMMER.

To Walter Reed General Hospital, D. C., from Camp Dix, Major H. C. MOORE.

To Washington, D. C., Surgeon-General's Office, from Camp Dix, Col. E. E. PERSONS; Major J. B. EDWARDS, Leonia.

New York

To Camp Dix, N. J., base hospital, from Pittsburgh, Capt. J. J. SINNOTT, Mount Vernon.

To Camp Jackson, S. C., base hospital, from West Baden, Lieut. L. SASOVER, New York.

To Camp Upton, N. Y., as tuberculosis examiner, from *Spartanburg*, Capt. J. C. DEVRIES, Brooklyn.

To Carlisle, Pa., from West Baden, Lieut. H. BLAUVELT, Brooklyn.

To Colonia, N. J., from Walter Reed General Hospital, Major E. HANSON, New York.

To Detroit, Mich., from Camp Custer, Capt. J. J. CORBETT, Syracuse.

To Fort Benjamin Harrison, from Walter Reed General Hospital, Lieut. J. HARKAVY, New York.

To Fort Hamilton, N. Y., from Fort Slocum, Capt. J. C. E. DAUNAIS, Cohoes.

To Fort McHenry, Md., from Camp Dix, Lieut.-Col. J. W. JAMESON, Major W. W. WEEKS, New York; from Detroit, Lieut. C. W. DEMONG, Syracuse.

To Fort Riley, from Camp Lee, Lieut. J. F. LEWIS, New York.

To Fox Hills, N. Y., from Camp Dix, Major C. W. HOYT, Rochester; Capt. R. P. HUYCK, Herkimer; Lieut. W. G. H. POTT, New *York*; from Charleston, Capt. E. C. FOSTER, Penn Yan; from Hoboken, Major A. C. MARTIN, Rockville *Center*; *from* Oteen, N. C., Lieut. R. C. *BULLEN*, New York; from Walter Reed General Hospital, Capt. B. H. CAPLES, New York.

To Hoboken, N. J., from Charleston, Capt. A. W. BRENNAN, Syracuse.

To Metuchen, N. J., from Schenectady, Capt. G. W. WILLCOX, Hamilton.

To Oteen, N. C., from Camp Lee, Major W. C. McKNIGHT, New York.

To report to the commanding general, Northeastern Department, from Long Beach, Lieut. B. R. BASS, Brooklyn.

To Walter Reed General Hospital, D. C., from Camp Upton, Lieut. M. M. NEMSER, New York; from Long Beach, Major E. B. NEFF.

To Washington, D. C., Surgeon-General's *Office*, *from* Camp Dix, Lieut.-Col. W. B. REID, Rome.

The following orders have been revoked: *To Camp Sherman, Ohio, to examine the command* for cardiovascular diseases, from Jefferson Barracks, Lieut. C. SHOOKHOFF, Brooklyn. *To Fox Hills, N. Y.*, from Camp Dix, Lieut. W. E. CARROLL, New York.

North Carolina

To Biltmore, N. C., from Camp Dix, Lieut.-Col. W. L. DUNN, Asheville.

To Camp Grant, Ill., base hospital, from Camp Dix, Capt. L. F. MAGRUDER, Albemarle.

To Fort Riley, from Camp Lee, Lieut. R. T. UHLS, Franklinton.

Ohio

To Camp Devens, Mass., base hospital, from Walter Reed General Hospital, Lieut. W. H. MILLER, Columbus.

To Camp Dodge, Iowa, from Camp Dix, Major A. H. DUNN, Chillicothe.

To Carlisle, Pa., from Charleston, Lieut. R. G. GROSSMAN, Cleveland.

To Fort McHenry, Md., from Camp Dix, Capt. E. R. TWACHTMAN, Cincinnati.

To Walter Reed General Hospital, D. C., from Camp Dix, Major E. J. McCORMICK, Toledo; Lieut. W. E. DWYER, Cleveland; from Camp Jackson, Capt. R. F. DRURY, Akron.

The following orders have been revoked: *To Fort Oglethorpe* for instruction, Capt. M. H. CARMEDY, Painesville. *To Philippine Department,* from Camp A. A. Humphreys, Capt. H. S. HAYES, Whitehouse.

Oklahoma

To Camp Zachary Taylor, Ky., base hospital, from Camp *Dix*, *Capt.* C. E. NORTHCUTT, Lexington.

To Fort D. A. Russell, Wyo., from Fort Benjamin Harrison, Capt. G. H. WETZEL, *Sapulpa*.

To report to the commanding general, Western Department, from San Francisco, Lieut. C. P. MURPHY, Redrock.

To Westville, N. J., from Camp Jackson, Capt. B. F. ADAMS, Fulton.

Oregon

The following orders have been revoked: *To Fort Leavenworth, Kan.*, from Camp Lewis, Lieut. D. R. ROSS, Salem. *To San Francisco, Calif.*, from Camp Lewis, Capt F. J. ZIEGLER, Portland.

Pennsylvania

To Boston, Mass., from Camp Dix, Major W. BATES, Philadelphia.

To Camp Abraham Eustis, Va., camp hospital, from Washington, Capt. W. S. STEWART, McDonald.

To Camp Gordon, Ga., base hospital, from Spartanburg, Lieut.-Col. J. H. STEARNS, Delaware Water Gap.

To Camp Meade, Md., from Camp Dix, Major W. E. RAKEN, Philadelphia; from Camp Shelby, Major T. W. PENROSE, Philadelphia.

To Columbus Barracks, Ohio, from Camp Zachary Taylor, Capt. H. D. JORDAN, Allentown.

To Eastview, N. Y., from San Francisco, Capt. R. J. HENDERSON, Bowmansville.

To Fort McHenry, Md., from Camp Dix, Capts. I. M. BOYKIM, N. R. GOLDSMITH, S. R. SKILLERN, Jr., Philadelphia.

To Fort Riley, from Camp A. A. Humphreys, Major A. E. DAVIS, Scranton.

To Fox Hills, N. Y., from Hoboken, Capt. R. C. FAGLEY, Kulpmont.

To Pittsburgh, Pa., from West Baden, Lieut. D. T. DITCHBURN, Arnot.

To Walter Reed General Hospital, D. C., from Camp *Dix*, *Capt.* W. W. PROPST, Philadelphia; Lieut. W. H. MACKAY, Harrisburg.

To Washington, D. C., and on completion *to Roland Park*, from Eastview, Capt. R. R. DECKER, Orbisonia. Surgeon-General's Office, from Camp Dix, Lieut.-Col. E. L. ELIASON, *Major* F. C. KNOWLES, Lieut. M. W. BLAIR, Philadelphia.

South Carolina

To Biltmore, N. C., from Camp Sevier, Lieut. W. E. MILLS, Sumter.

To Camp Jackson, S. C., base hospital, from Camp Dix, Major E. C. MAJOR, Latta.

To Carlisle, Pa., from Camp Dix, Capt. J. A. DILLARD, Columbia.

To Fort Riley, from Camp Travis, Lieut. J. L. BLAIR, Sharon.

South Dakota

To report to the commanding general, Western Department, from San Francisco, Major A. M. GIFFIN, Rapid City.

Tennessee

To Camp Zachary Taylor, Ky., base hospital, from Charleston, Major J. L. MORGAN, Memphis.

To Fort McPherson, Ga., from Charleston, Capt. A. H. MEYER, Memphis.

Texas

To Walter Reed General Hospital, D. C., from Camp Travis, Major A. L. VAN METER.

Vermont

To Boston, Mass., from Camp Dix, Lieut. J. D. THOMAS, Pownal.

Virginia

To Washington, D. C., Surgeon-General's Office, from Roland Park, Major N. ARDAN, Bristol.

Washington

To Camp Jessup, Ga., from Charleston, Major F. J. CULLEN, Napavine.

To Fort D. A. Russell, Wyo., from Camp Lewis, Lieut. H. J. HARDS, Tacoma.

To San Francisco, Calif., Letterman General Hospital, from Camp *Dix*, Capt. J. M. HENDERSON, Seattle.

West Virginia

To Washington, D. C., Surgeon-General's Office, from Fort Adams, Major L. C. COVINGTON, Charleston.

Wisconsin

To Erie Proving Grounds, Ohio, from Camp Custer, Lieut. E. A. LINGER, Oconto.

To Fort Riley, from Camp Grant, Lieut. H. A. VINCENT, Beloit.

ORDERS TO OFFICERS OF THE UNITED STATES PUBLIC HEALTH SERVICE

Asst. Surg.-Gen. C. C. PIERCE, proceed to New York for conference relative to venereal control work and training for nurses.

Surg. E. K. SPRAGUE, relieved at *Portland, Maine, and venereal* disease control work in Boston. *Proceed to marine* hospital and assume charge of the Service.

Surg. H. S. MATHEWSON, relieved at Boston, Mass., proceed to the marine hospital at Vineyard *Haven*, Mass., and assume charge.

Surg. L. D. FRICKS, *relieved at Louisville*, Ky., assume charge of field investigations of malaria. Headquarters *transferred from* New Orleans, La., to Memphis, Tenn.

Surg. W. C. BILLINGS, relieved at San Francisco, Calif, proceed to Alexandria, La., and assume charge of the Public Health Service Hospital.

Surg. W. A. KORN, proceed to Fort Stanton, N. Mex., and assume charge of the station.

Surg. L. P. H. BAHRENBURG, proceed to *Dawson Springs, Ky., for* inspection of location for hospital and sanatorium.

Surg. F. H. McKEON, relieved at Fort Stanton, N. Mex., proceed to Charleston, S. C., and assume charge of the quarantine station.

Surg. A. C. SEELY (Reserve), proceed to various points in the States of Oregon, Washington and *Idaho to attend* meetings of various district and county medical societies.

Passed Asst. Surg. LAWRENCE KOLB, relieved at Ellis *Island*, N. Y., *proceed* to Waukesha, Wis., and assume charge of the Public *Health Service* Hospital.

Passed Asst. Surg. R. A. KEARNY, proceed to New York, to investigate the needs of the Hudson Street Hospital when taken over by the Public Health Service.

Passed Asst. Surg. C. L. WILLIAMS, proceed to New *Orleans on* special temporary duty.

Passed Asst. Surg. J. H. SMITH, proceed to Washington, D. C., for conference relative to venereal disease control work in New Jersey.

Passed Asst. Surg. W. L. TREADWAY, relieved *from* duty in school hygiene. Report to the Chief Medical *Advisor, Bureau of* War Risk Insurance for duty.

Passed Asst. Surg. C. V. AKIN, represent the Service at the Seventh Annual Convention of the Southeastern Sanitary Association at Rome, Ga., on May 12 and 13, 1919.

Passed Asst. Surg. C. H. WARING, *relieved at Newport* News, Va., proceed to Washington, D. C., for conference.

Asst. Surg. M. F. HARALSON, proceed to Newport News and Portsmouth, Va., to inspect extracantonment zone work at those places.

Asst. Surg. J. W. MOUNTAIN, detailed as member of Coast Guard retiring board to meet at Portland, Maine, April 29, 1919.

Acting Asst. Surg. R. H. MAYHEW, proceed to Greenville, S. C., for duty *in the* Public Health Service Hospital.

Assoc. San. Engr. H. H. WAGENHALS, proceed to Brunswick, Ga., for investigation of drainage in connection with malaria conditions.

Asst. San Engr. ARCHIE GORMAN, proceed to Texarkana, Ark., *to investigate* malaria control along railroads.

Asst. San. Engr. A. J. WILLISON, proceed to *Memphis, Tenn*, for conference regarding antimalaria measures.

Scientific Asst. H. S. HUTTON, proceed to Perryville, Md., for duty at the Public Health Service Hospital.

Scientific Asst. HAVARD D MOYER, *proceed* to the marine hospital, Baltimore, Md., for inspection of X-ray *laboratory and* equipment.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

ALABAMA

New State Officers.—The Medical Association of the State of Alabama at its annual meeting, April 17, elected the following officers: president, Dr. James S. McLester, Birmingham; vice presidents, Drs. Henry S. Ward, Birmingham, and Walter S. Britt, Eufaula; secretary, Dr. Henry G. Perry, Montgomery (reelected), and treasurer, Dr. Jacob U. Ray, Woodstock. Features of the session were the unfurling of a service flag containing 600 stars, and a memorial service in honor of those physicians of the state who gave their lives in the service of their country.

DISTRICT OF COLUMBIA

Undue Prevalence of Smallpox.—Health authorities, as well as the populace, are disturbed by the unusual amount of smallpox in Washington during the past few months. Quite recently the situation was made more acute by the discovery of some twenty cases among the pupils of St. Ann's Academy, a private school in the southeastern portion of the city. This circumstance raises the question of the efficacy of the existing vaccination law which makes vaccination a necessary condition for admission to the public schools but does not apply to private schools. The health officer is, of course, authorized to compel vaccination wherever necessary in the presence of a smallpox epidemic, but that officer has announced his intention of seeking an extension of the vaccination law as it affects schoolchildren so that the private schools shall be brought within its scope.

The Medical Society Smoker.—The Medical Society of the District of Columbia held a "Get-Together Smoker" at the Wardman Park Hotel, April 30. The president of the society, Dr. William Gerry Morgan, presided over the assemblage of some 175 members and guests. Dr. John B. Deaver of Philadelphia addressed the gathering, the subject of the scientific portion of his address being "The Importance of the Early Recognition of Diseases of the Biliary Passages." He concluded his address by emphasizing the importance of a strong and representative medical organization at the national capital, particularly having in view the world position Washington is destined to hold; and he urged on the members the duty of supporting the movement for the erection of a permanent home for the society. Drs. E. Y. Davidson, William P. Carr, J. B. Nichols, A. Frances Foye and William Gerry Morgan made short addresses on various phases of the building project, and Dr. Thomas Charles Martin concluded the program with one of his inimitable prose poems, the title of which might be rendered "Cows' Tails and Their Relation to Science and Art." Songs appropriate to the occasion were composed by Dr. John Foote and sung by the assembly.

Sanitary Control of the Milk Supply.—The health officer of the District, being clothed with authority to enforce the various provisions of pure food laws, is responsible for the maintenance of safe and desirable standards of purity and food value in the milk supply of Washington. Inasmuch as practically all the milk that is vended here is produced in the states of Maryland and Virginia, the producers are amenable only to the laws of those states and the requirements of the District of Columbia laws are made applicable by a system of licensing producers disposing of milk through Washington distributors. Licenses are granted on the basis of acceptable farm conditions, good health of the herd, and suitability of the milk based on the findings as to bacterial count and butter fat content. But once licensed, revocation or suspension of the license can be secured by the health officer only by prosecution in court, sustained by necessary laboratory evidence. Meanwhile the poor or dangerous milk may be freely distributed to the unsuspecting public. Because of the numerous instances in which inferior milk has recently been found in the local market, the health officer will make renewed efforts to secure legislation authorizing him to confiscate any milk which is found to be dangerous to the public health. Many aspects of the milk producing industry illustrate the close relation between public hygiene, the economics of husbandry, and the economics of eleemyosynary and similar public institutions. Thus a nearby milk producer, who for a number of years supplied the Walter Reed General Hospital with milk on the basis of an annual contract, has retired from the dairying business and sold off his entire herd, because the commandant of the Walter Reed Hospital has adopted the plan of buying milk on the basis of monthly contracts. No doubt there may be good reasons for this action of the hospital authorities, and the plight of the dairyman in this instance is obvious, but it is highly unfortunate that the local milk supply should lose one of its large tributaries and at the same time should be called on to sustain the milk requirements of such a large institution from the remaining resources.

IDAHO

Personal.—Dr. Tracy R. Mason was reelected mayor of Kellogg, April 22.

Tuberculosis Hospital Commission.—The governor of Idaho has appointed a tuberculosis commission to erect two tuberculosis hospitals in the state and to supervise the work preliminary thereto. The members of the commission are Dr. Floyd G. Wendle, Sand Point; Mr. F. A. Davis, Moscow; Norman B. Adkinson, Pocatello, dean of the department of chemistry of the Idaho Chemical Institute, and Mrs. W. A. Athay, Boise. The legislature appropriated $5,000 for the use of this commission and also authorized a levy of one fourth of a mill on all taxable property in 1919, and one eighth of a mill in 1920, which will raise about $185,000 for the construction and operation of the hospitals.

ILLINOIS

Illegal Practitioner Fined.—Evans Tucker, Peoria, was arrested by the Department of Registration and Education of the State of Illinois for practicing medicine without a license and was fined $25 and costs.

Paris Physician in Springfield.—Dr. Paul E. Davy, Paris, a member of the commission for the prevention of tuberculosis in France, who has been spending six months in the United States studying methods of tuberculosis work, spent April 22 and 23 in Springfield as the guest of Dr. George Thomas Palmer.

Personal.—Dr. Frank P. Norbury, Springfield, who has been serving since August, 1918, as acting medical director of the National Committee for Mental Hygiene in New York City, in the absence of Thomas W. Salmon, Col., M. C., U. S. Army, and Frankwood E. Williams, Major, M. C., U. S. Army, has returned home.

State Society Meeting.—The sixty-ninth annual meeting of the Illinois State Medical Society will be held in Peoria, May 20 to 22, under the presidency of Dr. Edward W. Fiegenbaum, Edwardsville. There will be a symposium on influenzal pneumonia which will be introduced by Surg. Wade H. Frost, of the U. S. P. H. S., and the oration on surgery will be given by Dr. Jabez N. Jackson, Kansas City, Mo.

Chicago

Cook County Hospital Examinations.—The results of this competitive examination, just announced, indicate that Rush Medical College secured thirty-six out of forty-five available appointments; Northwestern University Medical College, five; University of Illinois, three, and Chicago College of Medicine and Surgery, one.

Personal.—Dr. John Dill Robertson has been reappointed commissioner of health.——Donald M. Gallie, Capt., M. C., U. S. Army, who has been on duty for a year in the department of facial surgery at Base Hospital No. 11, Nantes, and American Hospital No. 1, Neuilly, France, has returned from overseas.——Dr. Joseph C. Beck, who has been in charge of the Czecho-Slovac Medical Unit at Cognac, France, returned to Chicago, April 25.——French S. Carey and Stanton A. Friedberg, Majors, M. C., U. S. Army, have returned from service with the American Expeditionary Forces in France.

INDIANA

Health Officers to Meet.—The annual meeting of the health officers' school was held under the auspices of the state board of health at the Claypool Hotel, Indianapolis, May 6 and 7.

Society Asks to Change Name.—The Marion County Society for Prevention of Tuberculosis has asked permission in the circuit court to have its name changed to the Marion County Tuberculosis Association.

License Revoked.—An official report states that the license of Dr. George F. Smith, Bicknell, was revoked, Feb. 26, 1919, by the Indiana State Board of Medical Registration and Examination on the ground of misrepresentation of facts in regard to his high school education at the time he secured his license to practice.

Personal.—Dr. Jacob G. Cox, Kokomo, is reported to be seriously ill in a hospital in Cincinnati.——Dr. Lewis N. Geisinger, Auburn, has been elected vice president of the De Kalb County Health and Anti-Tuberculosis Society.——Dr. George E. Lowe, Indianapolis, was severely bruised, April 16, in a collision between automobiles, in which his car was wrecked.——Dr. George V. Cring, Portland, has been appointed health commissioner of Jay County to fill the unexpired term caused by the resignation of Dr. Grant Chaney.

IOWA

Hospital Item.—The new psychopathic hospital, for which an appropriation of $175,000 was made by the last legislature, will be erected on the new University of Iowa campus, Iowa City, west of the new Children's Hospital.——Dr. Willard T. Graham, superintendent of the Iowa Hospital, Iowa City, has decided that adult cripples entitled to treatment at state expense, under the extension of the Perkins law, may be accommodated at the institution.——Mercy Hospital, Davenport, has had plans completed for a new nurses' home to cost $100,000.

Personal.—Dr. J. Fred Clarke, Lieut.-Col., M. C., U. S. Army, Fairfield, commanding Hospital Unit R, which has been overseas for sixteen months, returned home, April 26.——Dr. Mary K. Heard, Iowa City, has been appointed traveling representative of the Y. W. C. A. for Iowa, Nebraska, Wisconsin and the Dakotas.——Dr. George M. Middleton was reappointed city physician of Davenport, April 15.——Dr. Winfield S. Devine, Marshalltown, who was operated on at Rochester, Minn., April 12, for disease of the kidney, is reported to be improving.——Dr. Frank C. Roberts, Fort Madison, has been reappointed a member of the insane commission of Lee County.——Dr. Oscar A. Dahms has been reelected a member of the board of directors of the public schools of Davenport, and Dr. Karl Vollmer has been reelected president of the board.——After being out only thirty minutes, the jury in the case of Dr. Charles A. Snyder, Dubuque, charged with the murder of Mrs. Florence Gagne of East Dubuque, Ill., by the performance of an illegal operation, found Dr. Snyder not guilty.

LOUISIANA

New Officers.—The fortieth annual convention of the Louisiana State Medical Association was held in Shreveport, April 7 to 10, under the presidency of Dr. Wilkes H. Knolle, New Orleans. Dr. Amedee Granger, New Orleans, was elected president, and Dr. Sidney C. Barrow, Shreveport, secretary-treasurer.

New Orleans Inaugurates a Systematic Hay-Fever Campaign.—Three years ago, through the efforts of the New Orleans section of the American Hay-Fever-Prevention Association, an ordinance was passed by the commission council for the control of hay-fever weeds in that city. Although this was beneficial to some extent, it lacked efficiency, as in many cases, persons preferred the fine to paying a larger cost for cutting the weeds. In order to improve its efficiency, this ordinance was amended last year, authorizing the city to cut the weeds after due notice to the property owner. This method, which was instituted by the American Hay-Fever Prevention Association and which is recommended for other cities, is proving efficient to the public from a sanitary standpoint, as well as from an economical standpoint. It is expected to result in a still lower rate in the number of hay-fever cases in New Orleans.——Announcement was made by the Charity Hospital, New Orleans, April 17, that the hay-fever department would resume its semiweekly clinics on Tuesdays and Thursdays which will be continued until the end of the hay-fever season in November.

MARYLAND

Appointments.—The Baltimore City Health Department has made the following appointments: Dr. Wright S. Sudler, health warden for the twenty-sixth ward; Dr. Leon S. Horka, health warden for the twenty-fifth ward, and Drs. Joseph T. Nelson, Bernard V. Kelly and Jay T. Hennessey, throat inspectors for the health department.

Hospital Offers Clinic.—An offer from the South Baltimore General Hospital to establish a maternity clinic without cost to the city was made to the board of estimates recently and has been accepted. Health Commissioner John D. Blake, Baltimore, was authorized to appoint a physician to take charge of the clinic, which is to be maintained in connection with the Bureau of Child Hygiene and Infant Mortality. The clinic is to be for the women of South Baltimore, including those living in the Brooklyn and Curtis Bay sections.

Personal. — Samuel J. Fort, major, M. C., U. S. Army, Catonsville, one of the fifty-four expert rifle and pistol shots selected to form the instructional personnel of the Small Arms Firing School at Camp Perry, Ohio, and later one of six officers detailed from the school to assist in training the Nineteenth Division at Camp Dodge, Iowa, has been discharged from the Army and is now visiting at Catonsville.——Dr. Charles H. Latimer, Laurel, assistant physician at the Laurel Sanitarium, is accompanying a member of the Swiss legation to his home in Geneva, Switzerland.

To Study Tuberculosis.—The National Association for the Study of Tuberculosis has recently granted $10,000 for an exhaustive scientific study to be made in Baltimore of the underlying causes of tuberculosis, under the direction of a committee consisting of Dr. Henry Barton Jacobs, Baltimore, president of the Maryland Association for the Study and Prevention of Tuberculosis; Dr. Raymond Pearl, professor of biometry and vital statistics in the School of Hygiene and Public Health, Johns Hopkins University, and Dr. William T. Howard, Baltimore, assistant commissioner of health. The grant is intended to defray the expenses of the investigation and study for a year and the start will be made as soon as the necessary force of investigators can be organized. Baltimore city makes an annual appropriation of $30,000 to the health department for its tuberculosis work, and yet little progress has been made toward the reduction of the death rate. This is because the department has been unable to make its investigation as far reaching and as effective as the officials in charge have felt that the situation demanded.

MASSACHUSETTS

Charged with Illegal Practice.—David J. Khoury, Lawrence, is said to have been summoned before the local board of health, April 2, charged with the illegal practice of medicine.

Hospital for Women.—A new women's hospital with accommodation for 150 women and girls is to be established in Boston by the Salvation Army. The institution will be largely given over to maternity work.

Public Health Nursing Subdivision Created.—The Massachusetts State Department of Health announces that a subdivision of public health nursing has been created within the division of hygiene. This will include the health instructor nurses of the division of hygiene. Miss Blanche Wildes, one of the present health instructors, has been appointed chief of this division.

Personal.—Edwin M. Kent, Boston, has been appointed supervisor of mouth hygiene in the division of hygiene of the state department of health. His work will have to do with the preparation of educational material on mouth hygiene and gathering and correlating information regardig dental dispensaries in the state.——Miss Bernice W. Billings, chief of the subdivision of tuberculosis in the division of communicable diseases in the state department of health, has resigned to accept a position as executive secretary of the Oneida County (N. Y.) Tuberculosis Committee.——Dr. George Thomas Tuttle, after forty years' association with the McLean Hospital, Waverly, the greater part of this time as superintendent of the institution, has resigned. He has been elected a member of the board of trustees of the Massachusetts General Hospital.—Harvey Cushing, Lieut.-Col., M. C., U. S. Army, in command of Base Hospital No. 5, reached New York, April 22.——Dr. Harold W. Hersey, Winchester, assistant superintendent of the Massachusetts General Hospital, Boston, has been elected superintendent of the Macon (Ga.) Hospital.——Dr. Lee Sutton has been appointed special pathologist in the Boston City Hospital.

MICHIGAN

Alumni Clinic.—The thirtieth annual clinic of the Alumni Association of Detroit College of Medicine and Surgery will be held in Detroit May 13 to 20.

Medical Officers May Borrow from Society.—It is announced that members of the Wayne County Medical Society who have returned from war service may borrow up to $300 to reestablish themselves in practice. The funds will be loaned on notes bearing interest at 4 per cent.

Health Board Act Passed.—An act abolishing the present state board of health and putting in its place an advisory council of health was passed by the senate, April 15, by a vote of 23 to 5. In its final form the bill creates a state health commissioner to be appointed by the governor, and an advisory council of health of five members also to be appointed by the governor.

Personal.—Dr. Arthur J. Carlson, for four years health officer of Escanaba, has resigned.——Dr. Francis Duffield has been appointed president of the board of health of Detroit. ——Dr. Fred N. Bonine has been reelected mayor of Niles. ——Drs. Harry B. Knapp, Battle Creek, and D. M. Morril, Houghton, have become members of the staff of the Copper Range Hospital, Trimountain.

MINNESOTA

Southern Minnesota Medical Meeting.—The midsummer meeting of the Southern Minnesota Medical Association will be held at Rochester, June 30 and July 1.

Resignation Not Accepted.—After an executive session of the state board of health, April 29, it is announced that the board by unanimous vote refused to accept the resignation of Dr. Henry M. Bracken, secretary of the board, which had been demanded by the senate, April 21.

Personal.—Dr. Cora Hulda S. Allen, Heron Lake, has returned after a year in Red Cross service in Paris.——Dr. Milo E. Bushey, Arlington, has been elected secretary of the Sibley County Public Health Association.——Dr. Albert J. Chesley, Minneapolis, who served for six months in France, and then was ordered to duty in Poland, has been appointed head of the public health work with the Polish forces.—— Dr. Frederick Barrett has been elected mayor of Gilbert.—— Dr. John E. Campbell has been appointed city physician of St. Paul.

MONTANA

Personal.—Dr. Clarence J. Munch, Culbertson, has been appointed physician of Sheridan County.——Dr. Herbert H. Judd has been appointed health officer of Bozeman and Gallatin counties.——Dr. Charles E. K. Vidal, Great Falls, has been appointed superintendent of the State Tuberculosis Sanatorium at Galen, succeeding Dr. Alexander D. MacDonald, deceased.

New State Board Officers.—At the annual meeting of the state board of health in Helena, April 7, Dr. Daniel J. Donohue, Butte, was elected president, Dr. Louis H. Fligman, Helena, vice president, and Dr. William F. Cogswell, secretary (reelected). Dr. John J. Sippy, Topeka, state epidemiologist of Kansas for six years, was appointed to a similar position in Montana.

NEW YORK

Reconstruction Committee Favors Health Insurance.—The governor's reconstruction commission has adopted a report favoring compulsory health insurance for industrial workers "as a measure of essential and enforcible health protection." Hearings on the question have been under way for some time and have been attended by leading civic workers and insurance authorities. The investigation is to be continued with a view to preparing a bill that will meet all contingencies.

New York City

Dues of Members in Service Remitted.—The Comitia Minora of the Medical Society of the County of New York has passed resolutions empowering the treasurer to remit the dues of members in service who so request. Such requests must be filled at once so that the books of the society may be brought up to date.

Personal.—Dr. Joseph A. Blake, who had charge of an American Ambulance at Neuilly, and later of a hospital of his own at Ris Orange, France, under the British Red Cross, has returned to this country.——Dr. Elbert M. Somers, Brooklyn, has completed his service with the American Red Cross as hospital superintendent in France.

New Site for Orphan Asylum.—A new site for the Hebrew Orphan Asylum, comprising 103 acres on Two Hundred and Thirty-Third Street in the Bronx, has been purchased for $350,000. It is planned to erect new buildings at a cost of about $1,000,000. The cottage system is favored, with separate buildings for hospital, dispensary and schools.

Association for Study of Exceptional Children.—The National Association for the Study and Education of Exceptional Children held its annual meeting and dinner at the Hotel McAlpin, April 30. Among the speakers were Dr. Frederick J. Farnell of Providence, R. I.; Dr. E. Bosworth McCready, Pittsburgh; Dr. Francis N. Maxfield of Newark, N. J.; Dr. Ira S Wile of New York City, and Health Commissioner Royal S. Copeland

Red Cross to Teach Home Nursing.—The American Red Cross has rented an apartment in a tenement house at 510 West Twenty-Sixth Street where it will teach elementary hygiene and home nursing to tenement dwellers in that locality. If the experiment is successful similar centers will be established in other parts of the city. The enterprise is receiving the cooperation of Health Commissioner Royal S. Copeland and Dr. John Lovejoy Elliott.

OHIO

Honor Senior Physicians.—In honor of the four oldest practitioners of Allen County, a dinner was given at Lima, April 15, by the Allen County Medical Society. The guests of honor were Drs. Jonathan B. Vail and Enos G. Burton, Lima, Newton Sager, Lafayette, and Salathiel A. Hitchcock, Elida.

State Medical Board.—The personnel of the state medical board of Ohio is at present: Dr. Benjamin R. McClellan, Xenia, president; Dr. Charles E. Sawyer, Marion, vice president; Dr. Herbert M. Platter, Columbus, secretary; Dr. Sylvester M. Sherman, Columbus, treasurer, and Drs. John H. J. Upham, Columbus, Lee Humphrey, Malta, Lester E. Siemon, Cleveland, and John K. Scudder, Cincinnati.

Venereal Disease Clinics.—During March nearly 800 persons with venereal diseases were treated in clinics maintained under the supervision of the state department of health, the increase over the figures for February being 250. Clinics were opened in nine cities in March and arrangements have been completed for the immediate establishment in six additional cities. The work of these clinics is being supplemented by educational work and measures for the repressing of vice. Provision is also made for the quarantining of persons whose habits make them a menace to the public health.

Personal.—Dr. William Roehn, who was recently discharged from military service, has been reappointed jail physician at Dayton.——Dr. James B. Hall, Mansfield, suffered a cerebral hemorrhage, April 13, and is reported to be in a critical condition.——Dr. Otto Mueller, Cleveland, was shot through the abdomen, April 15, by a sanitary policeman whose wife had been under Dr. Mueller's care. ——Willard C. Stoner, Lieut.-Col., M. C., U S. Army, Cleveland, commander of Evacuation Hospital No. 3, Treves, Germany, who went overseas with Base Hospital No. 52, in July, 1918, arrived in America, April 4.

Special Course of Instruction for Physicians.—A special course for physicians will be held at the Ohio State Sanatorium, Mount Vernon, from June 24 to June 27. The course has been suggested by Dr. Edward G. Reinert, Columbus, and arranged by Dr. Stephen A. Douglass, Mount Vernon, superintendent of the sanatorium, and includes a course of ten lectures and clinics, including the history of tuberculosis; anatomy and histology of the lungs, physiology of respiration; pathology of pulmonary tuberculosis; modes of infection; theory of child infection; heredity; symptomatology; diagnosis; treatment; differential diagnosis; tuberculosis of children; sociological factors, and prophylaxis. Physicians interested in this course should communicate with Dr. Stephen A. Douglass, superintendent of the Ohio State Tuberculosis Sanatorium, Mount Vernon.

OKLAHOMA

Hospital Standardization.—A meeting has been called at Muskogee for May 21, for the purpose of organizing a state hospital association. One of the prime objects of this organization will be the standardization of hospitals in the state.

Personal.—Dr. John W. Duke, Guthrie, state commissioner of health, has resigned and Dr. Arthur R. Lewis, Ryan, has been appointed his successor.——Dr. Benjamin T. Bitting has been appointed medical superintendent of the State Institution for the Feebleminded, Enid.

Sanatorium Bill Passed.—The last official act of the seventh legislature of Oklahoma was to pass the sanatorium bill which has been fostered by the Oklahoma Tuberculosis Association. The bill provides for two sanatoriums for white persons and one sanatorium for negroes. The appropriation for the former institution is $200,000 and $50,000 for the negro institution, and an additional appropriation of $100,000 was made for maintenance for the coming biennium. The bill also provides for the creation of a bureau of tuberculosis in the state department of health under a chief who will have a salary of $3,000. Each county is authorized to levy a special tax, not exceeding 1 mill, for a tuberculosis fund, and from this levy a large part of the cost of maintenance of the sanatoriums will be derived. The superintendent of each district sanatorium is authorized to establish tuberculosis dispensaries in his district and to employ at least one public health nurse on his staff.

PENNSYLVANIA

State Will Abandon Quarantine Station.—State quarantine service, for years operated at Marcus Hook, will be discontinued June 1. This announcement was made in Harrisburg by Governor Sproul. The federal government will take over the entire quarantine service, thus saving a double inspection of ships before they reach the port of Philadelphia. This change will save the state at least $50,000 a year.

Personal.—Dr. Jacob W. E. Ellenberger, Wilkinsburg, has been appointed acting medical inspector in place of Dr. Adolph Koenig, Pittsburgh, resigned.——Dr. Cornelius C. Wholey, Pittsburgh, who has been psychiatrist to the United States General Hospital at Roland Park, Md., since December, 1918, has returned home.——Joel T. Boone, M. C., U. S. Navy, Pottsville, has been awarded the Croix de Guerre with palm for bravery under fire at Rheims last October.

Philadelphia

Personal.—Ernest LaPlace, Lieut.-Col., M. C., U. S. Army, who has been in command of the post hospital at Fortress Monroe and of the medical stations and coast defense of Chesapeake Bay, has obtained his discharge and has returned to his home.——William M. Late Coplin, Lieut.-Col., M. C., U. S. Army, was recently discharged from Camp Dix, after ten months' service with the American Expeditionary Forces in France and Germany.——Robert G. LeConte, Lieut.-Col., M. C., U. S. Army, has been made a chevalier of the Legion of Honor. Colonel LeConte was attached for some time to the staff of the Pennsylvania Hospital, but went to France with the Methodist Hospital Unit and was naval consultant for Pershing's forces.

Public Health Day.—Wednesday, April 30, was celebrated as Public Health Day and a program was arranged under the auspices of the Department of Health and Charities, Babies' Welfare Association, College of Physicians, City Club, Board of Public Education, Civic Club, Housing Association, Philadelphia County Medical Association, Children's Playground Association, Pennsylvania Society for the Prevention of Tuberculosis, City Parks Association, and Child Federation. At the morning exercises addresses were delivered at all the high schools on matters dealing with personal hygiene and promotion of public health. A long table luncheon was held at the City Club at 12:30 and Dr. Wilmer Krusen, director of public health and charities, and Dr. John D. McLean, assistant commissioner of health, state of Pennsylvania, were the speakers. In the evening a mass meeting was held in the auditorium of the William Penn High School at which Dr. James M. Anders presided.

Hospital Units Return.—The Jefferson Hospital Unit known as Base Hospital No. 38, and the Pennsylvania Base Hospital, known as No. 20, arrived in New York, April 28. Some officers of both units returned home several weeks before, and some of the nurses are still in France, having been transferred to other hospitals. John B. Carnet, Lieut.-Col., M. C., U. S. Army, commander of Base Hospital No. 20, returned home ten days before. Base Hospital No. 20 had been at Chatel Guyon and during the course of their stay they administered to approximately 1,000 sick and wounded and only fifty deaths were reported. While the Chateau Thierry and Argonne drives were in progress, they were taxed to the limit, as the personnel was decreased in order to provide mobile teams to go to these fronts. Base Hospital No. 38, stationed at Nantes, took care of more than 9,000 patients and had a capacity of treating 1,000 patients daily. When the armistice was signed, ten medical officers, thirty-six nurses and 100 men were caring for 2,400 sick and wounded.

SOUTH CAROLINA

New State Board Members.—The following have been selected as members of the State Board of Medical Examiners: Joseph T. Tayer, Adams Run, first district; Frank M. Lander, Williamston, third district; Baxter M. Haynes, Spartanburg, fourth district; J. R. Hill, fifth district, and Julius H. Taylor, seventh district.

New Officers.—At the seventy-first annual meeting of the South Carolina Medical Association, held April 15 and 16, the following officers were elected: president, Dr. Ebenezer W. Pressly, Clover; vice presidents, Drs. Dudley H. Smith, Florence, Charles A. Mobley, Rock Hill, and Linnaeus C. Shecut, Orangeburg, and secretary-treasurer, Dr. Edgar A. Hines, Seneca (reelected). Greenville was selected as the next place of meeting.

VERMONT

New Laws for Medical Education and Public Health.—The legislature of Vermont has passed the following bills relating to medical education and public health:

No. 166, which provides that the State Board of Medical Registration may, at such time as it deems expedient, require of all applicants for examination to practice medicine and surgery a certificate that they have had a one year's internship in a hospital approved by the board.

No. 167, amending Section 6091 of the general laws relating to the standard of requirement for admission to practice medicine and surgery so as to require two college years of preliminary education for medical students.

No. 168, amending Sections 6093, 6094, and 6095 of the general laws regarding the practice of medicine, surgery, osteopathy, and chiropractic, which provides that "A person who, not being licensed, advertises or holds himself out to the public as described in the following section, or who, not being licensed, practices medicine or surgery, or who practices medicine or surgery under a fictitious or assumed name, or who impersonates another practitioner or signs a certificate of death for the purpose of burial or removal, shall be imprisoned not more than three months or fined not more than two hundred dollars or both." This also defines the practice of medicine.

No. 169 bringing all medical practitioners under the provisions of the section for revoking of licenses for cause.

No. 170 which amends Section 6100 of the general laws relating to the qualifications of the practitioners of osteopathy raises the qualifications for osteopaths from three years of nine months each to four years of nine months each.

No. 172 an act to regulate the practice of chiropractic which provides for the appointment of an examination board of three members who shall be chiropractors. The requirements for licenses shall be satisfactory evidence of a high school education or its equivalent, applicants shall be at least twenty-one years of age, of good moral character and graduates of a reputable school of chiropractic requiring three years' resident studentship, payment of $25 to the treasurer of the board, and the successful passing of the examination in anatomy, physiology, symptomatology, hygiene, chiropractic orthopedy, histology, pathology, neurology and principles of chiropractic and clinical demonstration of vertebral palpation, nerve tracing and adjusting, and such other subjects as the board may prescribe.

No. 175 authorized the State Board of Health to appoint district health officers in place of town health officers and specifies their duties.

No. 176, which provides that the director of state institutions may with the approval of the board of control, designate or construct a ward or hospital at any state institution for the purpose of giving necessary treatment and care to inmates of such institutions, as may be afflicted with tuberculosis, or other contagious or venereal disease.

No. 177, amending Section 6250 of the general laws and provide for the reporting of venereal diseases for the entering of sale of drugs by physicians and for the treatment of venereal diseases, and for the reporting by druggists of the sale of medicine for use in the treatment of venereal disease.

No. 178, amending Section 6252 of the general laws and whereby the state provides for facilities for the free laboratory examination of material from suspected cases of venereal diseases and the furnishing of specific treatment at cost or free to clinic patients.

No. 179, which amends Section 6253 and deals with the confidential nature of the reporting or information leading to reports in connection with persons suffering from venereal diseases, and section 7035, which provides penalty or imprisonment of not less than two years, or fines of not less than $500 in cases of marriage of the person who has been afflicted with venereal disease unless certified to have been cured by a legally qualified practitioner; Section 7036 provides a sentence of imprisonment for not less than two years, or fines of not less than $500 for any person who, while suffering from venereal disease, has sexual intercourse.

No. 180 sets aside a sum of $10,000 from the money annually appropriated to the State Board of Health to be expended for the purpose of rural sanitation in order to take advantage of any appropriation from the Federal Government that may become available by the state.

WASHINGTON

Personal.—Ralph Hendricks, Major, M. C., U. S. Army, has been appointed city health officer of Spokane.——Dr. James E. Crichton has been elected president of the Seattle Anti-Tuberculosis League.——A farewell reception was given to Dr. and Mrs. John B. Anderson, Spokane, by the employees of the city health office and members of the Rivercrest Contagion Hospital, April 18. Dr. Anderson is retiring as city health officer after eight years of service to become state commissioner of health. A gold badge bearing the insignia of his new office was presented to Dr. Anderson, Dr. John R. Neely, Spokane, making the presentation speech.——A luncheon was given at Spokane, April 22, in honor of Dr. Herbert E. Wheeler, Spokane, who has just returned after war service abroad.——Dr. Wilbur N. Hunt, Burlington, has succeeded Dr. Francis B. West, Mount Vernon, resigned, as physician of Skagit County.——Dr. Mabel Seagrave, Seattle, has returned after nearly a year of service overseas.——Dr. John W. Mowell, Olympia, chief surgeon of the Industrial Insurance Company, will retire from that office in June, to become a member of the new Safety First Commission and will be succeeded as chief surgeon by Dr. Floyd A. Bird, Kelso.——Dr. Thomas D. Tuttle, health officer of Seattle, has been appointed state epidemiologist of Kansas.——Dr. Hiram M. Read has succeeded Dr. John S. McBride as health commissioner of Seattle.——Samuel E. Lambert, Spokane, Lieut.-Col., M. C., U. S. Army, who recently returned from overseas duty with the Spokane Hospital Unit, has been appointed post surgeon at Fort George Wright, Spokane.——Dr. John Reith, College Place, for seven years superintendent of the Walla-Walla Sanatorium, is about to leave for England, en route to Capetown, South Africa, where he will take charge of a hospital.

WEST VIRGINIA

State Association Meeting.—The annual meeting of the West Virginia State Medical Association will be held at Clarksburg, May 20 to 22.

Examination to Be Held.—Dr. Samuel L. Jepson, Charleston, commissioner of the board of health of the state, announces that the next examination of the West Virginia Public Health Council will be held at the Hotel Huntington, Huntington, July 8 to 10.

Personal.—Dr. Carl F. Raver has been appointed epidemiologist of the state board of health of West Virginia.——Dr. Frank H. Ikirt has been appointed jail physician of Wheeling, succeeding Dr. Harry P. Campbell.——Dr. John W. Kidd, Burnsville, who has been seriously ill, is reported to be convalescent.

CANADA

Addresses in Medicine and Obstetrics.—Sir St. Clair Thompson, London, England, is to deliver the address in medicine at the annual meeting of the Ontario Medical Association in Toronto, May 28, taking for his subject: "Shakespeare as an Aid in the Art and Practice of Medicine;" Dr. J. Morris Slemons, professor of obstetrics and gynecology in Yale University, New Haven, Conn., will deliver the address in obstetrics.

Queen's University Receives Endowment.—Queen's University, Kingston, Ontario, reports that an additional endowment of $1,000,000 has been received for the general purposes of the university. The medical faculty will benefit from this fund in proportion to its requirements, and it is proposed that several more full-time professors will be secured and the departments of physiology, bacteriology and public health will be developed. A fund of $200,000 is also available to be expended in the reconstruction of the hospital.

Public Health in Ontario.—Under the Venereal Act it is not being found that gonorrhea and syphilis is such a menace as some would have the people of the province believe. In March there were only ninety-seven cases of syphilis reported for the whole province; 183 of gonorrhea; chancroid, four; in April, 110 cases of syphilis, 139 of gonorrhea and three of chancroid. There were 137 deaths from influenza in April, and 341 from pneumonia. The total deaths from all causes were 2,510. During the month the Ontario Board of Health distributed 21,557,000 units of antitoxin to places where diphtheria existed.

Personal.—Dr. Alexander McPhedran, Toronto, has resigned the professorship of medicine in the University of Toronto medical department, and Dr. Duncan A. L. Graham has been appointed his successor. Recently Sir William Osler invited professors of medicine in the United Kingdom to a dinner in Dr. Graham's honor, at which it was stated that Dr. Graham was the first whole-time professor of medicine appointed in the British empire. The appointment was made possible by the munificence of Sir John Eaton, Toronto. As a result all physicians in the service of the medical department at the university will resign, so that Dr. Graham will have a free hand in selecting his own staff.——Dr. Archibald P. Knight, for twenty-seven years professor of physiology in Queen's University, Kingston, Ontario, will, it is said, shortly tender his resignation, but will retain his position until a successor is appointed.

LATIN AMERICA

National Medical Congress of Colombia.—The *Repertorio* of Bogotá recalls that the Fourth National Medical Congress of Colombia is to convene at Tunja, August 7, of the current year. The registration fee of $5 is to be sent to Dr. J. Del C. Cárdenas, Bogotá, Colombia.

Prohibition in Mexico.—It is reported from Mexico that the National Board of Health, presided over by Dr. J. M. Rodriguez, has prepared and submitted for consideration by the national government a bill which will result in the enforcement of absolute prohibition in Mexico. In the opinion of the board, alcoholism is a national affliction which should be combated by every possible means.

National Medical Congress of Venezuela.—A Venezuela exchange states that the Third Venezuelan Congress of Medicine has been postponed to July 5, 1921, centennial of the date of the battle which decided the independence of Venezuela. The committee of organization announces that the medical geography of the country is the main topic for discussion. This includes the study of malaria, beriberi, yellow fever and the medical flora of the country.

The Amazonas Medical Association.—The foundation of the Sociedade de Medicina e Cirurgia do Amazonas dates from early in 1917. There were about twenty-four charter members, and meetings have been held regularly nearly every month since, at Manaos. The first president was Dr. J. M. Leão. The officers for the current year are Dr. A. A. da Matta, president; Dr. J. M. Leão, vice president; Dr. J. Linhares de Albuquerque and Dr. F. M. Vidal, first and second secretary, and Dr. E. Duarte, treasurer. There are five committees, including the one with five members which publishes the *Amazonas Medico,* the quarterly issued by the society. All communications for the editors should be sent to Dr. A. A. da Matta, Caixa postal 40 Manaos. It is announced that every published work sent to them will be listed and reviewed.

GENERAL

National Tuberculosis Association Meeting.—The fifteenth annual meeting of the National Tuberculosis Association will be held in Atlantic City, N. J., June 14 to 17, under the presidency of Dr. David R. Lyman, New Haven, Conn. On the first day the chief topic for discussion will be "What Is the Future of the Tuberculosis Movement: Shall it Remain Specialized or Merged with Other Health Agencies." On June 16, there will be symposiums on "What Has More Centralized Control to Offer in Solving the Tuberculosis Problem?" and "The Discharged Tuberculous Soldiers." During the session of the last day, the principal topics for discussion will be "Removal and Relief of Poverty as Factors in the Prevention of Tuberculosis"; "The Schedule of Tuberculosis Work for the Public Health Nurse," and "The Classification and Standardization of Tuberculosis Sanatoriums and Hospitals."

Attempts to Secure a Medical Diploma.—The dean of the University of Minnesota Medical School reports that an individual calling himself William C. Carroll sent in an affidavit issued in Harris County, Texas, stating that a diploma he says he received from the University of Minnesota had been destroyed by fire and asked to have a copy sent to him at 15 Newhall Street, Lynn, Mass. He also claims in another affidavit to have finished a course at the Mayo Clinic in 1915 and in that affidavit refers also to the destruction of his diploma. The report states that the Dr. William C. Carroll, who is the rightful owner of the diploma issued by the University of Minnesota Medical School, is still living in St. Paul. He states that this other "William C. Carroll" is evidently a fraud who is attempting in this manner to secure a diploma. Secretaries of state licensing boards are urged to be on the lookout for this individual.

Bequests and Donations.—The following bequests and donations have recently been announced:

Methodist Hospital, Philadelphia, $25,000 by the will of Henry H. Morrison on the death of two persons who have life interest in the estate.

Peter Bent Brigham Hospital, Boston, $10,000 for the establishment of a free bed, and at the termination of a trust fund created for benefit of Mr. Cochrane's family, the principal of the trust to Harvard College, by the will of Alexander Cochrane, Boston.

Leland Stanford, Jr., University Medical School, San Francisco, a donation of $12,000 for the purchase of one gram of radium to be used in connection with the actinographic department of the Stanford University Hospital, San Francisco, by Mr. and Mrs. William Fitzhugh. The income of this fund is to be used for beds for indigent patients, particularly for those who need roentgen-ray or radium treatment.

Vanderbilt Clinic of the College of Physicians and Surgeons in the City of New York, and Presbyterian Hospital Tuberculosis Clinic, New York City, each $8,500; Loomis (N. Y.) Sanatorium, and Trudeau Sanatorium, Saranac Lake, N. Y., each $3,000; New York Association for Improving the Condition of the Poor and Home Hospital, New York City, each $2,500; Stony Wold Sanatorium, Lake Kushaqua, N. Y., $2,000; Hospital and Home of Rest for Consumptives, Inwood, N. Y., $1,000, and Henry Street Settlement for Tuberculosis Nursing, $500. Donations were by the trustees of the East River Homes Foundation, New York City.

Ophthalmic Examinations.—The American Board for Ophthalmic Examinations will conduct its fifth examination at the Wills Eye Hospital, Philadelphia., June 6 and 7. The board is composed of representatives of the American Ophthalmological Society, the Section on Ophthalmology of the American Medical Association, and the Academy of Ophthalmology and Oto-Laryngology. For a certificate of this board, the examination in ophthalmology consists of case records, written examinations, and clinical laboratory and oral examinations, or so much thereof as may be judged necessary. Candidates in ophthalmology are required to submit twenty-five complete case records of which not more than ten should be descriptive of operations. These records should be of cases of ocular diseases and defects of varied character, including errors of refraction or muscle balance; external ocular diseases or diseases of the uveal tract or retina, or of the optic nerve, or glaucoma. The reports should show especially the reasons for the diagnosis, and for the operative treatment and the technic of operations in operative cases. The written examination will test the candidate's knowledge of the underlying principles of the science of ophthalmology, including anatomy, embryology, physiology, physiologic optics, pathology, relations of the eye to the other organs and diseases of the body. The oral examination will include: the external examination of the eye; ophthalmoscopy (candidates are requested to bring their own ophthalmoscopes); measurements of errors of refraction; testing of the ocular movements and fields of vision; relations of ocular conditions to diseases of other parts of the body and their treatment, and laboratory examination in histology, pathology and bacteriology of the eye. Further information may be had on request from the Secretary, Dr. William H. Wilder, 122 South Michigan Avenue, Chicago.

FOREIGN

Tuberculosis Course in Spain.—On the initiative of Dr. Verdes Montenegro, steps are being taken to establish a course in tuberculosis in the medical school of the University of Madrid.

Honorary Medical Degree Given Red Cross Director.—The University of Liege, Belgium, April 28, conferred the honorary degree of Doctor of Medicine on G. Johan Van Schott, Jr., Washington, D. C., American Red Cross commissioner for Belgium, in recognition of his services in Belgian hospitals during the war.

Tuberculosis in Austrian Prisons.—Speaking before the Massachusetts Anti-Tuberculosis League in Boston, April 23, Seymour H. Stone, secretary of the Boston Tuberculosis Association, and who has been in charge of Red Cross work in the Province of Genoa, Italy, declared that between 40,000 and 60,000 soldiers have contracted tuberculosis in Austrian prisons.

Tragic Death of Doederlein.—According to a cable dispatch, Prof. Albert Doederlein was among the hostages said to have been shot in Munich during recent political disturbances. Doederlein has been professor of obstetrics and gynecology at the University of Tübingen since 1897. Before that he served for a time at the University of Groningen in Holland. He has written much on puerperal fever and on various gynecologic surgical subjects. He had not quite reached his sixtieth year.

Navy Aids Red Cross Work.—Six submarine chasers have been placed at the disposal of the American Red Cross by the Navy for the transfer of personnel and supplies to the various islands in the Grecian Archipelago where the work of the Red Cross has been begun and is rapidly increasing. ——King Alexander of Greece, April 9, received Lieut.-Col. W. Anderson, member of the American Red Cross Commission to the Balkans, and his staff, and Lieut.-Col. Edward Capps, director of the American Red Cross in Greece, and expressed his appreciation of the work done by the American Red Cross in Macedonia, and of the efforts of the physicians and nurses in checking the ravaging of typhus in Macedonia and the islands of the Grecian Archipelago.

MEXICO LETTER

Mexico City, April 29, 1919.

A Pasteur Institute at Managua

Having the desire of establishing a Pasteur Institute, the government of Nicaragua has asked the Mexican government to send, at the expense of the former, a person to establish it. In compliance with this request, the Mexican authorities have intrusted Dr. G. Leal with this duty, and he will depart shortly with the necessary personnel and equipment. As a courtesy to a sister republic, the Mexican government will bear the expenses connected with the trip.

Intellectual Interrelations

Mention has been made at different times in these letters from Mexico of the more or less serious plans to establish an exchange of professors and students between Mexico and the United States, and I have expressed regrets that nothing concrete came out of such plans. It seems that something definite, however, will at last be accomplished in this direction, for the University of Washington has submitted plans for a proposed exchange with the University of Mexico. This will begin by sending a Mexican professor to Seattle to begin his course Jan. 2, 1920, and end it September 30, devoting the other three months to giving conferences on Mexican civilization, history, and customs in the states of Washington, Montana, Idaho and Oregon. This professor should, of course, know English, and would be accompanied by as many students of both sexes as might be determined by the University authorities of Mexico. The American professor would arrive at Mexico before February 7, when his course would begin, ending in October, and he would devote the rest of the year in visiting the universities of the states of Puebla, Jalisco, and Michoacán, in which he will give conferences in Spanish on American subjects. The expenses of this exchange of professors would be borne by the respective universities.

Commission for the Study of Typhus

In accordance with the resolutions adopted by the Congress on Typhus Fever, held last January, there has just been organized in this city a central commission for the study of typhus fever. The commission will have for its object to initiate, direct and advance the investigations made in this country on typhus (*tabardillo*), and it is preparing a general program for both clinical and experimental work which, it is believed, will result in yielding at an early date satisfactory information on the cause and treatment of typhus fever, and of the preventive measures which should be enforced against this disease. The commission has requested the assistance of the public health and political authorities, the medical profession, scientific associations, and the people in general, since the work is of general interest. The chairman of the commission is Dr. D. José Terrés, and the secretary Dr. D. Alfonso Pruneda, whose address is : 1/a. del Alamo, no. 14.

International Congresses

The Congreso de Americanistas, which was going to meet in Rio de Janeiro next June, has been postponed until the year 1920.

Antialcoholic Campaign

There has just been founded a league called "Asociación Anti-alcohólica Nacional," having for its object a campaign against alcoholism. The league will oppose the transfer of American distilleries to Mexico. They say that in the border towns the traffic in spirituous liquors is on the increase, since those who cannot get them in Texas have only to cross the border to supply themselves in Mexican territory.

Personal

Dr. R. Raygadas will soon leave for the city of Berne to represent the Mexican Red Cross at the International meeting which will be held there after peace is signed.

Dr. G. Gómez has been elected president of the Mexican House of Representatives.

Dr. R. Cepeda, president of the Board of Aldermen, has asked to be relieved of his place, because of his being a senator. He probably will be succeeded in his aldermanic position by another physician, Dr. L. Coyula.

Dr. M. Aveleyra and Dr. A. B. Vasconcelos have obtained permission from the university authorities to give extra courses (cátedras libres) in the School of Medicine on medical pathology.

LONDON LETTER

LONDON, April 7, 1919.

Chemistry in the National Service

At the annual meeting of the Chemical Society, the president, Sir W. J. Pope, delivered an address which showed how British science in the end outclassed the long and careful preparations of the Germans. He remarked that the efficiency of the British gas protection, which called for the exhibition of so much scientific skill both in research and in manufacture, was an illustration of the paramount importance of science which appealed to the general public; but it was only a small branch of the enormous chemical problem which presented itself to the nation nearly five years ago and which led to the formation of the department of explosives supplies. As the magnitude of the struggle became gradually obvious, it was realized that the whole of the resources of the empire would have to be utilized. A census of all available chemical products had to be taken, and schemes for their exploitation laid down; all materials had to be apportioned with the knowledge that whatever was used for the manufacture of one particular war product left a corresponding shortage of that particular raw material in connection with the manufacture of some other and perhaps equally essential product. The necessity for utilizing all the chemical resources of the country led to the attempt to extract the last possible fraction of efficiency in each component process, and the huge production—at the time of the armistice the country was making about 100,000 tons yearly of nitric acid and sulphur trioxid, 60,000 tons of trinitrotoluene and 35,000 tons of cordite—made it profitable to carry out a vast amount of careful scientific investigation of details of manufacture.

An instructive example of the results of the struggle for economy was found in the rivalry which arose between picric acid and ammonium nitrate as high explosives. The former cost about $925 a ton to make, the latter about $250, and trinitrotoluene about $500. A mixture of trinitrotoluene and ammonium nitrate, known as amatol, which was introduced early by the research department at Woolwich, was less costly to manufacture, apart from other advantages. The growing appreciation of its merits led to discontinuance of the manufacture of picric acid in this country last summer, to its adoption in place of picric acid as the American standard high explosive, to the approaching elimination of picric acid from the Italian military program, and to replacement of picric acid by amatol in the French service. Our production of the chemical materials needed for a great European war, though negligibly small in 1914, gradually attained satisfactory dimensions. The great chemical factories of Central Europe could divert their production at very short notice. Why, then, were the Allied nations given time to develop their war production of explosives and noxious materials from nothing? When in July, 1917, the Germans first began to use the so-called mustard gas, British chemists were amazed to find, from examination of the product, that it was being manufactured by a technically cumbrous process that gave a yield of, perhaps, 40 to 60 per cent. of the theoretical. By the end of January, 1918, we had worked out a process which yielded in the laboratory from 98 to 99 per cent. of the theoretical. This was communicated to our allies, who at the time of the armistice had an available daily production of mustard gas equal to the monthly production of the Central nations. German chemical service was, therefore, inefficient and the scientific chemists under its control were incompetent. But while other instances could be given to show that Germany was badly served by her scientific men during the war, it would be difficult to overrate the skill and perseverance exhibited by the German chemical manufacturers. The view that this country is superior to Germany in the possession of creative scientific power had always been maintained in modern times by students of philosophy and history, and was amply demonstrated during the last four years. While we overcame our handicap by a continuous flow of novel scientific devices of military value, our enemies passed through the war with little more in the shape of novel effects than those laboriously elaborated during the preceding years of peace.

"Colonies" in the Treatment of the Tuberculous

A memorandum on the share of "Colonies" (institutions for training and for employment) in the treatment of the tuberculous, prepared by Dr. J. E. Chapman, medical inspector of the local government board, has been issued. In a prefatory note, Sir Arthur Newsholme, late medical officer of the board, says that the memorandum indicates possible lines of development, and points out that for control over tuberculosis to be satisfactory it must extend beyond sanatoriums and colonies and include satisfactory housing. It is uneconomical to neglect the home life of consumptives on whose previous medical treatment large sums have been spent, either as regards bedroom accommodation or the nutrition of the patient or his family. No scheme for the control of tuberculosis can be regarded as satisfactory which does not embrace the whole life of the consumptive patient.

Dr. Chapman states in his memorandum that colony treatment is the natural development of measures taken in sanatoriums to secure for selected patients more permanently beneficial results than can be obtained by sanatorium treatment alone. The work provided in the earlier colonies was usually agricultural, but few of the patients continuing in their occupations after discharge from the colony. More recently colonies have been established in which patients are employed and trained in occupations which, although prima facie not so suitable as agriculture, can be followed under reasonably good conditions, and are likely to be adopted by the patients as a means of earning their livelihood.

The first point to decide is whether or not a patient can return to his old occupation. If this is consistent with his health and offers an adequate wage, the idea of a new occupation should not be entertained. The occupation selected should give an almost assured outlook for continuous employment with adequate wages and under reasonably good working conditions. Although better results may be anticipated for colony treatment than is practicable under present conditions of sanatorium treatment, there remains considerable risk of the breakdown of the patient on his return to ordinary life. To minimize this risk the services of care committees should be available to assist patients after discharge from the colony. It is important also that ex-patients should be housed under conditions which will enable them to maintain health. It is suggested that about 5 per cent. of the new houses to be built under impending housing schemes should have a separate bedroom for the patient, in which free perflation of air is secured. The extension of colony treatment to certain classes of patients in which the disease is unlikely to become arrested is worthy of consideration. The colony might be used with advantage as a half-way house between the sanatorium and ordinary life for patients whose health has been greatly improved by sanatorium treatment, but who will probably relapse very quickly if the transition to full work is abrupt. Provision might also usefully be made at colonies situated near a town for the part-time employment of irrecoverable patients whose working capacity is temporarily or permanently impaired. The provision of suitable part-time work adapted to their capacity and of suitable housing would enable the patients and their families to derive the maximum benefit from such financial assistance as is available. This further development of colonies would not only benefit the patients, but would also form an important measure for diminishing the spread of infection.

PARIS LETTER

PARIS, April 10, 1919.

Treatment of War Injuries of the Spinal Cord

At a recent meeting of the Société de chirurgie de Paris, Dr. Tuffier read a communication on this subject from Dr. R. Dumas. Dumas is of the opinion that wounds of the spinal cord should be subjected to the same treatment as all other war wounds, that is to say, by excision, removal of fragments of bone, repair of nerve lesions—when that is possible—and closure of the wound. Tuffier, however, does not believe that such treatment should be the rule, because in a large number of cases when the patient is in shock his life would be endangered by operation, whereas after ten or twelve days the operation is no more serious than with any ordinary war wound. Dumas' statistics confirm this statement: In thirteen cases in which operation was done between the first and the fifth day after the injury occurred, death resulted in five; while only three fatalities occurred in twelve cases in which operation was done some time during the first two months after the wound was inflicted. None of the patients who were operated on early received any special benefit therefrom, nor was there any return of motion or any improvement in sphincter function, and only three showed evidence of slight regression of anesthesia and corresponding return of sensation. Nor did those patients who were operated on late show any evidence of improvement. Nothing, in short, seems to justify the opinion that wounds of the spinal cord should be treated like other war wounds, and early intervention does not seem to be called for. An exception should be made, however, in those cases which present incomplete lesions or compression of the cord by a projectile or a bone fragment, as shown clearly in the roentgenogram. In these cases marked improvement may be obtained by immediate operation, but it must be borne in mind that removing the cause does not necessarily suppress the effect. Even after removing the intramedullary projectile or the bone fragment, or after relieving compression caused by a displaced vertebra, functional disturbances may persist, sometimes indefinitely. Everything depends on how much pathologic change has taken place in the cord. However, it is certain that in all cases in which incomplete division or compression of the cord is suspected, intervention, after the shock symptoms have disappeared, is indicated.

The Smallpox Vaccination Service During the War

Dr. A. Fasquelles, director of the Service antivariolique e l'Armée, recently read a report at the Académie de médecine on the work done by his department and the results that had been obtained during the war. This Centre vaccinogène de l'Armée was organized by the Service de Santé militaire, and it succeeded in ministering to the needs of the various armies, the navy and the colonies in the tropics. The average of positive revaccinations exceeded 50 per cent. During the war of 1870-1871 more than 120,000 French soldiers were infected with smallpox, and more than 25,000 died; during the recent war only twelve cases occurred in the metropolitan French army, with only one death. This is the first time that a war has not been accompanied by a smallpox epidemic.

Progress of French Medicine

In response to a request made by the medical department of the U. S. Army, biweekly medical meetings are to be held in the Grand Amphithéâtre of the Paris medical faculty for the purpose of discussing contributions made to medicine by French investigators. At the first two meetings Professor Richet will describe the work of Descartes, Lavoisier, Bichat, Claude Bernard and Pasteur.

French Urologic Society

The Société française d'urologie has been formed in Paris. Its membership will consist of active and honorary members. Professor Guyon is honorary president and Dr. Legueu, professor of diseases of the genito-urinary system on the Paris medical faculty, is president.

To Increase the Birth Rate

M. Simonet submitted a report to the senate on the proposition advanced by him to increase the donations to be made to public and private enterprises engaged more particularly in raising the birth rate and promoting infant welfare.

Association of the War Blinded

The war blinded have formed an association to provide means for putting to the best use the activities of which they are still capable and for mutual aid and moral and material welfare. Plans will be studied to establish funds for mutual aid, to cooperate in the purchase of raw materials, arrange for cooperative work and salesrooms, in short, to provide for every possible means and measures which will make the life of the blind easier.

Closing the Spanish Hospital

The Spanish hospital has recently been closed with suitable ceremonies. This hospital was established for the French wounded at the instance of King Alphonso; the maintenance and management were in charge of the Spanish colony. M. de Quinonès de Leon, the Spanish ambassador, presided. The grand cross of the Mérite militaire was awarded to Dr. de Sard, the physician in chief of the hospital, and other crosses of the same order were given to all those who had volunteered their services to realize this important war work.

Antialcohol Conference

At the suggestion of the English and American representatives of the antialcohol movement, the Ligue nationale contre l'alcoolisme has summoned a Conférence internationale des hygiénistes of all countries of the world, both allied and neutral. This conference holds its sessions in the headquarters of the Ligue, April 3 to 5, 1919. The following propositions will be discussed: (1) List of antialcohol desiderata to be submitted to the Peace conference in conformity with Article 19 of the constitution of the League of Nations; (2) special measures taken against alcohol during the war; (3) the new aspect to be given, after peace is declared, to the organization of the international defense against alcohol; (4) measures to be taken to develop further the scientific and statistic researches already in progress, notably those under way at the Bureau international de Lausanne.

Fraternizing of American and French Students

The Association générale des étudiants de l'Université de Paris recently tendered a reception to the American students returning from the front. M. André Tardieu, general commissioner of affaires de guerre franco-américaines, presided and was assisted by M. Lucien Poincaré, rector of the University of Paris, the deans of the faculties and numerous professors and Colonel Exton, in charge of the American student soldiers. M. Tardieu in the course of impromptu remarks dwelt on the community of ideals which had brought about the Franco-American alliance, and voiced his approval of the students' plea—that their comrades be permitted to return to their studies as soon as possible. He promised to use his influence with parliament and the government to bring this about.

Scientific Institute Established at Saigon

M. Albert Sarraut, governor-general of Indo-China, recently announced the establishment of a scientific institute at Saigon, to study the development and utilization of the products of the soil and of the water of Indo-China. An inventory will be made of the natural resources of Indo-China, and the institute will aim to exploit them properly by means of laboratory studies, experimental research and scientific explorations.

Removal of Certain Food Control Measures

M. V. Boret, minister of agriculture and food commissioner, has removed certain restrictions on foods, such as the restriction on the manufacture and sale of fresh pastry, the use of bread flours for making biscuits and pastry; the manufacture and sale of desiccated, sterilized or condensed milk, of butter, cheese and other milk products; the manufacture and sale of confectionery, especially of chocolate confections and milk chocolate, likewise the restriction on the use of eggs and butter for making crackers (biscuiterie) and pastry.

Personal

Dr. Albert Calmette, former director of the Institut Pasteur at Lille, now subdirector of the Institut Pasteur at Paris, was recently elected an active member of the section on public hygiene and legal medicine of the Académie de médecine.

Marriages

C. Harold Heffron, Lieut., M. C., U. S. Army, Metamora, Ohio, on duty at Fort Sheridan, Ill., to Miss Elsie Lindbergh of DeKalb, Ill., at Chicago, April 8.

John Francis Fennessey, Capt., M. C., U. S. Army, Dorchester, Boston, to Miss Katherine T. Whalen of Brookline, Mass., April 22.

Malcolm McLean Morrison, Lieut., R. A. M. C., Los Angeles, to Miss Antoinette Miklau of San Francisco, at Los Angeles, April 4.

John Henry Ernest Fust, Lieut., M. C., U. S. Army, Carney's Point, N. J., to Miss Dorothy M. Cooke of Yonkers, N. Y., April 26.

Garrette Van Sweringen, Fort Wayne, Ind.; to Miss Mary E. MacDonald of Columbia City, Ind., at Fort Wayne, April 21.

John Edward Kelley, Capt., M. C., U. S. Army, to Miss Rose Ann Gahan, both of Chicago, April 26.

Ada Scott Conner Morton, San Francisco, to Robert Frederick Lewis, in New York, May 1.

Albert S. Lowenson to Miss F. Carlyn Hanline, both of Baltimore, April 30.

Emmet Francis Casey to Miss Elsa E. Singer, both of Chicago, January 8.

Deaths

Grenville Mellen Weeks, Kearny, N. J.; New York University, New York City, 1861; aged 81; surgeon, U. S. Navy, and later major and surgeon and brigade surgeon of U. S. Volunteers and medical director of the district of Florida during the Civil War; who reentered the service in 1865 as surgeon and acting Indian agent during the Indian troubles in Minnesota and the Dakotas; author of the resolution recognizing Cuban independence, which was adopted by Congress in 1898; organizer and president in 1869 of the first Christian union, to urge a universal peace union of all creeds; died at the Soldiers' Home, Kearney, N. J., April 25.

Walter Stevenson Slicer ⊕ Lieut., M. C., U. S. Army, Roanoke, Va.; University College of Medicine, Richmond, Va., 1904; aged 38; who closed his hospital, known as Slicer's Hospital, Roanoke, July 1, 1918, to enter the Army and was in training in Fort Oglethorpe, Ga., and later was stationed at Base Hospital No. 124, Camp Hancock, Ga., and was honorably discharged from the Army, January 17; who was operated on for the removal of tonsils and adenoids, January 22; died twelve hours later from cerebral embolism.

William E. Lawrence ⊕ North Haverhill, N. H.; Baltimore Medical College, 1896; aged 47; medical referee for Grafton County; a specialist in tuberculosis; a member of the state constitutional convention in 1912, and a member on the state legislature in 1913 and 1914; formerly a trustee of New Hampshire state institutions; a trustee of Haverhill Academy and Woodsville Guaranty Savings Bank; died in the Woodsville Hospital, April 19.

Floyd S. Crego, Buffalo; Medical College of Ohio, Cincinnati, 1879; a member of the Medical Society of the State of New York; neurologist to Erie County, Emergency, Mercy and German hospitals, Buffalo; formerly professor of nervous and mental disease in the medical department of Niagara University; a member of the Buffalo Academy of Medicine, and a well known alienist; died at his home, April 23, from angina pectoris.

Pearl Tenney Haskell, Bangor, Me.; Bowdoin Medical School, Brunswick and Portland, Me., 1893; aged 50; a member of the Maine Medical Association; for two years assistant superintendent of the New Hampshire State Hospital, Concord, and from 1914 to 1917 assistant superintendent of the Maine State Hospital at Bangor, and since July, 1917, superintendent of the institution; died at his home, April 13.

Duncan R. MacMartin ⊕ Chicago; McGill University, Montreal, 1888; aged 57; a well known surgeon; associate professor of surgery in the Chicago Polyclinic; a member of the staff of the Polyclinic, St. Luke's and Henrotin hospitals; medical director of the American Bankers' Insurance Company; was found dead in his room in the Great Northern Hotel, April 30, from cerebral hemorrhage.

Herbert Martin Bishop, Los Angeles; Yale University, New Haven, Conn., 1865; aged 75; surgeon of the First Connecticut Volunteer Cavalry during the Civil War; once president of the California State Homeopathic Society; widely known as an amateur astronomer; died at his home, April 23.

Emmet V. Ball, Atlanta, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1894; aged 48; a specialist on diseases of the eye, ear, nose and throat; professor of laryngology and rhinology in his alma mater; died at his home, April 23, from heart disease.

Calvin Sloane May ⊕ New York City; Yale University, New Haven, Conn., 1873; aged 71; a member of the New York Academy of Medicine; at one time acting superintendent of the Connecticut Hospital for the Insane; died suddenly at his home, April 26.

Dwight Silliman, Hibbing, Minn.; New York University, New York City, 1866; aged 77; for many years a practitioner of Hudson, Wis., but since 1914 a resident of Hibbing; died at the home of his son in Hibbing, April 19, from cirrhosis of the liver.

Lucinda L. Combs Strittmatter, Columbus, Ohio; Woman's Medical College of Pennsylvania, Philadelphia, 1873; aged 70; a pioneer medical missionary in China, where she served from 1873 to 1881; died at the home of her son in Columbus, April 23.

Francis Joseph Giblin, Boston; Harvard Medical School, 1893; aged 51; a member of the Massachusetts Medical Society; formerly chairman of the medical staff of St. Mary's Infant Asylum, Dorchester, Boston; died at his home, April 13.

John William Hurley, Elizabeth, N. J.; New York University, New York City, 1882; aged 60; for three years an apothecary in the Navy; died at his home, April 15, from endocarditis following chronic articular rheumatism.

James Madison Lovelady ⊕ Sidney, Iowa; College of Physicians and Surgeons of St. Joseph, Mo., 1881; Missouri Medical College, St. Louis, 1887; aged 64; died at his home, April 3, from cerebral hemorrhage.

William Charles Langman, Cleveland; Eclectic Medical Institute, Cincinnati, 1898; aged 56; died in the Cleveland City Hospital, April 11, from injuries received March 3, when he was struck by an automobile.

C. Henry L. Bush, Woodville, Ohio (license, Ohio, 1896); aged 79; one of the incorporators of Woodville, and for several years a member of the board of education; died at his home, April 17, from uremia.

Benjamin G. Allen, Chattanooga, Tenn. (license, Tennessee, 1890); a practitioner since 1888; aged 49; a member of the Tennessee State Medical Association; died at his home, April 11.

Clyde Roy Rorabaugh, Seattle; Medico-Chirurgical College of Philadelphia, 1903; aged 39; a member of the Washington State Medical Association; died at his home, April 16.

Nathan Newby, Wichita, Kan.; Physio-Medical College of Indiana, Indianapolis, 1876; aged 77; a practitioner since 1869; died at his home, April 22, from cerebral hemorrhage.

Francis O. Lowe, Kewanee, Ill.; University of Illinois, Chicago, 1886; aged 57; a member of the Illinois State Medical Society; died at his home, April 27, from pneumonia.

Joseph Mark Kearney, Chicago; Rush Medical College, 1897; aged 44; formerly assistant physician at the Elgin State Hospital; died at his home, April 15, from pneumonia.

Chalmer Nathan Hatfield, Fostoria, Ohio; University of Illinois, Chicago, 1904; aged 42; a member of the Ohio State Medical Association; died at his home, April 22.

Alexander B. McCrea, Berwick, Pa.; Long Island College Hospital, Brooklyn, 1865; aged 81; a veteran of the Civil War; died at his home, April 12, from influenza.

Elias Hicks Trueblood, Salem, Ind.; Physio-Medical College, Cincinnati, 1885; aged 88; died at the home of his daughter in Salem, March 4, from senile debility.

Alfred J. Becker, Catasauqua, Pa.; Hahnemann Medical College, Philadelphia, 1885; aged 58; died at his home, April 16, after an operation for epiplopexy.

Marshal William Craton, Carrollton, Mo.; New York University, New York City, 1882; aged 62; died at his home, April 5, from cerebral hemorrhage.

Theodore B. Redmond, Danville, Ill.; Indiana Medical College, Indianapolis, 1875; aged 72; died at his home, April 18, from cerebral hemorrhage.

James Wardrope Ellis, San Jose, Calif.; New York University, New York City, 1882; aged 69; died at his home, March 3, from cerebral hemorrhage.

William Alexander Melton, Jr. ⊕ Warrensburg, Ill.; Northwestern University Medical School, Chicago, 1896; aged 56; died at his home, March 28.

Irénée Cier, Monroe, La.; Tulane University, New Orleans, 1898; aged 41; also a druggist; died at his home, April 17, from cerebral hemorrhage.

James W. Harris, New York City; United States Medical College, New York City, 1882; aged 71; died at his home, April 13, from pneumonia.

John W. Rutledge ⊕ Minneapolis; Medical College of Ohio, Cincinnati, 1875; aged 74; died at his home, February 24, from arteriosclerosis.

Joseph James Hartley, Richmond, Va.; Meharry Medical College, Nashville, Tenn., 1908; aged 42; was found dead in his home, March 21.

Edward Everett Dowdle ⊕ Silver City, N. M.; Hahnemann Medical College, Philadelphia, 1912; aged 31; died at his home, January 11.

Robert J. Arnold, Hampton, Ga.; Eclectic Medical Institute, Cincinnati, 1883; aged 56; died at his home, March 14, from pneumonia.

John H. Wilder ⊕ Hooks, Texas; Chattanooga (Tenn.) Medical College, 1893; aged 51; died in El Paso, Texas, April 20.

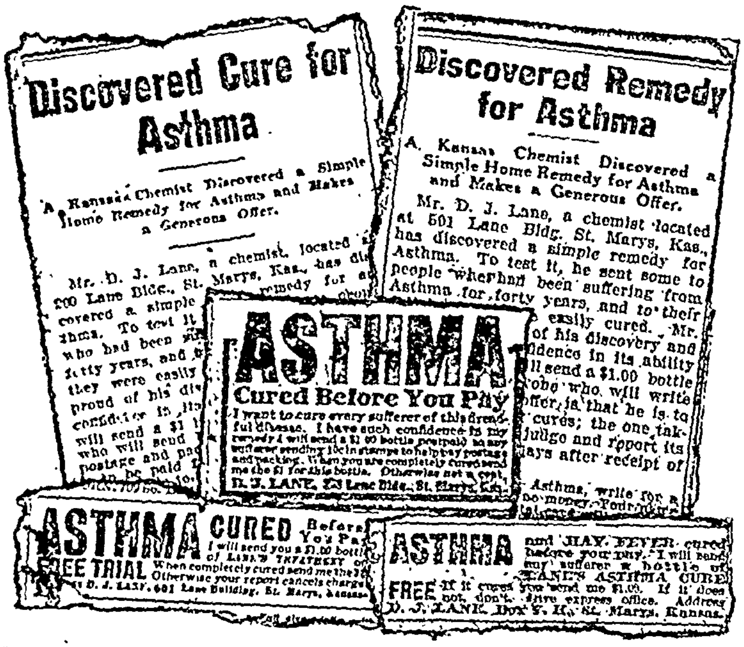
The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

LANE'S ASTHMA CURE

In certain cheap weeklies and in some not-too-particular newspapers, one may find advertisements in large black-faced type announcing: "Asthma Cured Before You Pay," in which D. J. Lane, St. Marys, Kan., offers to "send you a $1.25 bottle of Lane's Treatment on free trial." Other advertisements headed either "Discovered *Cure* for Asthma," or "Discovered *Remedy* for Asthma," as the advertising rules of the publication may require, assert that a "Kansas Chemist" has discovered a "simple home remedy for asthma" which has "easily cured" those "who had been suffering from asthma for forty years."

In earlier days, "Lane's Asthma Treatment" used to be "Lane's Asthma Cure," and long after the federal Food and Drugs Act was enacted, which penalizes false claims made on the trade package, the same false claims were made in other advertising paraphernalia—not subject to the law—which Lane used in his mail-order quackery.



Discovered Cure for Asthma

A Kansas Chemist Discovered a Simple Home Remedy for Asthma and Makes a Generous Offer.

Mr. D. J. Lane, a chemist, located at 200 Lane Bldg., St. Marys, Kas., has dis-covered a simple remedy for as-thma. To test it who had been su forty years, and they were easily proud of his dis confidence in its will send a $1 who will send postage and pa be paid

Discovered Remedy for Asthma

A Kansas Chemist Discovered a Simple Home Remedy for Asthma and Makes a Generous Offer.

Mr. D. J. Lane, a chemist located at 501 Lane Bldg. St. Marys, Kas., has discovered a simple remedy for Asthma. To test it, he sent some to people who had been suffering from Asthma for forty years, and to their easily cured. Mr. of his discovery and dence in its ability ll send a $1.00 bottle who will write offer is that he is to cures; the one tak- judge and report its days after receipt of Asthma, write for a no money.

ASTHMA
Cured Before You Pay

I want to cure every sufferer of this dreadful disease. I have such confidence in my remedy I will send a $1.00 bottle postpaid to any sufferer sending 10c in stamps to help pay postage and packing. When you are completely cured send me the $1 for this bottle. Otherwise not a cent.
D. J. LANE, 233 Lane Bldg., St. Marys, Kan.

ASTHMA CURED Before You Pay
FREE TRIAL
I will send you a $1.00 bottle of LANE'S TREATMENT on When completely cured send me the $1 Otherwise your report cancels charge
D. J. LANE, 601 Lane Building, St. Marys, Kansas

ASTHMA and HAY FEVER cured before you pay. I will send any sufferer a bottle of LANE'S ASTHMA CURE
FREE If it cures you send me $1.00. If it does not, don't. Give express office. Address D. J. LANE, Box Y, K., St. Marys, Kansas.

Reproductions (reduced) of advertisements of Lane's Asthma Cure of various dates.

"Lane's Treatment" was purchased and submitted to the A. M. A. Chemical Laboratory. The chemists' report follows:

CHEMISTS' REPORT

"Lane's Treatment, Double Strength, for Asthma and Hay Fever," a specimen of which was recently examined in the A. M. A. Chemical Laboratory, was a brown liquid containing suspended matter, and having an aromatic odor and a bitter, gentian-like taste. The specific gravity of the liquid was 1.0471. "Twelve and a half per cent. of alcohol, or less," was declared on the label. Qualitative tests indicated the presence of alcohol, calcium, iodid, sugar and vegetable extractives. Most of the sugar present was in a form which directly reduced Fehling's Solution (such as glucose), although a small amount had the characteristics of sucrose (cane or beet sugar). In an older specimen, which had been in the A. M. A. files for some time, the sugar was wholly sucrose. No alkaloidal or emodin-bearing (laxative) drugs were present. Quantitative determinations gave the following results:

	Per Cent.
Alcohol, by volume	11.30
Calcium (Ca^{++}), by weight	0.59
Iodin (present as Iodid-I^-), by weight	3.26
Ash, by weight	2.05
Sugar (Direct Reduction calculated as dextrose), by weight	5.93
Total Sugar (After Inversion calculated as dextrose), by weight	6.36

The examination indicated that each 100 c.c. (approximately 3⅓ fluidounces) contained 11.3 c.c. (about four teaspoonfuls) of alcohol, 3.96 grams (60.8 grains) of anhydrous calcium iodid (CaI_2) and 6.66 grams (about 102 grains) of sugar, chiefly dextrose.

It will be seen by the chemists' report that Lane's "wonderful discovery for asthma" is essentially a solution of iodids in alcohol and water with vegetable extractives. Each dose of Lane's preparation contains approximately 2.5 grains of calcium iodid. This gives a daily dosage which is equivalent to 11.3 grains of potassium iodid. Iodids, of course, have been used for years by the medical profession in the treatment of certain forms of asthma. Under careful supervision the use of iodids in selected cases of asthma may give satisfactory results. Self-dosing with iodids, however, especially in cases in which the conditions may or may not indicate this drug, is by no means free from danger. Long continued use or overdosing may bring about symptoms of iodism with edematous conditions of the larynx that may seriously interfere with respiration, even to the point, occasionally, of necessitating tracheotomy and in rare instances, causing death. Even where the symptoms are not so severe there may be skin eruptions, frontal headache, sore throat, neuralgic pains, anemia, etc. It is hardly necessary to say that in the exploitation of Lane's nostrum there is no warning of such danger.

Correspondence

THE ADMINISTRATION OF ARSPHENAMIN

To the Editor:—It appears that there is a lamentable want of care on the part of many physicians who administer arsphenamin as to the concentration of the drug used and the time required for administration.

The Hygienic Laboratory receives many complaints in regard to untoward results from the administration of arsphenamin made by various American producers. When careful investigation is made it is almost invariably found that the drug has been used in a solution that is too concentrated, and that it has been administered too rapidly. We have reports of a dose of 0.4 gm. being given in a volume of as little as 25 c.c. and injected within thirty seconds. Such practice is abuse, not use, of a powerful therapeutic agent.

If, in addition to the usual precautions as to the use of perfect ampules and neutralization, physicians would give the drug in concentration of not more than 0.1 gm. to 30 c.c. of fluid and allow a minimum of two minutes for the intravenous injection of each 0.1 gm. of the drug (in 30 c.c. of solution) the number of reactions would be very materially reduced. This would necessitate from 30 to 180 c.c. of the solution for the doses usually given and would require from six to twelve minutes for the injection.

Any physician who fails to observe these precautions should be considered as directly responsible for serious results that follow the improper use of the drug.

G. W. McCoy, M.D., Washington, D. C.
Director, Hygienic Laboratory, U S. P. H. S.

[Note.—The United States Public Health Service has issued a circular to its officers concerning the proper mode of administering these preparations. It is appropriate to reproduce this circular in connection with the letter of Dr. McCoy. Careful attention to the letter and the following points from the circular mentioned will undoubtedly reduce the number of reactions following the use of arsphenamin preparations.]

OPENING OF THE AMPULE

The ampule, before opening, should be immersed in 95 per cent. alcohol for fifteen minutes, so as to detect any crack or aperture not primarily recognizable. (Should such a breach be discovered, the contents of the ampule should be discarded.)

ARSPHENAMIN

(1) Solution: Cold, boiled, freshly distilled water should be used in all cases except in the case of "arsenobenzol" made by the Dermatological Research Laboratory, in which case hot water is required. No more solution should be prepared at one time than can be given in thirty minutes.

(2) *Neutralization and Alkalinization of the Above Solution:* With a graduated pipette or burette add 0.9 c.c. of normal NaOH for each 0.1 gm. of the drug (i. e., 5.4 c.c. for each 0.6 gm.). The alkali should be added all at once and should quickly convert the acid salt solution of arsphenamin into the alkaline salt solution, or the disodium of salt of the arsphenamin base The solution of arsenobenzol, which is hot, should be cooled before adding the alkali. This represents slightly more alkali than just enough to redissolve the precipitate formed by the addition of this reagent.

The alkali used should be standardized against normal acid. Normal NaOH is a 4 per cent. solution of the c.p. product. However, if made on the basis of weight, it may be considerably less than this strength, hence the necessity for titration. It could be made up in amount sufficient for a month's use, if kept in a well-stoppered bottle and exposed to the air for only a few seconds at a time when using the solution. It should be kept in a bottle that has been used for NaOH solution for some time so that all action it might cause on the glass has already occurred. Where it is impossible to have this made up at the station, it will be furnished on request from the Hygienic Laboratory. Should the NaOH solution become cloudy or contain a precipitate, it should be discarded.

(3) *Concentration of the Drug:* It is desired to emphasize the fact that the concentration of the drug should not be greater than 0.1 gm. to 30 c.c. of final solution. The practice of using concentrated solution is not only in direct conflict with the instructions on the circular, but carries a distinct hazard to the patient.

(4) *Method of Infection:* The gravity method only should be used. Where several patients are to be injected from the same solution, the container for the solution should be graduated. If not already graduated, this can be done in a few minutes by sticking on a strip of adhesive plaster and marking the graduations on this. A convenient way to do this is to have each mark represent 30 c.c. with a long mark for each 180 c.c.; then, if the volume is made up so that each 0.1 gm. of drug is contained in each 30 c.c., the doses can be given accurately. It is a great convenience to have a glass stopcock near the glass tubing which serves as a window just above the needle in order to control the rate of injection. If no stopcocks are at hand, the rate can be controlled by the size of the needle and the height of the column of fluid. A No. 18 or 20 B&S gage is the best size needle.

(5) *Rate of Injection:* Operators should pay particular attention to the rate of administration and in no case exceed 0.1 gm. of drug (30 c.c. of solution) in two minutes. This point is especially emphasized because it is believed that excessive rapidity of administration accounts for more unfavorable results in the use of arsphenamin than any other one thing.

NEO-ARSPHENAMIN

The principal precautions to be observed in the administration of neo-arsphenamin are:

(1) But a single ampule should be dissolved at a time. This drug must not be dissolved in bulk to be given to a series of patients.

(2) Cold water only should be used.

(3) The dilution should be not stronger than 0.1 gm. of the drug in 2 c.c. of freshly distilled water.

(4) A very small needle should be used, and the time of injection of the dose should be not less than five minutes.

SMITH COLLEGE TRAINING SCHOOL FOR SOCIAL WORK

To the Editor:—May I call the attention of your readers to a new opportunity for the intensive training of medical-social workers—the new Smith College Training School for Social Work?

Every hospital of importance in the country now employs or knows it ought to employ social workers to attend to that fringe of nonmedical needs that surrounds certainly 40 per cent. of the patients in free hospitals. Medical problems are so closely enmeshed with mental, moral, financial, industrial, racial and domestic problems, that we really cannot cure most of our hospital patients (and especially outpatients) without the help of the right sort of woman who will help us to understand and to mitigate the mass of ignorance, fear, bad habit, resourcelessness and poverty which still weigh them down even after they have been scientifically diagnosed and treated.

Such a woman must first be born to the job and then trained for it. The training referred to above begins this summer, and as chairman of the Advisory Committee on this work at Smith College, I want to make known its opportunities as widely as I can. I will answer or get answered any inquiries regarding it.

RICHARD C. CABOT, M.D., Boston.

IDENTITY OF THE POPPY IN FLANDERS FIELDS

To the Editor:—The inquiry concerning the nature of the poppies in "Flanders Fields" leads me to call attention to the fact that these flowers have been a feature of the region for centuries, for Macaulay, in his History of England, in speaking of the battle-field of Landen (during the reign of William III of England), says: "The next summer the soil, fertilized by twenty thousand corpses, broke forth into millions of poppies. The traveler who, on the road from St. Tron to Tirlemont, saw that rich sheet of scarlet spreading from Landen to Neerwinden could hardly help fancying that the figurative prediction of the Hebrew prophet was literally accomplished; that the earth was disclosing her blood and refusing to cover the slain."

HENRY LEFFMANN, M.D., Philadelphia.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

PEPSODENT

To the Editor:—Please give me an opinion concerning the dentifrice "Pepsodent." It seems very gritty to me, and I wonder whether the abrasive used will not be injurious to the teeth. The manufacturer claims it to be precipitated calcium phosphate. The pepsin contained is said to be "activated" by some agent other than an acid. A recommendation by the Carr School of Preventive Dentistry and Medicine at 30 N. Dearborn St., Chicago, is published. Is it a school whose recommendation is authoritative?

EARL H. CORNELL, Oakland, California.

ANSWER.—The keynote of the "Pepsodent" advertising is the claim that, used as a dentifrice, it will digest or dissolve the dental mucin plaques through the action of pepsin which has been incorporated in the paste. The acid medium necessary for the activation of the pepsin is claimed to be acid calcium phosphate; the abrasive substance said to be used is tricalcium phosphate. Pepsodent has been exhaustively studied by Dr. William J. Gies and his collaborators in the Biochemical Laboratory of the Schools of Medicine and Dentistry of Columbia University. Dr. Gies in a letter published in THE JOURNAL, April 28, 1917, briefly summarizes the findings of this investigation. Regarding the alleged digestive powers of Pepsodent, Dr. Gies wrote:

> "We have found that none of these digestive claims is warranted in any degree. 'Pepsodent' is devoid of the digestive power on dental mucin plaques that is commercially ascribed to it. Mucin plaques cannot be digested from teeth by any advertised use of 'Pepsodent.' There is about as much common sense in the proposed application of 'Pepsodent' for this purpose as there is in the oral administration of a few grains of lactopeptin to improve impaired tryptic digestion in the intestine."

A complete report of the investigation of Dr. Gies and his collaborators appeared in *The Journal of the Allied Dental Societies*, September, 1917. The investigation showed that the acidity of Pepsodent is due largely, if not entirely, to acid calcium phosphate. The claim by the Pepsodent concern that the use of this preparation stimulates the production of saliva is true. It does stimulate the flow of saliva to an extent that speedily neutralizes the very feeble acid present in Pepsodent. Thus, any possible influence that this "acid" might otherwise exert is, as Dr. Gies says, "promptly and completely nullified." As to whether the abrasive used in Pepsodent is injurious to the teeth, Dr. Gies reported that it appeared "to be devoid of harmful mechanical influence on dental enamel" in the ordinary use of the preparation as a dentifrice. He added: "We are not positive on this point, however."

The "Carr School of Preventive Dentistry" seems to be operated by one C. M. Carr, who has invented a set of dental instruments, and has devised what seems to be called the "Carr Treatment." The treatment and the instruments it appears are for use in cases of pyorrhea alveolaris. According to the catalog, the "Course of Prevention, including the cure of Pyorrhea" is completed in four weeks and costs $175. A call at 30 North Dearborn Street disclosed empty rooms where the "Carr School of Preventive Dentistry" had been. Inquiry as to where the "school" now is evoked the enigmatical reply that it was "going out West for a few months."

MORTALITY FROM TUBERCULOSIS IN JAPAN—LACTATION IN JAPANESE WOMEN — DAIRYING IN JAPAN

To the Editor:—1. Is it true that the mortality from tuberculosis in Japan is very low—much lower than in the United States? 2. Do the Japanese children nurse until they are five or six years old? 3. Is Japan a cowless nation?

M. E. J., Calif.

ANSWER.—1. According to the 1911 report of the Imperial Japanese Institute for Infectious Diseases the number of soldiers and sailors discharged each year on account of tuberculosis has markedly increased in recent years. According to the reports of various life insurance companies, out of 100 deaths from 20 to 25 per cent. were due to tuberculosis. Reports from textile factories show a relative mortality of from 25 to 43 per cent., silk factories having the heaviest mortality. According to the statistics of the three years 1906-1908, 30 per cent. of all deaths among factory workers were due to pulmonary tuberculosis, 12 per cent. to diseases of a seemingly tuberculous nature, and 6.4 per cent. to tuberculosis of other organs than the lungs. Accordingly nearly 50 per cent. of all deaths were in some way connected with tuberculosis. It is stated in the report of the Imperial Japanese Institute that the mortality from tuberculosis in Japan seems to agree closely with the results of the investigations made by Baumgarten and Orth in Germany. The incidence of tuberculosis in Japan does not therefore seem to differ materially from that in the United States.

2. Japanese women are noted for their ample supply of milk, although this is said to be on the decrease in recent years. They often nurse their children three years and over—even seven years occasionally. The reason commonly assigned is peculiar, namely that the Japanese mother thinks that by nursing her child for so long a period she gains better control over the child, not only during the actual period of lactation but during the following years, as well.

3. Japan is fairly well supplied with dairy cattle. It is, however, doubtful if the quality of the herds ranks as high as in Switzerland, Denmark and some portions of our own country. The reasons for the long nursing of children are not to be sought in the scarcity of cows but rather in the peculiar ideas that the Japanese entertain of the family.

CESSPOOLS, INFECTED VEGETABLES AND TYPHOID

To the Editor:—1. Will you kindly give me some information concerning cesspools? Have typhoid epidemics been traced to this source? 2. Is it true that cases of typhoid have been traced to vegetables that have been fertilized with night soil?

A. E.

ANSWER.—1. There is no doubt that a proper mode of disposal of human excrement by water carriage leads to a reduction in the amount of typhoid fever. Chapin states that in Providence, R. I., the disease fell off 40 per cent. after most of the privy vaults were abolished. Many other American cities and also many English cities have had similar experience. A number of references are given by Chapin in "Sources and Modes of Infection" (John Wiley & Sons, New York, 1912), p. 180. 2. With regard to the possibility of typhoid infection through vegetables, a discussion of this subject with references and a report of original work has been given by Melick (*J. Infect. Dis.* **21**:28-38, 1917).

Medical Education and State Boards of Registration

COMING EXAMINATIONS

ARKANSAS: Little Rock, May 13. Sec. Eclectic Bd., Dr. C. E. Laws, 803½ Garrison Ave., Ft. Smith; Sec. Regular Bd., Dr. T. J. Stout, Brinkley.

CALIFORNIA: San Francisco, June 23-26. Sec., Dr. Charles B. Pinkham, 904 Forum Bldg., Sacramento.

DELAWARE: Wilmington, June 17-19. Sec., Dr. H. W. Briggs, 1026 Jackson St., Wilmington.

FLORIDA: Jacksonville, June 16-17. Sec., Dr. W. M. Rowlett, Citizens Bank Bldg., Tampa.

GEORGIA: Atlanta and Augusta, June 5-6. Sec., Dr. C. T. Nolan, Marietta.

HAWAII: Honolulu, May 12. Sec., Dr. J. R. Judd, Beretania St., Honolulu.

ILLINOIS: Chicago, June 16-19. Supt. of Registration, Mr. F. C. Dodds, Springfield, Ill.

KANSAS: Topeka, June 17. Sec., Dr. H. A. Dykes, Lebanon.

MASSACHUSETTS: Boston, May 13-15. Sec., Dr. Walter P. Bowers, Room 501, No. 1 Beacon St., Boston.

MICHIGAN: Ann Arbor, June 10-12. Sec., Dr. B. D. Harison, 504 Washington Arcade, Detroit.

MINNESOTA: Minneapolis, June 3-6. Sec., Dr. T. S. McDavitt, 741 Lowry Bldg., St. Paul.

MISSISSIPPI: Jackson, June 24-25. Sec., Dr. W. S. Leathers, University.

MISSOURI: St. Louis, June 9-11. Sec., Dr. George H. Jones, State House, Jefferson City.

NATIONAL BOARD OF MEDICAL EXAMINERS: Philadelphia, June 2-7. Sec., Dr. J. S. Rodman, 1310 Medical Arts Bldg., Philadelphia.

NEW JERSEY: Trenton, June 17-18. Sec., Dr. Alex. MacAlister, 438 E. State St., Trenton.

NEW YORK: Albany, Buffalo, New York and Syracuse, May 20-23. Mr. George M. Wiley, director, Exam. and Inspections Div., State Edu. Bldg., Albany.

NORTH CAROLINA: Raleigh, June 23. Sec., Dr. H. A. Royster, 423 Fayetteville St., Raleigh.

OHIO: Columbus, June 3-6. Sec., Dr. H. M. Platter, State House, Columbus.

SOUTH CAROLINA: Columbia, June 10. Sec., Dr. A. Earle Boozer, 1806 Hampton St., Columbia.

TENNESSEE: Knoxville, Memphis and Nashville, June 13-14. Sec., Dr. A. B. De Loach, Exchange Bldg., Memphis.

TEXAS: Austin, June 24-26. Sec., Dr. M. F. Bettencourt, Mart.

VERMONT: Burlington, June 26-28. Sec., Dr. W. Scott Nay, Underhill.

VIRGINIA: Richmond, June 17-20. Sec., Dr. J. W. Preston, 215 S. Jefferson St., Roanoke.

WISCONSIN: Milwaukee, June 24-26. Sec., Dr. J. M. Dodd, 220 E. 2nd. St., Ashland.

GRADUATE MEDICAL INSTRUCTION IN LONDON

The *British Medical Journal* of March 8, 1919, contains an editorial referring to an article by Sir Wilmot Herringham on medical education in London.

This article compares the "hopelessly deficient" postgraduate instruction in London with the "attractions" Vienna and Berlin possessed when they were drawing medical graduates from all over the world. These attractions of Vienna and Berlin in substance are given as follows:

(*a*) Coaching classes, which are given by men who are unquestionably well qualified since they are those who are in line for professorial chairs.

(*b*) Opportunities for gaining skill in the use of clinical instruments, such as the laryngoscope, otoscope, ophthalmoscope, etc.

(*c*) The possibility of obtaining an appointment as assistant to a professor of surgery, thereby gaining a large experience in operations.

(*d*) The chance of obtaining a place in a professor's laboratory, where, although the work might be monotonous, he would learn the methodical system of work for which the German was justly famed.

(*e*) The uniformly instructive lectures given by the professors (as compared with the average lecture given in London).

The enumerating of these "attractions" in Vienna and Berlin was evidently intended to reveal in contrast the needs of postgraduate education in London.

A special difficulty in the development of graduate education in London is shown to be the development in the middle of the nineteenth century of a large number of special hospitals, due to the fact that "specialism was disdainfully regarded by most teachers in the medical schools." The writer shows that "something was due to the public, who insisted on having specialists," but that every department of medicine was growing so complex that "no man could any longer pretend to be expert in them all." The consequence was that all large general hospitals had special departments and the Royal Society of Medicine had thirteen special sections. The editorial states, however, that there has come to be a general recognition of the need for specialization in practice, the result of which is "that the chief special hospitals are now largely staffed by men who are members also of a staff of a school hospital."

It is stated that in making plans for postgraduate courses, which are about to be resumed in Edinburgh, the committee has arranged to pool the hospital resources. The courses will be held at four large hospitals, and "the members will hold temporary appointments as assistant demonstrators in the practical courses and as clinical assistants in the wards and special hospitals."

In the emergency facilities provided in London through a fellowship of medicine, all medical school hospitals are included, as well as a like number of special hospitals. "The instruction referred to will include general courses and special courses." By the latter is meant courses in certain classes of disease, for example, disorders of digestion. "After attending a special course the graduate would be eligible for research work in the subject or to hold a post as clinical assistant," a plan not hitherto commonly carried out. Attention is called also to "the necessity of opening clinical appointments in London to stranger graduates," and "the establishment of a special graduate hospital to which all the resident and junior appointments would be held by the visitors to London" is favored. The editorial urges that three points be more fully considered, namely, (*a*) the desirability of arranging graduate courses at teaching hospitals; (*b*) the best way of utilizing special hospitals, and (*c*) the opening of clinical appointments to graduates. The editorial concludes that "the proposed graduates' association will need a building in central London containing offices for the secretarial staff, a library, and recreation and luncheon rooms. At this center the business of the proposed permanent association would be conducted, fees would be received and paid and information supplied to graduates attending or desiring to attend the courses."

Case Records and Their Use

Two pamphlets dealing with hospital case records and forms have been issued recently by the American College of Surgeons.[1] One emphasizes the importance of keeping proper records in a hospital, explains in detail why they are important and gives suggestive outlines showing what might be included in such records. Records are shown to be the best means by which an accurate check can be kept on the various members of the hospital staff and by which faulty methods may be traced and promptly corrected. The other pamphlet suggests forms of blanks which may be used for recording the personal history and the physical examination, forms to be used in the various specialties, blanks for recording laboratory findings and treatment, and a temperature chart. A form for a summary card is also suggested, which is intended to be filled out after the patient has left the hospital, and by means of which the end results may be reviewed without revealing the name of either the physician or the patient. These pamphlets should have a wide distribution among hospitals and will doubless be of much value.

District of Columbia January Examination

Dr. Edgar P. Copeland, secretary of the Board of Medical Supervisors of the District of Columbia, reports the oral and written examination held at Washingon, Jan. 14-16, 1919. The examination covered 16 subjects and included 80 questions. An average of 75 per cent. was required to pass. Seven candidates were examined, all of whom passed. Four candidates were licensed through reciprocity. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
George Washington University (1916) 82.4; (1917) 75.5, 83.5; (1918) 81; 86.4.		
University of Maryland	(1918)	85.7
Hahnemann Med. Coll. and Hosp. of Philadelphia	(1918)	80.2

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
Georgetown University	(1898)	Virginia
Howard University	(1912)	Virginia
University of Maryland	(1913)	Georgia
Starling Medical College	(1892)	Ohio

Book Notices

WAR SURGERY OF THE ABDOMEN. By Cuthbert Wallace, C. M. G., F. R. C. S., M.B., Surgeon St. Thomas' Hospital. Cloth. Price, $3 net. Pp. 152, with 26 illustrations. Philadelphia: P. Blakiston's Son & Co., 1918.

This little monograph of 150 pages contains "the experiences of abdominal surgery of a sector of the battle line over a period of thirty months" and "is founded on the practice of many surgeons working under different conditions and in different hospitals. The personal equation and influence of locality have thus been largely eliminated."

There is really little fundamental difference between war surgery and peace surgery. "It is a question as to whether war conditions allow the surgeon to apply the principles that he knows to be right." "War surgery is largely concerned in overcoming adverse circumstances and in striving to make war conditions as much like peace conditions as possible." War does not change the principles of surgery, it only changes the conditions under which the principles must be applied, and as the conditions are often such as to make it impossible to follow the best surgical methods, one must learn to do the best one can under the conditions present, and that is war surgery.

The question as to whether wounds of the abdomen should be operated on or not is thoroughly discussed. The evidence presented shows conclusively that it is not so much a question of procedure as it is a question of time and conditions. Because a man recovers after a bullet wound traversing the abdomen is no evidence that any of the hollow organs were injured. On the contrary, the fact that he recovered is almost certain evidence that none of the hollow organs was injured. That a bullet may traverse the abdominal cavity in any direction and not injure the hollow viscera is well shown by the remarkable chart, Figure 6. This chart ought to convince anyone of the necessity of being most conservative in claiming that bullet wounds of the intestinal tract may heal spontaneously. Patients that recover spontaneously after a bullet wound of the stomach or intestine are exceedingly few indeed. "Experience has shown the wisdom of operating as a routine measure, and it is now mainly a question of excluding the cases on which it is best not to operate.

"On the whole 'look and see' is a better maxim than 'wait and see.'"

After discussing the subject in general, wounds of particular organs are taken up more in detail. Many interesting tables showing number, location, and character of wounds, with results of treatment, are appended.

THE HEARTS OF MAN. By R. M. Wilson, M.B. Cloth. Price, $2. Pp. 182, with 117 illustrations. New York: Oxford University Press, 1918.

Quoting from the preface, we find "the prime object of the book is to encourage investigation into certain phenomena of the circulation and of the nervous system which have not hitherto been clearly investigated from the purely clinical standpoint—for example, the mechanism of breathing in effort and at rest, the meaning and effect on the general circulation of the great blood lakes of the skin, abdomen and lungs." Certain new notions the result of clinical observation are advanced in the sixteen chapters. These deal with such topics as reaction breathing, the function of the abdominal wall in reaction breathing, rest breathing, the ductless glands and the reaction state, the effects of epinephrin, the vagus—nerve of diastole, etc. Many of these ideas will need confirmation before they can be generally accepted but they are suggestive, stimulating and well worth careful consideration.

Rulings and Distinction as to Liability of Hospital

(Morton v. Savannah Hospital (Ga.), 96 S. E. R. 887, 888)

The Supreme Court of Georgia, in answering questions certified to it from the court of appeals, holds, first, that the Savannah Hospital, chartered by the general assembly and invested with "all the powers, rights, privileges and liabilities incident to a corporation," is authorized and empowered to conduct an institution eleemosynary in character for the public benefit. It was not the intention of the legislature that the business so conducted might be for the pecuniary gain or benefit of its managers, officers or others.

The next question was: If the intention of the legislature was to charter said corporation for charitable purposes only, would such intention, as expressed in or to be gathered from the charter itself, fix and determine its nature and character as an eleemosynary institution, in a suit brought against the corporation by a patient on account of the alleged carelessness and incompetence of a nurse and of a servant employed by the hospital, and on account of the failure of the hospital and of the superintendent under whose charge it was operated to remove such incompetent nurse after her incompetence became known and prior to the injury, notwithstanding allegations in the petition of the plaintiff in said action that "the said Savannah Hospital, conducted at Savannah, Ga., a hospital for pecuniary gain, and the greater portion of said hospital was set aside by its officers for the reception and treatment of patients who were charged for its services and who paid for the same"? The answer is that the intention of the legislature in chartering the Savannah Hospital is fixed and determined by the acts of the general assembly. In a suit brought against the corporation by a patient, as stated in this question, the charter provisions are controlling, notwithstanding allegations in the petition of the plaintiff as stated above.

Then the question was propounded whether, if the Savannah Hospital was chartered as a charitable institution, but nevertheless the greater portion thereof was set aside by its officers and superintendent for the treatment of patients who paid for the services they received, would this state of facts render the corporation liable to one who entered the hospital as a patient under an agreement to pay a stated sum for all necessary care, nursing, attention, control, oversight and medical treatment suitable or appropriate to her condition, for any injuries resulting to such patient on account of the negligence, carelessness or incompetence of the officers and agents of the corporation? The answer is that, under circumstances as just enumerated (although the hospital is a charity, and the general rule is that charitable funds are not to be depleted by subjection to liability for negligence), the corporation would be liable; but a recovery would be limited to the extent of income derived from treatment of patients who paid for services. With the exception just stated, an incorporated hospital, primarily maintained as a charitable institution, is not liable for the negligence of its officers and employees, unless it fails to exercise ordinary care in the selection of competent officers and servants, or fails to exercise ordinary care in retaining such officers and employees.

Where a patient in such an institution is not the recipient of its charity, but is able to pay and does pay for the services, and is injured on account of carelessness, negligence or incompetence of an officer or employee of the institution, the corporation is liable therefor; but the judgment can subject only funds derived strictly from noncharitable pay patients, and for this purpose the petition need not allege that the corporation failed to exercise ordinary care in the selection of its officers and employees or in retaining them. A judgment so recovered will not subject funds in trust for charitable purposes, unless the petition alleges that the corporation failed to exercise ordinary care in the selection of its officers and employees, or in retaining them.

Following the decision by the supreme court is one by the Court of Appeals of Georgia, Division No. 1 (on page 888), which says that, under the answers made by the supreme court, it appears that the trial judge erred in sustaining a general demurrer to the plaintiff's petition, and therefore his judgment must be reversed. Moreover, anything in the decision in *Medical College* v. *Rushing,* 1 Ga.App.468, 57 S. E. 1083, which may be in actual conflict with the holdings of the supreme court in this case, will not be followed.

Fraud in Hypnotic Treatment of Insane Delusions

(Roesler v. Shastri (Wis.), 169 N. W. R. 282)

The Supreme Court of Wisconsin reverses a judgment that was rendered on a verdict directed for the defendant, and remands for a new trial this case in which the plaintiff sought by replevin to recover a bank draft for $950 alleged to have been obtained from him through fraudulent representations by the defendant. The court says that the plaintiff was a farmer whose wife had been suffering from insane delusions for thirteen or fourteen months and had been at a hospital three times. He engaged the defendant to treat her. He testified that the defendant held himself out as a doctor, and was called such, and it appeared that the defendant had used the title M.D. on his letter heads; that he represented that he could by the use of hypnotic influences cure the plaintiff's wife, but that he must first destroy her mind, and make it like a child's and then build it up again. He assured the plaintiff that he could cure her, but he had to have $50 per day. At the end of twenty days the defendant said she was cured 50 per cent., but that he could not stay longer, and was given the draft and $50 in cash. It appeared that the defendant was a native of India; that he had been educated as a physician in the University of Binjab, and had pursued some medical studies in Chicago and Los Angeles, obtaining a medical degree from the latter school; but he had not been licensed to practice in the United States. He claimed that he used hypnotic suggestion only in his treatment of the plaintiff's wife, and denied that he had said that he could cure her.

The supreme court thinks it was error to direct a verdict in this case. It was a question for the jury to say whether or not plaintiff was deceived by the defendant. The jury had a right to believe the plaintiff's testimony, and to draw the conclusion therefrom that he was defrauded of his money. He had an insane wife; that he was anxious to cure her was evidenced by the fact that he willingly paid $50 a day in an effort to do so. He was undoubtedly ignorant of what could or could not be done through mental healing or hypnotic suggestion. There is a sharp conflict of views on that subject by those who have given it study and attention. That he did not know was not strange. Neither was it strange that he was unable to diagnose the exact or relative condition of his wife's mind at the time the draft was delivered. He had been told that her mind must first be wholly destroyed, and then built up, and he evidently believed that. The law protects the ignorant and credulous, as well as the wise and wary. He was told by the defendant, when the latter received the draft, that her mind was 50 per cent. cured, and that the nurse could take care of her afterward. We employ doctors to diagnose disease, and to cure it or direct us what to do to effect a cure. That is their profession. When they give advice, the patient is justified in following it, unless it is so palpably contrary to sense or human experience as to be disbelieved by every one.

There was sufficient evidence in this case to warrant the jury in finding that the defendant held himself out as a doctor. A letter from him to the nurse, which was shown to the plaintiff, with the heading "K. D. Shastri, M.D." and was signed "K. D. Shastri, M.D." He was called doctor, and made no protest. The fact that he was not required (in Wisconsin) to be licensed to heal by mental science or hypnotic suggestion was immaterial on the question of actual fraud. An unlicensed person may make fraudulent representations.

The plaintiff should have been permitted to show by other doctors, if he could, that the treatment given his wife by the defendant was injurious, and not beneficial. It was true that the defendant's counsel on the trial admitted that she was neither cured nor benefited. But the plaintiff's offer went farther. He offered to prove that she had been injured by the treatment. Such proof was pertinent on the issue of fraud and should have been admitted.

Claim was made that since, in delivering the draft to the defendant, the plaintiff parted with the legal title thereto, he could not maintain replevin to recover it; but this court has several times negatived that claim, and held that replevin will lie to recover goods obtained by fraud.

Witness Fees Under Workmen's Compensation Act

(Nelson v. Industrial Insurance Department (Wash.), 176 Pac. R. 15)

The Supreme Court of Washington modifies, as to the fees allowed a medical witness, a judgment that granted an award as for permanent partial disability for practical total loss of vision in the left eye. The court says that the trial judge allowed a fee of $45 to one of the medical witnesses who came from Portland, Ore., to attend the trial. It was contended that this allowance was proper under the provision of the statute that the court may allow an attorney's fee, "and the fees of medical and other witnesses and the costs shall be payable out of the administration fund, if the accident fund is affected by the litigation." But there is no provision of the law that will warrant the payment of extraordinary fees to expert witnesses as such; and the supreme court thinks that it is hardly within any rule of statutory construction to say it was the intention of the legislature to leave the fixing of witness fees to the discretion of the court. Being dependent on the statute, costs and witness fees are never to be allowed in the discretion of the trial judge, in the absence of a positive or permissive statute. It will be observed that the only discretion given to the court in the allowance of costs on appeal from an order of the department is that the trial judge may fix a reasonable attorney's fee and "such (reasonable) fee, and the fees of medical and other witnecesses . . . shall be payable," etc., plainly indicating that it was the intent of the legislature to associate medical witnesses with "other witnesses" and not with the attorney whose service is independent of the witnesses, and for which no fee is provided by law. This court has heretofore refused to extend the terms of this statute by construction. It follows that the judgment of the lower court should be modified to this extent.

Requirements for Revocation of Licenses

(Blunt v. Shepardson et al. (Ill.), 121 N. E. R. 263)

The Supreme Court of Illinois says that the power given by the civil administrative code to the department of registration and education to revoke a license to practice medicine is not arbitrary. The department cannot act except for cause shown, on notice and hearing and with an opportunity to defend. Its power to revoke the license of a medical practitioner cannot be exercised except on the action and report in writing of a majority of the five reputable physicians licensed to practice medicine and surgery in this state designated from time to time by the director of registration and education for that purpose. According to the petition in this case, no such report in writing was ever made; at least, no notice was ever given to the petitioner. He was simply advised by letter that reports of unprofessional conduct on his part had reached the board and told verbally that it had been reported to the board that he had been found guilty of violating the Harrison drug act. There was no charge, no hearing, and the letter announcing the revocation of his license did not state for which of the reasons mentioned in the medical practice act his license had been revoked or whether for any or no reason. The evidence of the granting and revocation of licenses cannot rest in parol, or verbal statements. The record must be preserved, and it is essential to the validity of an order revoking a license that it shall show the facts essential to the jurisdiction of the department. On the showing made by the petition in this case, a writ of certiorari should have been awarded to bring before the court the record of the proceedings of the department of registration and education, and its issuance is directed.

Physical and Mental Condition of Delinquent Boys. C. P. McCord, Albany.—p. 101.

American Journal of Diseases of Children, Chicago

May, 1919, **17**, No. 5

*Cystoscopic Study of Urologic Conditions in Children. F. Hinman, San Francisco.—p. 306.
Studies on Mammary Gland: V. Effects of Inanition on Developing Glands in Male and Female Albino Rats from Birth to Ten Weeks of Age. J. A. Myers, Minneapolis.—p. 311.
Recovery of Normal Weight in Various Organs of Albino Rats on Refeeding After Underfeeding from Birth for Various Periods. C. M. Jackson and C. A. Stewart, Minneapolis.—p. 329.
Measurements of 250 Full-Term New-Born Infants. R. Taylor, Minneapolis.—p. 353.

Cystoscopy in Children.—The findings of twenty-six cystoscopic studies done on children are reported by Hinman. The youngest patient was a girl, 11 months of age. Of twelve cases of pyuria in girls, six were acute or subacute infections and six chronic. In three of the acute and three of the chronic cases, infection was limited to the bladder; microscopic and cultural studies of the catheterized kidney urines were negative. There was cystoscopic evidence of bladder inflammation in all twelve cases. Infection was confined to the left side in two and was bilateral in four of the six pyelites. The total phenolsulphonephthalein was normal in all. *B. coli-communis* was cultivated from the urine in all but one case in which a pure staphylococcus was secured. In all of the ureteral catheterizations silver nitrate in strengths of 0.25 to 2 per cent. was used as pelvic lavage before the withdrawal of the catheters. Calculus formation was recognized four times, left nephrolithiasis in a boy of 4 years (with congenital posterior urethral valve), large urethral calculus in a boy of 5 and large bladder stones in boys of 3 and 4 years, respectively. Acute hemorrhagic nephritis occurred in two girls of 6 and 10 years. Urologic investigation with diagnosis was made of a large retroperitoneal sarcoma, a large hypernephroma and an insufficient horseshoe kidney, all of these patients coming to operation or necropsy. Three small boys, aged 3, 4 and 5 years, with symptoms of prostatism and residuals of 80, 320 and 110 c.c., have been subjected to examinations (the youngest required external urethrotomy), which revealed valvelike obstructions in the posterior urethra. Hinman emphasizes that a complete urologic study (cystoscopy and ureteral catheterization) is technically possible in children irrespective of sex or age, and that he has not met with any untoward consequences or disagreeable complications. The results in every instance have justified the procedure.

Formation of Bone by Osteoblast.—The neoplastic theory of bone formation is endorsed by Ely. The osteoblast is the bone-building cell. Neither periosteum nor marrow is necessary for bone formation; neither of them forms bone, in the proper meaning of the word. In each tissue the conditions are right for bone formation. The materials are there, and, given the stimulus, physiologic or pathologic, bone will be manufactured out of the fibrous tissue of the periosteum, or out of the fibrous or cartilaginous tissue in the marrow. The presence of bone is to a certain extent a stimulus for further bone formation. The true marrow cells, the characteristic marrow cells, probably have no function in bone building whatever.

Repair of Cranial Defects with Rib Transplants.—In the cases reported by Wilson, pieces of rib and cartilage were used for transplants into cranial defects according to the method used by Primrose of Toronto.

Lesions Observed in Operations for Old Spinal Cord Injuries.—Twenty operations were done by Elsberg for spinal lesions due to old fractures or wounds of the vertebral column. Of these patients, eight were completely relieved of their symptoms, and six were greatly improved. In six there was little or no improvement.

Diagnosis and Therapy of Bone Typhoid.—By means of bacteriologic examinations of bacteria obtained from isolated foci, Bohmansson believes he has succeeded in proving the typhoid nature of typhoid complications in the bone system when no clinical support for such a diagnosis existed. He also believes that multiple typhoid bone foci are probably commoner than is shown by statistics. Systematic roentgenray examination is urged for the entire skeleton in isolated bone foci, in order to determine the treatment, although the diagnosis can be made with certainty only by means of bacteriologic examination of the foci discovered. Single foci are quickly and securely accessible for direct operative treatment. Autogenous therapy was tried by Bohmansson in one case without discomfort to the patient, and with apparently good results. There seems to be good reason for continued experimentation in this direction.

Fatty Hernias.—Twenty-three cases of fatty hernia recorded in the literature are reviewed by Hale, and he adds two personal cases. The diagnosis of these cases seems to be difficult, but treatment is the same as that of an ordinary hernia.

Anuria After Unilateral Nephrectomy.—Frank is of the opinion that not only in calculous anuria, but in the occasional suppression which follows nephrectomy, the suppression is brought about entirely through circulatory disturbances. Hence, the term reflex anuria, as indicative of some nerve connection or nervous reflex, is a misnomer. The active arterial congestion, the vascular overfilling, particularly on the arterial side, Frank says, accounts for the diminution in the urinary output in practically all cases of unilateral nephrectomy during the first few hours. As soon as the circulation on both sides in the kidney is equalized, then there is an increase in the urinary output and the kidney gradually accommodates itself to performing the function of both organs.

Adhesive Plaster Method for Dressing Granulating Wounds.—This procedure is applied by Beck in all types of granulating wounds, whether these be due to ulceration, burns, or trauma, and especially wounds produced by surgical operations. The most important field for this method, he believes, is found in the demand for skin regeneration over denuded surfaces produced in the skin sliding operation for empyema. This method is now widely employed in the treatment of the apparently hopeless cases of chronic suppuration of bones and joints, empyema, and lung abscess. The technic consists in applying strips of plain or zinc oxid adhesive plaster along the edges of the granulating wound. These strips, from one-half to three-quarters inch in width, must be so adjusted that they cover both margins, that of the skin and that of the granulating wound. This leaves the center of the granulating surface exposed for absorption of the wound secretions by a dry, sterile dressing. Twenty-four hours later the dressing and adhesive plaster are carefully removed. It will be found that along the margin of the skin there has now formed a bluish-gray border, about 2 or 3 mm. in width. This bluish-gray border represents the new growth of epithelial cells. The wound is dressed with dry gauze, which is left on for twenty-four hours, followed on the next day by another application of adhesive plaster. This procedure is repeated until the entire granulating surface is covered with epithelial growth. All necrotic tissue must be allowed to slough off, so that the base of the wound is clean. The wound must never be rubbed with gauze, as this would be apt to destroy the new epithelial cells.

Intravenous Injection of Gum Salt Solutions.—A large number of preparations of the gum salt solution made at the central laboratory of the U. S. Army Medical Department and used in resuscitation work at the front were subjected to toxicity tests in guinea-pigs by De Kruif. The aim of the experiments was to discover whether these solutions might possess the "equilibrium disturbing" effect that certain substances in the colloidal state show when injected into the circulation. With one exception no effects of an anaphylactic nature were observed. Slight symptoms of various kinds which followed the injection of massive doses of certain samples were of so little importance that they could be disregarded. The exception mentioned was that of a sample contaminated with *Staphylococcus aureus* and an unidentified bacillus. Severe effects followed the injection of this preparation. One guinea-pig succumbed with typical anaphylactic symptoms. This animal was not a normal one, but was shown at necropsy to be pneumonic. Normal harmless gums seeded with the organisms isolated from the preparation just described showed some increase in toxicity, which was not, however, as marked as that of the original sample. Out of thirty-five samples tested for sterility, three were found to be contaminated. This is a serious indictment of methods of control of sterility used by those making the gum solutions. Attempts to produce a toxic state in gum solutions by subjecting them to cold failed. Attempts to make normal rat and guinea-pig serums "anaphylatoxic" with various samples of gum did not succeed. This furnishes important confirmatory evidence of the harmlessness, as far as the anaphylactic effect is concerned, of the gum solutions.

Treatment of Burns by Sodium Bicarbonate Solution.—McDonald has found by experience that in the first aid care of extensive burns, the dressing with gauze soaked in 10 per cent. or stronger sodium bicarbonate and kept moistened is the simplest and gives greatest comfort. This is preferable to attempts at a more complicated technic. Morphin should be used to give rest but must be administered with care since there is often severe reaction and depression and the drug may do harm. Treatment of shock with posture, heat, hot drinks and stimulants may be necessary. Paraffin is much preferable to gauze with oily dressings and should be substituted as soon as possible, at least within thirty-six hours. With the use of the air pump and atomizer the method can be simplified and rendered quite painless; dressings on gauze should be abandoned. Dichloramin-T in oil is painful and of slight value. If there is extensive slough, wet dressings or antiseptic powders are preferable. The use of adhesive strappings over the raw surface is highly satisfactory and simplifies the treatment, since dressings may be extended to two or three days. The general conditions of the patient must be carefully followed and built up by stimulants, tonics or transfusions. Skin grafting is rarely necessary, nor does it offer much advantage to the healing with paraffin or adhesive.

Suppurating Cyst of Urachus.—For ten years, Ward's patient, a woman, aged 44, had had considerable discomfort from moisture in the umbilicus, which at times was very offensive, smelling like urine. She had to wear a cloth pad over the navel all the time, and every day had to cleanse the parts to prevent irritation. She was unable to walk upright on account of the pain and swelling in her navel. Her sleep was broken by severe contracting pains in the umbilical region. She had become very much depressed mentally, and had no inclination for food. On examining the abdomen, Ward found a tumor mass, round in shape, about the size of an orange, which was just below the navel, and apparently in direct contact with its lower border. The umbilical wall was somewhat elevated and reddened. The floor of the umbilicus was bathed in thin, watery pus, and an odor of urine was present. There were no signs of any abdominal complications. At operation the walls of the cyst had a fibrous, rough, gritty feel. On entering the cyst cavity, about 8 ounces of a yellowish, very fetid pus exuded. At the umbilical end of the cyst, was an oval-shaped mass, about 1½ inches long and three-quarters inch wide, and about one-half inch thick. The removal of this oval mass disclosed a very small aperture, opening directly on the floor of the umbilicus. This opening admitted the point of a fine probe. Ward swabbed out the cavity with tincture of iodin and packed with iodoform gauze. The patient began to improve in health almost immediately; the wound healed rapidly and in two weeks she was discharged.

Pneumonia and Empyema. H. Gray, Camp Devens, Mass.—p. 475.

Postinfluenzal Alopecia.—Twenty-five consecutive cases of alopecia following influenza are analyzed by Ayres. He claims that alopecia is a not infrequent sequel of influenza, occurring commonly about two or three months after the onset of the influenza, but occasionally during convalescence. The alopecia is usually of the diffuse type, although in one of the hospital cases and one private case the lesions were patchy, and, without a history of influenza, might have been diagnosed alopecia areata. Most of the cases which Ayres has seen have been females, twenty-one of the twenty-five consecutive cases. All of the twenty-five patients are under 36 years of age. The ultimate aim in treatment is to promote a healthy circulation of the scalp. This is attained most easily by massage, with the head lowered; by avoidance of obstruction to the main vessels of supply to the scalp by padding the hat band at appropriate points; by stimulating lotions; by keeping the scalp clean.

*Keratolysis Exfoliativa. J. E. Lane, New Haven, Conn.—p. 223.
Lichen Acuminatus. S. Feldman, New York.—p. 226.
*Psoriasis and Diet. W. A. Pusey, Chicago.—p. 240.
Lichen Planus in Two Brothers. D. W. Montgomery and G. D. Culver, San Francisco.—p. 242.
Dermatology in U. S. Army: Report of Dermatologic Department, Camp Travis, Texas, for 1918. W. H. Guy, Pittsburgh.—p. 245.

Keratolysis Exfoliativa.—A considerable number of cases of this affection have come to Lane's notice. All of them were seen in the summer and all cleared up with the approach of cool weather. In several cases seasonal recurrence had been noted. The mild cases were favorably influenced by fatty applications. In a marked case the application of a mild dose of roentgen ray brings about a prompt cure.

Psoriasis and Diet.—That a restricted protein diet extending over many years may be accompanied by psoriasis is shown in Pusey's case. When the patient was a child 3 years old, she was thrown into great excitement by seeing a chicken killed, and as a result developed a complete antipathy for animal foods. Until she was 19, she ate absolutely no meat, fowl, fish, milk or eggs, except such milk and eggs as she received in breads. For the last four years she has eaten a very small amount of meats, nothing but pork chops and beef; she eats sparingly of these and only once a day, her reason being she does not care for meats. She has never eaten eggs, milk, fish or shell-fish. She has tasted eggs and milk, but as far as she knows, she has never tasted fish. She is very fond of gravies and her diet in other respects is well rounded. Pusey is convinced that her intake of animal protein is a physiologic minimum, and she is not a heavy eater of leguminous vegetables, yet she had a clear case of psoriasis.

Journal of Medical Research, Boston

March, 1919, **39**, No. 4

*Paratyphoid-Enteritidis Group. VI. Separation of Distinct Paratyphoid Group Among Strains of Rodent Origin. C. Krumwiede, Jr., E. Valentine, and L. A. Kohn, New York.—p. 449.
*Susceptibility of Naturally Nephropathic Animals to Acute Mercuric Chlorid Intoxication. W. deB. MacNider, Chapel Hill, N. C. —p. 461.
*Bacillus of Colon Group Isolated from Cystitis Urine. S. Niwa, Cambridge, Mass.—p. 469.
*Action of Benzol: V. Diphasic Leukopenia as Polynuclear Amphophile Phenomenon (Rabbit). H. G. Weiskotten and H. S. Steenland, Syracuse.—p. 485.
Rocky Mountain Spotted Fever in Domestic Rabbit. N. C. Foot, Cambridge, Mass.—p. 494.

Paratyphoid-Enteritidis Group.—Of fifteen guinea-pig strains of the paratyphoid-enteritidis group, thirteen were alike in their agglutination reactions. This apparent identity was further verified by agglutinin absorptions. Two strains from mice and one each from a rabbit and from a cat as shown by agglutinin absorption were identical with this group of thirteen guinea-pig strains. A distinct paratyphoid group of bacilli is encountered therefore in spontaneous infections from laboratory animals, especially rodents. Some of the strains from mice and guinea-pigs do not fall into the above group. Others belong agglutinatively to the *B. enteritidis* group. Evidently the host origin of a culture is not necessarily an index to its biologic position, and the classification of strains according to origin, as *B. typhi-murium* or *B. pestis-caviae*, is not justified. None of the rodent strains studied belongs to either the *B. cholera-suis* or *B. paratyphosus* "B" groups.

Acute Mercuric Chlorid Intoxication.—Fourteen naturally nephropathic animals were intoxicated by mercuric chlorid. From the results obtained by MacNider, it is evident that the kidney of the naturally nephropathic animal is very susceptible to the toxic action of mercuric chlorid, and that the toxic effect of mercuric chlorid, so far as the kidney is concerned, has been associated with the development of an acid intoxication. The severity of the acute changes occurring in the kidney have shown a correlation with the severity and duration of the acid intoxication.

Bacillus of Colon Group Isolated from Cystitis Urine.—The organism isolated by Niwa from cystitis urine is a member of the colon group which is not named, but according to McConkey is to be classified in Group II, according to Jenson-Bahr's list in Subgroup G of *B. coli*, and to be located as No. 227 of Group XV on the list published by Bergey and Deehan, 1908. In the fermentation tests with different sugars, this organism fermented dextrose, lactose, dulcite, mannite, maltose, raffinose, adonite and inulin with the production of acid and gas without any delay, whereas it did not ferment saccharose at all. Of those sugars the gas production through this organism was the strongest in mannite and maltose, and then in dulcite, lactose, dextrose and adonite, while in raffinose and inulin it was the weakest. The acidity produced by this organism in those sugar mediums was most marked in mannite, maltose, dulcite, and lactose, and then in dextrose and adonite, while in raffinose and inulin it was only feeble. This organism proved to be pathogenic and pyogenic to animals, such as the mouse and guinea-pig. The serum of the patient in question showed a strong agglutinating power to this organism. Hence Niwa suggests that this organism may be the active cause of his case of cystitis.

Action of Benzol.—The diphasic character of the leukopenia following subcutaneous injections of olive oil benzol mixture in rabbits Weiskotten and Steensland mention is mainly a polynuclear amphophile phenomenon and only to the extent of about one sixth a small mononuclear phenomenon.

*Case of Balantidium Coli Dysentery. C. W. Mason, Chieng Rung, Yunnan, China.—p. 137.

Balantidium Coli Dysentery.—Human balantidiosis is said by Mason to be less rare than is usually supposed. However, on account of the infrequent appearance of the parasites in the stools of infected persons and the absence of clinical symptoms in many of the cases, it is probable that parasitization with *Balantidium coli* is frequently overlooked in the routine examination of stools. Thirteen cases have been observed in the Philippine General Hospital. In the Bilibid Prison, thirty-five cases have been found in the last two and a half years, an average of more than one a month. *Balantidium coli* produces bacteriologically sterile abscesses in the submucosa of an infected intestine. The latency prevalent in balantidiasis of man is due chiefly to the fact that the patient, although parasitized, is not infected with *Balantidium coli*, but is in part due to the chronicity of the ulcerative process in infected cases.

Journal of Urology, Baltimore

*Experimental Nephropathy Produced by Organo-Mercury Compound of Phenolsulphonephthalein. J. E. Burns, E. C. White and J. G. Cheetham, Baltimore.—p. 1.
*"Forage de la Prostate" in Treatment of Prostatic Hypertrophy. G. Luys, Versailles.—p. 17.

Experimental Nephropathy.—This study was undertaken with the idea of producing acute and chronic renal lesions of varying degrees of intensity and of determining whether or not lesions could be produced more nearly resembling those found in human beings in the different types of nephritis than have been heretofore experimentally accomplished. The drug synthesized by Burns and his associates, and made use of in their experiments, is tetra-oxymercury phenolsulphonephthalein. It is prepared by the action of an excess of mercuric acetate on phenolsulphonephthalein and it contains 63 per cent. of organically bound mercury. The renal lesions produced by this drug resemble quite closely those found in the different types of nephritis in human beings. The lesions in the acute type are mainly tubular, although some slight glomerular changes have been noted. In the chronic type the most striking change was the increase of interstitial tissue both in the glomeruli and between the tubules, together with areas of tubular obliteration and of glomerular fibrosis. Chemical examination of the blood and urine showed results quite analogous to the type of lesions produced. This organo-mercury compound has, as was anticipated, produced these marked renal lesions without producing lesions elsewhere in the body in the chronic type, and in the acute type the lesions other than renal have been insignificant and in no case responsible for the death of the animal.

"Forage de la Prostate" in Treatment of Prostatic Hypertrophy.—This treatment has as its object the gouging out of a tunnel from the interior of the gland through the natural channels, in such a way as to permit free escape of urine. "Forage de la Prostate" a surgical intervention carried out under direct ocular observation was originated by Luys in 1914. A direct vision cystoscope and the galvanocautery are used. Luys says that the method has given absolutely satisfactory results. These good results are durable as well as immediate.

*Pneumonia and Empyema at Camp Merritt in Winter of 1917-1918. E. H. Schorer, F. D. Clark, R. Sanderson, J. D. Dickson, and F. M. Huntoon, Hoboken.—p. 673.
Influenza Aboard Man-of-War. F. M. Harrison, U. S. N.—p. 680.
Analysis of Two Hundred and Sixteen Industrial Accidents. C. Scheffer, Boston.—p. 685.
Scopolamin-Morphin in War Surgery. C. W. Strobell, New York.—p. 687.

Pneumonia and Empyema at Camp Merritt.—Pneumonia of three types, lobar, bronchopneumonia, and combinations of the two, were observed by the authors at Camp Merritt. Many of the cases were what MacCallum, Cole, and their co-workers have called interstitial bronchopneumonia, but of these very few followed measles or other contagious diseases. Empyema was the most frequent and serious complication. Of 181 pneumonia patients whose sputum was examined, eighty-one had fluid in the chest; and of these, fifty-six had a purulent pleural exudate. Hemolytic streptococci were found in 51.9 per cent. of the pneumococcus sputums, 53.7 per cent. of the pleural exudates, and 70.4 per cent. of the purulent pleural fluids. Thirty-four per cent. of straight pneumococcus pneumonias were complicated by chest fluid and 25 per cent. by empyema; 26.3 per cent. of pneumococcus and hemolytic streptococcus pneumonias were complicated by chest fluid and 24.9 per cent. by empyema; 15 per cent. of pneumococcus and nonhemolytic streptococcus pneumonias were associated with pleural fluid and 7.5 per cent. with empyema; 26 per cent. of all pneumonias in which pneumococci played a part had chest fluid and 20 per cent. had empyema. Hemolytic streptococcus pneumonia was complicated in 37.3 per cent. of the cases by chest fluid and in 25.4 per cent. by empyema. In spite of the fact that in the 116 cases of pneumonia in which type pneumococci were found, twenty-two of the twenty-six empyemas were caused by hemolytic streptococci. Three empyemas caused by pneumococci were found in patients in whose sputum no pneumococci were found. The authors believe that the hemolytic streptococci are seldom the primary cause of pneumonia, but that usually they assume an important and principal part in the final result of the cases of pneumonia.

Some of the hemolytic streptococci, or at least a portion of the organisms, are bile soluble, this factor being precipitinogenic. According to ability to ferment different sugars, the hemolytic streptococci causing empyema may be divided in four groups. If these groups be accepted, there is further argument for the belief that the streptococci are not the primary cause of the pneumonia, but are secondary invaders. These streptococci have a large common group factor in producing precipitin, but also contains specific precipitinogenic groups. The authors maintain that in the treatment of hemolytic streptococcus empyema drainage is necessary, the time for this being determined by the condition of the patient. Active immunization by the injection of autogenous vaccine seems to be of value in some cases. In many hospitals routine leukocyte counting on the first and tenth days of pneumonia, and on the first, second, third and tenth days after operation for empyema, has proved to be of value. This does not preclude leukocyte counting at any other time if indicated.

Bacteriology of Recent Epidemic of Influenza at Seattle.—Thirty-seven cases were studied by Henry. Positive findings were obtained in eight. In six these findings were pneumococcus (four, Type IV; two, Type I); in one both streptococcus and *B. influenzae* and in one, the meningococcus. Blood cultures were made in thirty-one cases. In six apparently uncomplicated cases, pneumococcus Type IV was found once. In twenty-five cases complicated by bronchopneumonia, Type IV was also found twice in the blood stream. Four spinal fluids were examined from cases diagnosed as complicated by meningitis. Pneumococcus, Type I; pneumococcus, Type IV; and meningococcus, respectively, were found in three. The fourth was sterile and the patient subsequently recovered. Of two pleural exudates, one showed both a streptococcus and *B. influenzae*, and one pneumocuccus, Type I. The latter was the only case studied at necropsy and was a bronchopneumonia. The heart's blood in this case also showed the same organism.

Roentgen-Ray Demonstration of Injected Vascular System of Fetus. H. C. Orrin.—p. 322.

Examination of Appendix by Roentgen Rays.—While Spriggs does not advocate making a roentgenogram in any case of acute appendicitis, he does believe that the procedure is of great value in cases of chronic appendicitis, not only in cases in which suspicion had been cast on that organ, but especially in the subjects of vague abdominal symptoms of unknown cause. In many such cases Spriggs has been able either to demonstrate a normal appendix or to show that it was, or had been, the seat of disease. He gives a barium sulphate and buttermilk meal. Of the last 100 patients examined, the appendix appeared to be normal in forty, though one of these patients showed tenderness. In nineteen cases the appendix was reported diseased; the diagnosis was confirmed by operation in eleven cases. In twenty-seven, slighter abnormalities were found, such as appendical stasis (eighteen cases), kinking, fixation, partial obliteration or diminution of lumen. In the remaining fourteen, the appendix was not seen. In one of these cases operation was done and a constriction found at the base of the appendix. An account is given of the methods and manipulations which have been found useful in the examination of 300 appendixes. Details are given of thirty-six cases in which the roentgen-ray reports are compared with the operative findings. In all of these the diagnosis was verified at the operation. Twenty-three photographs of diseased appendixes are shown, and eight colored drawings of appendixes after removal.

*Treatment of Pulmonary Tuberculosis in Children by Artificial Pneumothorax. E. Stolkind.—p. 18.

Aplastic Anemia.—Parkinson's patient, a boy aged 9 years, was first seen because of bruising all over the arms, shins, and back, and a rash resembling flea bites. For a month he had been bleeding at the mouth, the lips were painful and swollen, and the gums sore. For a fortnight he had had severe headache, and was noticed to be rather pale and breathless. The red cells numbered only 1,260,000; hemoglobin 20 per cent. The cause of the profound anemia was obscure. There was no reason to suspect scurvy, hemophilia, tuberculosis or syphilis. The Wassermann reaction in the blood was definitely negative. Lead poisoning was unlikely. There was no evidence of intestinal parasites. The blood showed marked leukopenia, due almost entirely to diminution in the number of the polymorphonuclears, the lymphocytes being in relative excess, but actually about normal in number. Ophthalmoscopic examination showed slight optic neuritis and numerus hemorrhages in both retinas. The anemia subsequently increased and the hemorrhages in the gums continued. The red cells went down to 624,000; the hemoglobin was 17 per cent. Then 300 c.c. of blood mixed with 30 c.c. of citrate solution were injected intravenously. The patient's color improved greatly during and after that procedure. A second transfusion was carried out ten days later. The child grew weaker and weaker and more drowsy, and had incontinence of urine and feces. Another transfusion was refused. The boy lay unconscious for a fortnight, and then slowly improved. At the present time he seems to have recovered completely.

Autoserum Treatment of Chorea.—Twenty-three cases are reported by Brown and others in which this treatment was employed. The first step consists in withdrawing about 50 c.c. of blood from the median basilic vein. The blood is received into three sterile test tubes. The test tubes are then put in the centrifuge for thirty to forty minutes. At the end of that time the serum is drawn up in a sterile pipet, emptied into a sterile test tube, and put in the incubator to keep at the proper temperature for injection. From 50 c.c. of blood from 20 to 25 c.c. of serum are obtained. This serum is injected intraspinally, care being taken not to cause pressure symptoms. The patients are kept in the hospital for one to two hours to watch for pressure or heart symptoms. Usually improvement follows in two or three days and has become stationary again by the end of the week, when they return to the hospital and another treatment is given. Following the injection there may be a mild disturbance, such as slight rise of temperature, a slight stiffness of the neck, or increase in pulse rate. These rapidly pass off. Nothing solid is given to eat for six to eight hours following the treatment. Of the twenty-three cases observed, 77 per cent. were cured, 19 per cent. improved, and one case unimproved, this patient having refused further treatment on account of a severe reaction. There has so far been no recurrence. Of the twenty-three cases, seventeen were of a mild degree and five were severe. In four instances the duration of the disease was over a year, while the remainder showed symptoms on an average of six and a half weeks' standing. The average number of injections given was three, but several were given one injection, while in one instance five were administered before a cure was effected. The average amount of serum employed was 17 c.c. Nineteen patients were cured in three weeks and four were cured within one week. All the severe cases required more than one injection.

Treatment of Pulmonary Tuberculosis in Children by Artificial Pneumothorax.—Stolkind is of the opinion that pneumothorax treatment should be applied, not only in adults, but also in children, in every case of advanced pulmonary tuberculosis; but not as a last resort, when it is too late.

Treatment of Bladder in Gunshot Injuries of Spinal Cord.—Intermittent catheterization and suprapubic cystotomy in the treatment of the paralyzed bladder after gunshot injuries of the spinal cord, Kidd says, should be discarded. In the hands of a careful worker mechanical expression of the bladder is likely to be the best method if it does not in the end diminish the chances of automatic action. This method is likely to ensure a more or less clean bladder, but it is questionable whether it will ensure an automatic bladder. Until this question is settled the method of the "tied-in" catheter is, on the whole, the best and most "fool-proof" method, and is likely to lead to the highest percentage of recoveries. After irrigating the urethra with a 33 per cent. aqueous solution of oxycyanid of mercury, the rubber catheter is passed into the bladder and is fixed with a safety pin. A piece of tape is tied to each end of the pin, is carried along the sides of the penis, and fixed there with adhesive straps. This strapping should be just tight enough to control the tapes, and yet not so tight as to cause edema of the prepuce. The tied-in catheter is left draining into a bottle all the time so that the bladder never becomes distended, a most important point. The bladder can be irrigated with oxycyanid of mercury solution (1 dram in 1 pint) twice a day. The catheter is removed every fourth day, the urethra irrigated and a fresh catheter inserted. By tying the catheter in place several objects are gained: 1. Time is not wasted by passing a catheter frequently. 2. The urethra is not damaged by the constant passing of a catheter. 3. The bladder muscle is not overstretched, so that automatic bladder can be established in a few weeks' time. 4. It is easy to carry out lavage, the urine remains clean, and pyelitis and stone are prevented.

Prompt Treatment of Chest Wounds.—Nixon emphasizes that all wounds of the parietes and thoracic contents should receive the surgical attention they require at the earliest possible moment. Hemorrhage must be arrested and every possible step taken to avert infection early. No fluid, whether blood, serum, or pus, must be allowed to collect in the chest. Early and frequent aspiration must be resorted to whether thoracotomy has been performed or not. Any fluid in the chest is dangerous from two points of view: (a) It is a nidus for sepsis. (b) It interferes with the expansion, not only of the injured, but also of the uninjured lung, setting up conditions favorable to the development and spread of bronchitis, bronchopneumonia, and lobar pneumonia. Foreign bodies, metal, clothing, and bone should be removed whenever possible. They are dangerous, not only from the point of view of immediate sepsis, but from that of subsequent interstitial fibrosis. Resection and open drainage as formerly practiced for empyema is an unsatisfactory operation, and is shown by experience in this war to be rarely necessary if the early treatment, according to modern methods, is not neglected.

Use of Methylene Blue in Infection of Orbit.—The prevailing micro-organism obtained by McIlroy by agar culture from nine cases of purulent discharge from the eye socket was found to be the *Staphylococcus aureus.* Methylene blue, although proved to be very active clinically in cases such as this one, was found to have comparatively little bactericidal action on the staphylococcus obtained from the discharge; 0.03 c.c. of a very dilute emulsion of the micro-organism, after even twenty-four hours' exposure to the drug, still yielded a number of colonies of growth after incubation.

Use of Calcium in Maniacal States.—Acting on deductions drawn from physiologic observations, Graves tested the effect of the exhibition of calcium lactate in persons suffering from various degrees of excitement. The action of the drug became evident at least during the twenty-four hours following its exhibition. The acute mental symptoms were alleviated without the production of the stupor so commonly observed following the use of "sedative" drugs. The circulatory response was equally interesting. Instead of the rapid, at times almost unaccountable pulse, with its flaccid artery and variable but always low systolic pressure, the pulse became slower, the artery normally constricted and the pulse-wave stronger, indicative of an improved action of the ventricular myocardium. The action of the drug was equally satisfactory in the distressing restlessness and excitement of agitated melancholia and confusional states as with the simple mania. Those cases in which influenza had become assigned as the principal cause have reacted well to the drug. These cases had resisted ordinary sedative treatment, but with this definite addition of calcium to the diet, a vicious circle seems to have been broken completely, and the patients made good progress toward recovery. Many of the other cases in which, owing to the duration of the character of the mental disorder, complete recovery can hardly be expected, have nevertheless shown amelioration of the more acute symptoms. Graves gives 10 grains, three times a day, with food, and when a response has been obtained drops the dosage to 5 grains. In one particularly distressing case of agitated melancholia, in addition to the doses by day, one or two doses were given at night. In one case of mania with diarrhea, not only was the restlessness and excitement allayed, but the number of stools fell from six to one. So far no untoward effects of any kind have been observed.

*Treatment of Sinuses Persisting After War Wounds. A. J. Turner.—p. 253.

Treatment of Sinuses Persisting After War Wounds.—The addition of a small amount of scarlet red powder Turner found was advantageous in the treatment of persistent sinuses. His paste consists of iodoform, ½ ounce; salicylic acid, ½ ounce; scarlet red powder, 25 grains; liquid petrolatum, about ½ ounce. If found a little too dry on rubbing into the tissues with dry gauze, a little additional petrolatum may be poured on the gauze so used. Turner has used this paste with good results in 110 cases. He found that it resulted in a saving of more than 44 per cent. of gauze, 18 per cent. of boric lint, 41 per cent. of plain lint, and 31 per cent. of cotton wool. There was also a saving of 49 per cent. of bandages, but this was partly due to sterilization and repeated use of all bandages, however soiled; so that none were wasted, except such as outpatients failed to bring back. One of the advantages of this antiseptic paste is the freedom from smell. Other advantages are the rapid fall of temperature in cases in which there has been fever, and the absolute comfort of the patient after one somewhat painful dressing.

Case of Intraperitoneal Abscess. G. K. Tambe.—p. 100.

Bacteriology of Blood and Treatment of Influenza in Calcutta.—Blood was taken by Brahmachari and Ghosh for culture in ninety cases of influenza. In ten cases the blood was taken from the heart under perfectly aseptic conditions within from half an hour to an hour after death. The cases were clinically divided under two heads: (1) mild cases in which no pneumonic symptoms were present, and (2) cases in which pneumonic symptoms were present and which were regarded as severe cases. The results of blood culture of these two types of cases was very characteristic. Thus, out of fourteen mild cases from which blood was taken for culture, only one showed the presence of streptococci in the blood, and this patient subsequently developed pneumonic symptoms and died. On the other hand, out of seventy-six severe cases, thirty-six showed the presence of streptococci or pneumococci in the blood. The blood cultures in positive cases generally showed the presence of streptococci or pneumococci. In two instances a pure culture of *Staphylococcus aureus* was obtained. Gram-negative, capsulated cocci, which formed no growth on agar or subculture, were obtained in two cases. In four cases bacilli somewhat resembling typhoid bacilli, but gram-positive, were obtained. A twenty-four hour culture of one of the strains of streptococci with hemolytic properties, obtained from the blood of one of the patients, was injected subcutaneously into one of the two guinea-pigs kept inside the same cage. The inoculated guinea-pig died after sixty hours. Smears were made of the spleen, the heart blood and the lungs. In every one of these the same kind of streptococcus was obtained as that with which the guinea-pig was inoculated. The second guinea-pig seems to have also been infected by contact (?) with the inoculated one. The second died three days after the death of the inoculated one, and the same strain of streptococcus was obtained in its organs as from those of the inoculated one.

*Clinical and Pathologic Notes on Fatal Case of Bilharzia Treated by Tartar Emetic. R. G. Archibald and A. Innes.—p. 54.
Rigor of Malarial Fever. M. D. O'Connell.—p. 55.

Fatal Case of Bilharzia Treated by Tartar Emetic.—The tartar emetic is blamed for the death of the patient whose case is reported by Archibald and Innes. The initial dose was ½ grain, followed after a day's interval with 1 grain, and after a similar interval by 1½ grains then by 2 grains, given every second day. After the injection of the first 2 grains there was a little vomiting and a slight degree of phlebitis at the site of the inoculation, which passed off in a day without ill effects. From this time on, each injection was followed by considerable cough with frothy expectoration, which, however, regularly subsided after fifteen minutes. After the seventh and eighth injections there was a slight rise of temperature. Subsequent injections were usually followed by elevation of temperature, never higher than 99.4 F. After a total quantity of 33 grains had been given the urine was examined and proved to contain blood but no bilharzial ova.

An epidemic of influenza occurred about this period, and three days after it first appeared in the ward occupied by the patient, he acquired the disease. He had a severe cough with respiratory embarrassment, a temperature of 105 F., and a pulse of 120. Although his temperature remained persistently high for the next two days, he did not appear to be losing ground. Suddenly, on the fourth day of the illness, he developed signs of collapse with sighing respiration and air hunger. The pulse became feeble and rapid, and, in spite of the usual heart stimulants, he died within an hour of the onset of the collapse. The findings obtained at necropsy convinced the authors that the pathologic changes in the organs were due to the action of tartar emetic, and were not sequels of bilharzia, influenza or a previous malarial infection.

*Treatment of General Paralysis of Insane by Introduction of Arsphenaminized Serum into Lateral Ventricle. H. Campbell and C. Ballance.—p. 608.
*Malaria and Trench Fever. G. Ward.—p. 609.

Treatment of General Paralysis of Insane.—Attention is directed by Campbell and Ballance to their first report (1914) on the treatment of general paralysis of the insane by the introduction of arsphenaminized serum into the lateral ventricle. They now suggest the same treatment for the arrest of optic atrophy. The optic nerve has a sheath derived from the dura mater, another derived from the arachnoid and another from the pia. The space underneath each of these sheaths can be injected separately. The injection beneath the arachnoid sheath passes into the substance of the optic nerve, and if made into the subpial space passes into the optic nerve and extends as far as the papilla, and this, it is suggested, should be the path which the curative serum should take so as to save the essential elements of the papilla and retina from destruction. Whether the injection should be made into the lateral ventricle or through the outer angle of the sphenoidal fissure into the subarachnoid space at the base of the brain remains to be determined.

Malaria and Trench Fever.—Ward believes that the close resemblance between malaria and trench fever does not seem to be generally appreciated. Rigor is usual in malaria, provided the patient is not taking quinin. It occurs, but is unusual, in trench fever. Quinin controls the temperature in malaria in most cases, i. e., it prevents more than one or two further rises to 103 or 104 F. This, of course, applies to temperate climate malaria. Quinin has no effect in trench fever. A rash is absent in malaria, but may be seen in trench fever. Leg pains are more frequent in trench fever, but may be of equal intensity in malaria. Some cases of malaria show a general pigmentation (often well seen in the lips), which increases with attacks and diminishes between them. This is not seen in trench fever. Finally, trench fever and malaria may be contracted *de novo* in England and the fact that a patient has suffered from one of them will not necessarily enable him to distinguish between a relapse of that one and the onset of the other.

Three Cases of Nephroma Embryonale. J. Saito.—p. 7.
*Oriental Constricted Liver (Schnur-Leber). F. Oshima.—p. 10.

Oriental Constricted Liver.—Oshima investigated sixteen cases of the so-called Oriental constricted liver (Schnurleber), and found that the course of the sulcus coincides with that of the vessel in the diaphragm. He is of the opinion that the fixation of the liver by the ligamentum suspensorium hepatis and the pressure of the Japanese woman's belt make the longitudinal sulcus of the liver immovable, and, moreover, the liver is pressed by the diaphragm from above and, because of the manner in which the Japanese sit, from below. As the liver tissue begins to show the effects of advanced age, there is a natural tendency to folding in the superior surface of the liver, corresponding to the sulcus sagittalis in the inferior surface. In addition to the above facts, if the congestion and pulsation of the vessels of the diaphragm exists, the surface of the liver should be pressed and molded by the vessel, such influences being the important factor in the occurrence of the sulcus (Oriental constricted liver). Therefore, the vessel of the diaphragm plays an important rôle in the development of this sulcus.

Fatty Degeneration of the Liver from Physiologic and Pathologic Standpoints. Gilbert and Surmont.—p. 213.
*Treatment of Malaria. G. Paisseau and J. Hutinel.—p. 216.
*Septicemia in Influenza. Cayrel.—p. 221.

Treatment of Malaria.—Paisseau and Hutinel present arguments from their own experience to prove that the combination of arsphenamin with quinin is much more effectual than the latter alone in treating malaria. They gave an intramuscular injection of 1.20 gm. of quinin at the beginning or during the malarial attack, followed within twenty-four hours—preferably from six to twelve—with an intravenous injection of 0.15 gm. arsphenamin. This is repeated every week, with mild tertian, increasing the dose of the arsphenamin to 0.30 gm. With malignant tertian, they give two injections of the quinin daily until the temperature is normal. Then 0.15 gm. arsphenamin is injected, and after this 2 gm. of quinin by the mouth until the temperature has been normal for two days. The two drugs are then kept up once a week for two months and, during a third month, once a fortnight. Iron and epinephrin are useful adjuvants.

Septicemia in Influenza.—Cayrel cites from various writers their conflicting views on this subject. The variability of the microbian flora and the date when the cultures are made from the blood seem to offer the only explanation of the divergent findings.

War Neurasthenia. M. Page and E. Gauckler.—p. 134.
*Radium Emanations for Treatment of Cancer. F. Jeunet.—p. 136.

Aseptic Operations on Stomach and Intestine.—Gudin gives sixteen illustrations of a crusher clamp with thumb screw for gastro-intestinal operations which, he says, absolutely prevents escape of the contents, coaptates the mucosa, and does not crush the tissues enough to impair their vitality.

Needles Coated with Radium Emanations in Treatment of Cancer.—Jeunet is convinced that applying radium emanations on needles is the method *par excellence* for radium treatment of cancer. As many needles can be used as desired, and the practitioner can thus have it in his power to undertake a serious offensive against the malignant disease, with the minimum of discomfort for the patient, while the emanations are carried into the depths of the tumor, just where they are most needed. The needles lose their potency in about four days, but they can be recharged. This requires merely an accessible industrial source for production of the emanations. He remarks that the works of Danne, in particular, have aided in rendering this feasible. The needles are much like ordinary sewing needles, the surface is covered with the emanation like a coating of mist. As the emanation is easily wiped off, it is coated outside with collodion or celluloid. The emanation content of each needle is tested with the gold-leaf electroscope. With these needles the practitioner, he says, can induce the complete retrogression of certain neoplasms, render others operable, ward off or abort recurrence, abolish pain, deodorize, and otherwise "cure morally" the inoperable and incurable cancers. Jeunet does not give further specific directions or mention any concrete experiences.

*Uremia with Retention of Urine. F. Legueu.—p. 141.
*Traumatic Headache. R. Benon.—p. 142.
*Chronic Nephritis and the Previous Condition. M. Nathan.—p. 143.

Uremia with Retention of Urine.—Legueu refers to the uremia with prostatic or other retention of urine, readily curable by evacuation of the urine. Ambard's coefficient has little or no significance in these cases, as the kidneys may be intact. Catheterization several times a day will cause the prompt subsidence of azotemia from this cause. The thirst, the digestive disturbance, the polyuria, the susceptibility to infection, are explained by the distention of the bladder, but they may occur even with incomplete retention, and the uremia may increase to a fatal termination unless the poisoning from the incompletely voided bladder is recognized in time. The diet and drugs are far less important than systematic voiding of the urine. Otherwise the pressure on the ureter mouths causes disturbance which may reach to the kidneys and modify their secretory functioning. With azotemia of less than 1 gm., the Ambard constant may prove instructive; with over 1 gm. the degree of uremia is the main feature of the case. This must be supervised and brought down to 1 gm. before any operation, even cystostomy, is attempted for the prostatic lesion responsible for the retention. With uremia up to 2 gm., any operation of the kind would be inevitably fatal, even under local anesthesia, while the subsidence of the uremia under regular voiding of the bladder prepares the patient for the operation on the prostate.

Traumatic Cephalalgia.—Benon describes the primary, immediate and essential post-traumatic cephalalgia which is sometimes encountered after war wounds or aerial shock. It calls for tranquil surroundings and out of door life. Lumbar puncture does not benefit and may even aggravate the condition.

Chronic Nephritis.—Nathan cites some instances to illustrate the way in which Bright's disease searches out and aggravates the preexisting weak points in the body. *Chacun fait son brightisme avec son passé et son hérédité.* The localization of the symptoms at first depends essentially on the preexisting state; apparently extinct lesions are liable to flare up under its influence and mask the causal kidney disease. Treatment should be directed to the kidneys to attenuate the superposed nephritic phenomena. This is the only way to study these complex cases which form the daily bread of pathology. By treatment on this basis, the masked "brightism" can perhaps be kept under control, with long survival and a fairly active life.

*Cesarean Section Versus Instrumental Dilation. Carlini.—p. 49.
Fibromyxoma of Round Ligament. C. Walther.—p. 60.

Instrumental Dilation.—Carlini writes from Bossi's clinic to extol the benefits of instrumental dilation in appropriate cases, describing twelve cases. He criticizes some recent reports on vaginal cesarean section, declaring that the cases in which it was applied would have fared better with instrumental dilation. Any practitioner can apply the latter, he reiterates.

Deutsche medizinische Wochenschrift, Berlin

Jan. 9, 1919, **45**, No. 2

Study of Causes and Conditioning Factors. (Ursachenforschung, Ursachenbegriff und Bedingungslehre.) O. Lubarsch.—p. 33. Commenced in No. 1, p. 1.
*Nitrogen or Air in Artificial Pneumothorax. K. Henius.—p. 36.

Treatment of Gonorrhea in the Female. Weinberg.—p. 42.
*Butter Gruel in Infant Feeding. K. Ochsenius.—p. 42.
*Poisoning from Treatment of Varicose Veins. F. Hammer.—p. 45.

Absorption of Air and of Nitrogen with Artificial Pneumothorax.—Henius reports research on a dog injected in turn with air and with nitrogen to induce pneumothorax. The tabulated findings show that air is not absorbed any more rapidly than nitrogen, and hence that air can successfully compete with nitrogen for production of artificial pneumothorax in man.

Latent Infection.—Loeser expatiates on the lessons learned during the war in regard to the danger from latent infection. Aside from the gonococcus, latent infection in the genital tract of women may be of dire importance for the course of the puerperium. The saprophytes acquire virulence under the traumatic conditions of parturition. The constitution and the latent infection anywhere in the body form a vicious circle when the vitality gets depressed from any cause. The metabolic products from latent infection may also possibly be a factor in arteriosclerotic processes and in the growing old of the tissues.

Pseudomembranous Obstruction of Air Passages in Influenza.—Meyer has encountered fifteen cases of this kind; the age ranged from 1 to 40 years. All these patients had fever up to 40.4 C. (106 F.). Notwithstanding the diphtheria-like symptoms, there was no deposit to be seen in the throat or tonsils, but in six of the eight fatal cases the larynx, trachea and bronchi were scattered with patches of pseudomembranes firmly attached to the mucosa. The seven patients who recovered expectorated for a long time a thick, fibrin-rich yellow sputum. Diphtheria antitoxin was given in every case, as it was impossible to exclude diphtheria positively, and he ascribes the recovery mainly to this although it had no specific action. An emergency tracheotomy was done in six cases, but the progressive pseudomembrane production continued unchecked or the heart gave out. Intubation proved successful in two children.

Poliomyelitis in the Army.—Stern reports that five soldiers with poliomyelitis reached his hospital on the eastern front, all within a short period, and all from the Ukraine front. The paralysis retrogressed more or less completely in each case, although in one there was evidently superposed hysteria. Nothing was known of an epidemic among children, and there was nothing to indicate syphilis in any case, but in two instances, attention had been called to the great mortality among poultry at the time.

Spinal Analgesia.—Frank emphasizes that the anesthetic should be allowed to flow into the spinal cavity almost spontaneously. The term "injection" is in itself misleading, although the syringe has to be used. The whole should be done extremely slowly and gently, the patient breathing deep

urine was examined an
bilharzial ova.

t **Feeding.**—Ochsenius extols the fine
gruel made with 7 gm. butter; 7 gm.
ugar in 100 gm. of the vehicle. The butter
and stirred with a wooden spoon until it foams and
the odor of fat acid disappears, which occurs in from three to five minutes. Then the fine wheat flour is added and blended with the melted butter and cooked on an asbestos plate until the whole is thin and brownish (about four or five minutes). Then the warm water and sugar are added, and the whole boiled up and forced through a hair sieve; then the boiled and cooled milk added. The proportions between the butter and the flour must always be the same, but the other ingredients can be modified. This is the Czerny-Kleinschmidt *Buttermehlsuppe* and the experiences published with it to date have been very satisfactory. This has been confirmed by Ochsenius' experience in seventy-six cases in the course of the last half year, including his own infant. The rule is to give not more than 80 gm. at a feeding. He was impressed with the transformation of the nervous, restless, crying children into a phase of quiet, smiling content, on this food. He never witnessed such a rapid change under other methods of feeding. It proved particularly useful for infants with incipient or established intolerance for cow's milk; some gained up to 300 gm. a week.

Mercurial Poisoning from Local Treatment of Varicose Veins.—Hammer injected 1 c.c. of a 1 per cent. solution of mercuric chlorid, fractioned, in the much enlarged, ulcerated vein on the leg. The patient was a robust woman of 36 who had two living children out of five pregnancies. Vomiting and diarrhea followed in an hour and a half, with anuria, edema, and fatal collapse the twelfth day. The injections were made strictly according to Linser's technic. The products of putrefaction in the ulcer probably cooperated in the violent reaction. The drug was injected hoping to induce immediate coagulation in the vein, to obstruct it, but this evidently did not occur.

Are the Alcoholic Degenerates? H. Preisig and K. Amadian.—p. 147. In French.
*The Biochemistry of the Brain. G. Pighini.—p. 177. In Italian.

The Mechanism of Hemiplegia.—Eggers presents what he calls a new conception of hemiplegia. He declares that the classic conception of the rôle of the pyramidal tracts does not harmonize with what is observed in hemiplegia. The subject in time regains the use of his leg for walking and the movements connected therewith, while the volitional movements persist as defective still as they are in the arm. The five examples of hemiplegia under prolonged control, which he describes, apparently demonstrate that the degeneration of the pyramidal tract paralyzes *only* centripetal contraction and leaves centrifugal contraction practically intact. In other words, it paralyzes only the apparatus for volitional movement.

Varieties of the Babinski Reflex.—Bing's study of the Babinski reflex in the purely cerebral and the purely spinal cases of spastic paralysis, with their transitional forms, is based on 246 cases. Among other points to which he calls attention is the absence of the Babinski reflex in cases of amyotrophic lateral sclerosis; it was absent in all of his six cases in this category. In six cases of *état lacunaire* of the brain, the Babinski was positive in five, but the reflexogenous zone was restricted to the sole.

The Biochemistry of the Brain.—The articles in the *Archiv* are all in German except when otherwise specified. Pighini's research on this subject is merely summarized here from a course of five graduate lectures recently held at Turin.

*Shoulder Presentations in Different Countries. A. Ippolito.—p. 137.

March 9, 1919, 40, No. 20

Symptomatology with Projectile in Chest. G. Pisanò.—p. 155.

Frequency of Shoulder Presentation in Different Countries. Ippolito cites statistics from six different countries which show that the proportion of shoulder presentation ranges from 0.35 per cent. (America) and 0.36 (England) to 0.58 (Germany) and 0.66 (France) to 0.71 (Austria). Italy, on the other hand, has an average of 1.40 per cent. shoulder presentations, according to the figures of Pasquali and Corradi, but Ippolito in 10,000 deliveries in twenty years of practice in Sicily has encountered shoulder presentation only in 0.12 per cent. He theorizes to explain this great difference, saying that a tendency to shoulder presentation seems to be an ethnic-anthropologic phenomenon. Comparing the average height of the different races shows that shoulder presentation becomes less frequent the taller the women; least in Anglo-Saxons, it is most frequent in the Slavic races of Austria. At the same time, the distance between the lower margin of the xiphoid appendix and the upper margin of the pubic symphysis seems to be remarkably constant in women, irrespective of their height, Nature striving to maintain an ample vertical diameter in the abdominal ovoid. Sicilian women are short, but the shortness is in the legs; the length of the trunk and the distance between the xiphoid appendix and the pubis are rather above the average than below. He insists, therefore, that the xiphopubic measurement is one of the most important obstetric measurements for oversight of conditions in pregnancy and delivery. He ascribes to the clothing, the absence of corsets and of factory work, the physiologic development of the genital sphere in the women of Sicily.

*Ether and Chloroform and the Leukocyte Count. C. Oliva.—p. 96.
Secondary Hemorrhage with Gas Gangrene. P. Amorosi.—p. 108.

Albumin in the Sputum.—Durand examined the sputum for albumin in 120 cases of pulmonary tuberculosis and in large numbers of cases of pneumonia, simple catarrh, etc. The findings corroborate the assumption that albumin in the sputum has no diagnostic significance, but that it is important for the prognosis. The quantitative variations in the albumin content are proportional to the activity, the extent and the depth of the pulmonary lesion.

Ascariosis.—Rotolo reports that a previously healthy woman of 26 developed a condition diagnosed as influenza just before delivery of her first child. The puerperium was apparently normal but the thirteenth day came a dull pain in the right hypochondrium, and the eighteenth day a chill and fever, subsiding by the next day. That same evening a violent prolonged chill and fever to 104 F. were accompanied by intense exaggeration of the continuous pain in the right hypochondrium. By exclusion and the history that an ascaris had been passed a few days before, Rotolo was inclined to incriminate helminths, and under santonin a tangled wad of six long ascarides was passed, with three others later, and all local and general disturbances ceased at once and permanently.

Projectile in Heart.—The preceding instalment of Scalone's article was mentioned in these columns, April 26, p. 1620. His conclusions from extensive study of the immediate and remote effects of war wounds of the heart are to the effect that a projectile loose in the heart cavity should always be removed on account of the danger of its being swept along. When the projectile is embedded in the myocardium, its removal will not undo the injury already inflicted on the myocardium, and may materially aggravate it. If it is not causing grave disturbance of the intrinsic innervation of the heart, he thinks it is wiser to leave it untouched. In every case the advantages and drawbacks of an operation should be carefully balanced before deciding; the question is not one of technic but of physiopathology.

The Leukocytes with Chloroform and Ether.—Oliva's experiments on rabbits confirmed the general assumption that ether does not induce leukocytosis, like chloroform, and does not seem to display a toxic action on the liver and other tissues.

*Objective Sign of Cardiac Neurosis. C. Minerbi.—p. 87.

Objective Sign of Neurosis of the Heart.—Minerbi has the subject lie supine and he then lifts the legs nearly vertical. As he lets go of the legs, he tells the subject to lower them himself, very slowly and gradually, not to let them fall loose. The outline of the heart has been previously determined and it is determined anew at once after this maneuver. In physiologic conditions, the upper outline of the heart will be found at least 2 or 3 cm. below what it was before. There is evidently a symmetrical retraction of the auricles, but the rest of the outline is found unmodified. In cases of a neurosis of the heart, however, the outline will be found incredibly shrunken all around—a universal retraction toward the center of the heart.

Mongoloid Idiocy. E. Meirelles.—p. 738.
Hemiplegias. F. Esposel.—p. 750.

Hemostatic Serum.—Magalhães discusses the use in obstetrics of the hemostatic serum made at the Instituto de Butantan by O. Veiga. It is merely the coagulating elements isolated from normal horse serum, by diluting to one half and treating with a saturated solution of ammonium sulphate. In a threatening case of internal hemorrhage from tubal abortion, Magalhães injected by the vein 5 c.c. of this hemostatic serum, while efforts were made to reanimate the woman. In half an hour the condition was entirely satisfactory; the blood evidently clotted soon. In another case, cesarean section required for placenta praevia had been preceded by intravenous injection of 5 c.c. of this hemostatic, and he was impressed with the advantages from it.

*The Pirquet Skin Tuberculin Reacti[illegible]
*Diphtheria at Lisbon. N. Bettencourt.—p. 111.

Experimental Syphilis in the Rabbit.—Pulido Valente remarks that his findings did not accord altogether with those that have been reported by others, as he explains in detail. See second abstract below.

Helminths in Lisbon Children.—Paes states that no systematic investigation of intestinal worms has ever before been made in Portugal in either children or adults. She had the stools of 503 children examined, and helminths were found in 54.1 per cent. The helminths represented were trichocephalus (44.7 per cent.); ascaris (18.1 per cent.); dwarf tapeworm (6.5 per cent.); and the oxyuris in 2.2 per cent. In some of the children there was more than one species. The largest proportion with helminthiasis were between 2 and 4 years old. After 9, the proportion rapidly declined.

Pathogenesis of General Paralysis.—Pulido Valente's three articles are accompanied by six fine colored plates and extensive bibliography. His research has confirmed the early penetration of the pale spirochetes into the meninges. He has found them in the cerebrospinal fluid as early as the second month after infection. The pale spirochete that induces paralysis seems to have become modified and to have acquired especially injurious properties in respect to nerve tissue. The difference in aggressivity for the nerve tissue displayed by different generations of the same strain of spirochetes was strikingly demonstrated in his experimental research. An interesting problem is to determine whether the pale spirochete inducing paretic dementia has become resistant to our therapeutic measures. Ehrlich was inclined to accept this as the cause of the failure of specific treatment in paretic dementia.

Rabies at Lisbon.—In 1913 and 1914, 3,477 persons were given antirabic treatment at the institute; nine persons died during treatment or in less than two weeks afterward, and two died later. The number treated has constantly increased but the mortality has dropped from 1.75 per cent. in 1895 to zero in five recent years; it was 0.06 and 0.10 in the two years in question. Cats, cattle, asses, monkeys and wolves had been incriminated as well as 1,634 dogs and forty-two human bites. One child of 7 developed rabies nine months after the antirabic treatment.

Skin Tuberculin Reaction.—Lopes concludes from application of the Pirquet test to 312 children and 218 adults that it may be regarded as almost infallible for young children. The reliability decreases in inverse proportion to the age. In the much debilitated, the absence of the reaction always proves an unfavorable sign.

Doses for Children.—Sierra comments on the absurdity of any formula to be applied to all children, indiscriminately, by age alone. He advises fractioning the dose and increasing it until the desired result is attained, watching out closely for individual intolerance which may compel the complete suspension of the drug. For infants under a year old, he begins with the fifth of the adult dose, fractioning it through twenty-four hours. From 1 to 4 years old, the fourth of the adult dose; from 3 to 6, a third, and from 6 to 15, a half.

Skiascopy.—In this second article on the mechanism of skiascopy, Márquez presents experimental data to sustain his assumptions, with six additional charts.

Diagnosis of Incipient Tuberculosis.—Hyvert's article is accompanied with five fine roentgen plates, nearly 11 by 15 inches in size, besides a number of smaller illustrations, and he emphasizes the instructive points in each for the diagnosis of incipient tuberculosis.

Danger of Apparent Death During Epidemics.—Lecha-Marzo's research on means to distinguish between real and apparent death has been described in these columns at different times, as on page 1010, Sept. 29, 1918. He here reiterates that in countless healthy persons and in 1079 persons of both sexes and in many hundreds of cases of diseases of the eye (which he lists separately) the reaction of the tears during life was invariably alkaline. Tested after death, by slipping a scrap of litmus paper under the eyelid, the reaction equally invariably veered to acid. The change was sometimes evident in half an hour, and only exceptionally took up to several hours.

Roentgen Treatment of Epithelioma of the Penis.—Ratera applied 28 roentgen units, June 18, 1915, and 21 units, June 19, treating the lesion afterward with a zinc oxid salve. By October the cancer had entirely disappeared, and there has been no return during the three and a half years to date.

Renal Tuberculosis. M. Mendez S.—p. 241.
Glaucoma. C. M. Pava.—p. 245.

Drugs Contraindicated in Pregnancy.—Muñoz asserts that he views with horror the administration of potassium iodid to pregnant women, as he has seen it induce abortion, kill the fetus in the later months, and even sacrifice the nursling, when the drug had been used for local application to the breast. He reports a case of each of these contingencies. Iodin seems to act like a stimulant; it exaggerates the menstrual flow and may induce actual hemorrhage. Both iodin and potassium iodid have been extolled by Russian physicians as effectual in typhus. Muñoz' experience confirms the benefit from potassium iodid in treatment of inveterate amenorrhea in robust women; also by hypodermic injection in treatment of the neuralgias of diabetics, instead of morphin. He warns further that morphin should not be given when there is nephritis with albuminuria.

Action of Epinephrin on Muscular Fatigue of Frogs and Toads. J. Guglielmetti.—p. 774.
*Treatment of Obesity. L. O. Romero.—p. 796.
Record of Oscillometer Pulse Findings. F. L. Soler.—p. 813.

Treatment of Obesity.—Romero remarks that charlatans' advertisements, promising "to reduce the weight by 30 pounds" if their medicines are taken, have educated the public to believe that it is a simple and prompt matter to cure obesity. The physician has to start from the foundation and instruct and train the patient to be the guardian of his own health. In order to reestablish the functional balance, indispensable for the cure, extremely minute and detailed examinations and supervision of the metabolism, etc., are necessary. Romero's experience has taught him that the obstacles for success do not come from the patient himself so much as from the prejudices of those around. He outlines a ten months' course of treatment. The first month he devotes to resting the digestive and muscular apparatus, beginning with two days allowing only water, and two purges with a twenty-four hour interval. A mixed diet is then allowed, with green vegetables, cooked without condiments, and in small amounts. No drinking with meals. Thorough mastication is enforced, and Romero takes some of the first meals with the patient to train in careful mastication. All fatigue is avoided, even walking to the office. Every day the patient is weighed, always at the same hour, after stool, fasting and unclothed. The general health improves and up to 10 pounds may be lost the first month.

Psychotherapy is important to counteract the prejudices and fears of friends, and to educate the weak will of the obese. The second month, slow gradual myotherapy is begun, with gymnastic exercises under the physician's supervision. By the third month the benefit has been so pronounced, usually, that the patient is full of enthusiasm, but still the muscular exercise must be promoted with skill and tact; persuasion and energy are necessary. If the physician fails to make the muscular exercise a pleasure and have it done with conviction, the course of treatment will fail. Careful breathing exercises are important likewise, and air baths and sun baths can be begun as also organotherapy, at this time, if it is indicated. In the fourth month he suppresses meat and applies massage to the main deposits of fat, with hot or cold douches, a cold shower after a rapid walk or sun bath. The fifth month he tries the effect of suppression of salt for a time, giving nothing but fruits and whole bread for a few days. In the three following months all this treatment by the natural agents, myotherapy and elimination of waste, is kept up, and meat is allowed on certain days to make up for the muscular play, but very little salt and not much butter are permitted. During the last two months the effect on the weight of different articles of food is studied, and the patient is impressed anew that the final outcome depends on the functional balance, which is under the control of his strong will power that has been gradually developed. Romero insists that obesity in the young and in the aged should be combated on the same plan. In other affections, the patient is usually a passive element in the treatment, but in treatment of obesity the patient must work out his own salvation, and the physician's task is to get him to do this. Mental indecision is one of the most prominent features of the syndrome of obesity. Romero gives no details of special cases.

Jalap in Therapeutics. S. Velazquez de Castro.—p. 198.

Tuberculosis of Seminal Tract.—Sacco reports that he had 33 per cent. of failures in his cases of genital tuberculosis in men treated by simple castration. On the other hand, 100 per cent. permanent cures were realized by systematic orchivasovesiculectomy as he describes in detail. His analysis of the literature on tuberculosis of the seminal tract shows that widely diverging views are held by different surgeons. None of them have reported 100 per cent. cured as he realized in those of his eight cases of genital tuberculosis treated by this "ideal castration."

Infectious Jaundice. M. Vila.—p. 132.

Balmis and His Work.—This year is the centennial of the death of this early missionary of vaccination, sent out by Spain to vaccinate the New World.

Cardiothyroid Disease.—Del Cañizo discusses the severe functional disturbance in the heart action liable to be entailed by excessive thyroid functioning with or without actual exophthalmic goiter. All the goiter-heart cases fall into two groups (1) those with extremely toxic hyperthyroidism entailing severe functional derangement of the heart action, and (2) those with chronic goiter but the symptoms of toxic action from the thyroid are mild, and yet the heart is organically impaired. He cites examples of each of these two types and remarks that the difference between them is mainly that of time. Acutely fatal exophthalmic goiter, as in a case he describes in a previously healthy young woman after a severe emotional shock, represents the extreme of Type 1. In time, however, they all settle down into the chronic form of Type 2.

Rupture of the Fundus of the Uterus. P. G. Rinsema.—p. 458.

Fermentation in the Urine with Pyelitis.—Peters was able to find on record only four cases like the one he recently encountered himself in which the urine was thick and ropy and showed signs of fermentation. His patient was a pregnant young woman with pyelitis and intermittent fever. This phenomenon of jellification and fermentation of the urine seems to be the work of a special variety of colon bacilli, the *Bacterium coli mobile capsulatum.* It has been called the *Bacterium glischrogenum* by others. In the total five cases it was found in pure culture in the urine. The pyelitis in his case was evidently a pregnancy pyelitis; it subsided after the normal delivery, and the urine returned to normal after the bladder had been disinfected.

Index of Nutritional Condition of Schoolchildren.—Van der Loo remarks that as children grow taller they increase more proportionately in weight than in length, so that the weight divided by the square of the length of the body gives a fairly good index for comparison of conditions in different children or in the same child at different times.

*Congenital Defective Osteogenesis. A. Johannessen and T. Eiken.—p. 257. Conc'n.

Defective Osteogenesis—Johannessen and Eiken here describe research on congenital imperfect osteogenesis, and on its connection with genuine osteomalacia, adding considerable bibliography. They had occasion to study a typical case from the first day after birth to the necropsy at thirteen months. The anomaly seems to be due to inability to utilize calcium, rather than to a lack of calcium.

*Syphilis and Neurorecurrence in Auditory Nerve and Labyrinth. C. Jacobsen.—p. 471.
*Fermentation Dyspepsia in Children. C. Thorsen.—p. 481.

Neurorecurrence of Syphilis in the Auditory Nerve or Labyrinth.—Jacobsen analyzes four cases in which sudden deafness, subjective noises in the ear, or vertigo with vomiting were the warning that the syphilis had invaded the organ of hearing or that the drugs used had induced a toxic action. Analysis of these and similar cases on record seems to show that part of the neurorecurrences are due to a Herxheimer reaction to arsphenamin. This reaction congestion in a nerve confined in a narrow passage through bone injures the nerve and may cause permanent trouble. But the majority of cases of disturbances in the auditory nerve are the result of actual damage from the syphilis, combined with or possibly secondary to a syphilitic meningitis. There may possibly be also a small contingent of cases in which the nerve is suffering from a direct toxic action from the arsphenamin. Even in persons with normal ears, special care should be exercised in giving arsphenamin; during the exanthem stage or a little before this, it is wiser to give the arsphenamin only in combination with mercury. With actual syphilis and neurorecurrence in the auditóry nerve, arsphenamin must be pushed but it is indispensable to give mercury with it if the trouble is recent. Lund's experience with nine cases of neurorecurrence in the auditory nerve confirms anew the absolute necessity, he declares, for giving mercury for a time before beginning with the arsphenamin. In three of his cases, with infection dating from six to twelve weeks before, there had been some slight signs of vestibular neuritis. Under the associated arsphenamin and mercury treatment this became very much worse, to complete vestibular paralysis in one case. There had been very little, if any, mercury given before this. A preliminary course of mercury might have warded off injury.

Intestinal Fermentation Dyspepsia.—Thorsen remarks that while intestinal fermentation dyspepsia in infants is now a well recognized and manageable clinical picture, in older children it often is misinterpreted. Examination of the watery and frequent stools will reveal the carbohydrate dyspepsia, and the cure under treatment on this basis will confirm the diagnosis. The small intestine is incapable of digesting carbohydrates properly. The products of the fermentation irritate the mucosa of the bowel. Modifying the diet corrects conditions but this has to be long kept up, and relapses are frequent, although final restoration of normal conditions is the rule. He gives no directions as to treatment, but describes the clinical picture. A boy of 12 or 13 may have to go to stool four or five times during school in the morning, or the stools may follow the meals, the child being scarcely able to wait for the close of the meal. The child is not disturbed during the night, but the sleep is generally restless, and several thin passages and much flatus are the rule in the morning. There is also a tendency to tympanism but the appetite keeps good and the child usually seems well nourished, but inclined to lassitude to such an extent that older children find it difficult to keep up with with their class in school. Younger children are cross and cry readily, and at all ages the children find it difficult to hold their urine long, and they may occasionally wet the bed. The mother of one such child knew always by the child's lassitude and irritability when an attack of diarrhea was impending.

THE VICTORY MEETING

ATLANTIC CITY SESSION

AMERICAN MEDICAL ASSOCIATION, SEVENTIETH ANNUAL SESSION, ATLANTIC CITY, JUNE 9-13, 1919

OFFICIAL CALL

TO THE OFFICERS, FELLOWS AND MEMBERS OF THE AMERICAN MEDICAL ASSOCIATION

The seventieth annual session of the American Medical Association will be held in Atlantic City, N. J., June 9-13, 1919.

The House of Delegates will convene at 10 a. m., Monday, June 9. In the House the representation of the various constituent associations for 1919 is as follows:

Alabama	3	New Hampshire	1
Arizona	1	New Jersey	3
Arkansas	2	New Mexico	1
California	3	New York	11
Colorado	2	North Carolina	2
Connecticut	2	North Dakota	1
Delaware	1	Ohio	6
District of Columbia	1	Oklahoma	2
Florida	1	Oregon	1
Georgia	2	Pennsylvania	9
Idaho	1	Rhode Island	1
Illinois	8	South Carolina	1
Indiana	3	South Dakota	1
Iowa	3	Tennessee	2
Kansas	3	Texas	5
Kentucky	3	Utah	1
Louisiana	2	Vermont	1
Maine	1	Virginia	3
Maryland	2	Washington	2
Massachusetts	5	West Virginia	2
Michigan	4	Wisconsin	3
Minnesota	2	Wyoming	1
Mississippi	1	Canal Zone	1
Missouri	5	Hawaii	1
Montana	1	Philippine Islands	1
Nebraska	2	Porto Rico	1
Nevada	1		

The fifteen scientific sections of the American Medical Association, the Medical Department of the Army, the Medical Corps of the Navy and the Public Health Service are entitled to one delegate each.

The general meeting, which constitutes the opening exercises of the Scientific Assembly of the Association, will be held at 8:30 p. m., Tuesday, June 10. The various sections of the Scientic Assembly will meet Wednesday, June 11. at 9 a. m. and at 2 p. m., and subsequently, according to their respective programs.

The Registration Department will be open from 8:30 a. m. until 5:30 p. m., on Monday, Tuesday, Wednesday and Thursday, June 9, 10, 11 and 12, and from 8:30 a. m. to 12 noon, on Friday, June 13.

Arthur Dean Bevan, President.
Hubert Work, Speaker, House of Delegates.
Alexander R. Craig, Secretary.

MEMBERS OF THE HOUSE OF DELEGATES

A Preliminary Roster of the Legislative Body of the American Medical Association

The list of members of the House of Delegates for the session is incomplete, as a number of the state associations are yet to hold their meetings at which delegates will be elected. The following is a list of the holdover delegates and of the newly elected members who have reported to The Journal in time to be included:

STATE DELEGATES

ALABAMA

S. W. Welch, Montgomery.
S. G. Gay, Selma.

ARIZONA

R. G. Stroud, Gleason.

ARKANSAS

C. P. Meriwether, Little Rock.

CALIFORNIA

George H. Kress, Los Angeles.
V. G. Vecki, San Francisco.

CANAL ZONE

COLORADO

L. H. McKinnie, Colorado Springs
J. N. Hall, Denver.

CONNECTICUT

J. E. Lane, New Haven.

DELAWARE

P. W. Tomlinson, Wilmington.

DISTRICT OF COLUMBIA

G. Wythe Cook, Washington.

FLORIDA

John S. Helms, Tampa.

GEORGIA

S. R. Roberts, Atlanta.
H. H. Martin, Savannah.

HAWAII

A. N. Sinclair, Honolulu.

IDAHO

ILLINOIS

R. J. Coultas, Mattoon.
T. D. Doan, Scottville.
E. B. Coolley, Danville.
C. E. Humiston, Chicago.
L. Hektoen, Chicago.
C. W. Leigh, Chicago.

INDIANA

Charles Stoltz, South Bend.
A. E. Bulson, Jr., Fort Wayne.
Joseph R. Eastman, Indianapolis.

IOWA

John C. Rockafellow, Des Moines.
M. N. Voldeng, Woodward.

ISTHMIAN CANAL ZONE

R. U. Runyan, Panama.

KANSAS

Charles S. Huffman, Topeka.

KENTUCKY

Carl L. Wheeler, Lexington.
W. W. Richmond, Clinton.

LOUISIANA

MAINE

MARYLAND

Randolph Winslow, Baltimore.
Thomas S. Cullen, Baltimore.

MASSACHUSETTS

J. B. Blake, Boston.
H. G. Stetson, Greenfield.
L. F. Woodward, Worcester.
F. B. Lund, Boston.
E. F. Cody, New Bedford.

MICHIGAN

A. W. Hornbogen, Marquette.
F. C. Warnshuis, Grand Rapids.
Guy Connor, Detroit.
J. G. Brook, Grandville.

MINNESOTA

George D. Head, Minneapolis.
W. H. Magie, Duluth.

MISSISSIPPI

Willis Walley, Jackson.

MISSOURI

W. J. Ferguson, Sedalia.
A R. McComas, Sturgeon.
Franklin E. Murphy, Kansas City.

MONTANA

Rudolph Horsky, Helena.

NEBRASKA

Joseph M. Aikin, Omaha.

NEVADA

William Z. Dahl, Reno.

NEW HAMPSHIRE

Robert J. Graves, Concord.

NEW JERSEY

Luther M. Halsey, Williamstown.
Edward Guion, Atlantic City.
George H. McFadden, Paterson.

NEW MEXICO

H. A. Miller, Clovis.

NEW YORK

James W. Fleming, Brooklyn.
Dwight H. Murray, Syracuse.
Frederic E. Sondern, New York.
George W. Kosmak, New York.
Arthur J. Bedell, Albany.

NORTH CAROLINA

H. A. Royster, Raleigh.
C. P. Ambler, Asheville.

NORTH DAKOTA

Charles MacLachlan, New Rockford.

OHIO

OKLAHOMA

LeRoy Long, Oklahoma City.
Charles R. Hume, Anadarko.

OREGON

PENNSYLVANIA

W. F. Bacon, York.
G. R. S. Corson, Pottsville.
H. B. Gibby, Wilkes-Barre.
George G. Harman, Huntingdon
Wilmer Krusen, Philadelphia.
Edward B. Heckel, Pittsburgh.
John D. McLean, Philadelphia.
David N. Dennis, Erie.
John M. Baldy, Philadelphia.

PHILIPPINE ISLANDS

PORTO RICO

Jorge del Toro, Santurce.

RHODE ISLAND

F. T. Rogers, Providence.

SOUTH CAROLINA

Edgar A. Hines, Seneca.

SOUTH DAKOTA

TENNESSEE

E. T. Newell, Chattanooga.

TEXAS

I. C. Chase, Fort Worth.
M. L. Graves, Galveston.

UTAH

Joseph R. Morrell, Ogden.

VERMONT

F. T. Ridder, Woodstock.

VIRGINIA

W. E. Anderson, Farmville.
Southgate Leigh, Norfolk.

WASHINGTON

H. H. McCarthey, Spokane.
D. E. McGillivray, Pt. Angeles.

WEST VIRGINIA

Frank LeMoyne Hupp, Wheeling
Chester R. Ogden, Clarksburg.

WISCONSIN

C. H. Lemon, Milwaukee.
Horace M. Brown, Milwaukee.
Rock Sleyster, Wauwatosa.

WYOMING

DELEGATES FROM THE SECTIONS

PRACTICE OF MEDICINE
George D. Head, Minneapolis.

SURGERY, GENERAL AND ABDOMINAL
Jabez N. Jackson, Kansas City.

OBSTETRICS, GYNECOLOGY AND ABDOMINAL SURGERY
F. F. Simpson, Pittsburgh.

OPHTHALMOLOGY
Walter B. Lancaster, Boston.

LARYNGOLOGY, OTOLOGY AND RHINOLOGY
George F. Keiper, Lafayette, Ind.

DISEASES OF CHILDREN
Isaac A. Abt, Chicago.

PHARMACOLOGY AND THERAPEUTICS
A. D. Hirschfelder, Minneapolis.

PATHOLOGY AND PHYSIOLOGY
E. R. Le Count, Chicago.

STOMATOLOGY
William C. Fisher, New York

NERVOUS AND MENTAL DISEASES
Hugh T. Patrick, Chicago.

DERMATOLOGY
George MacKee, New York.

PREVENTIVE MEDICINE AND PUBLIC HEALTH
W. S. Rankin, Raleigh.

GENITO-URINARY DISEASES
Granville MacGowan, Los Angeles.

ORTHOPEDIC SURGERY
John Ridlon, Chicago.

GASTRO-ENTEROLOGY AND PROCTOLOGY
William VanValzah Hayes, New York City.

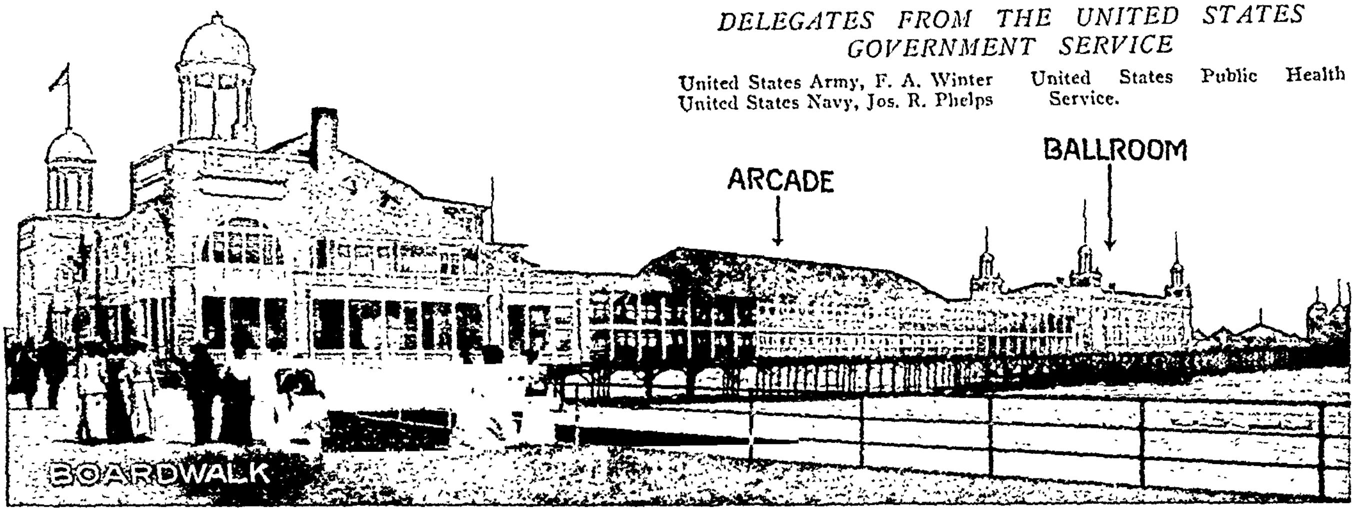
United States Army, F. A. Winter
United States Navy, Jos. R. Phelps
United States Public Health Service.



The Steel Pier—Opening Meeting, Registration and Exhibits.

ATLANTIC CITY· THE SUNRISE CITY OF AMERICA

Atlantic City, the world's best known health and pleasure resort, is built on an island of virgin sand 10 miles long and from one-fourth to 1 mile in width, over 5 miles from the shore line of New Jersey, with intervening tide water bays, thoroughfares and salt meadows. Owing to the peculiar contour of the New Jersey coast, Absecon Island faces almost directly south, which gives continuous sunshine to the entire beach front and Boardwalk from sunrise to sunset. About 90 miles at sea the Gulf Stream tempers the surrounding waters and heats the cold wintry winds that cross its ever moving path. Surrounded by water that, in winter, is many degrees warmer than the cold blasts of the north; in summer, with a temperature below the warm winds of the interior; and aided by her southerly exposure, Atlantic City's has a climate that is 10 to 15 degrees cooler than the nearby inland cities in summer and with the same variation of warmth in winter.

MOSQUITOES EXTERMINATED

The salt meadows in the rear have been so thoroughly drained and ditched by the Mosquito Commission of New Jersey that stagnant pools are entirely unknown and the proverbial New Jersey mosquito is practically a thing of the past for Atlantic City. The Anopheles has never been seen in Atlantic City, hence malaria is unknown and never existed here.

THE SUNSHINE RESORT

The average annual sunshine in Atlantic City is reported by the United States Weather Bureau at 61 per cent. as contrasted to 50 per cent. in many other places. With a freedom from factory smoke and dust our sunshine is perfectly bright and clear and gives an actinic action greatly in excess of the heavily ladened air of the interior where the particles of dust and soot absorb and reflect the violet and ultraviolet spectral rays. On this fact alone depends our greatest therapeutic climatic effects. For this reason sunburn is more common at the shore. Ocean air is particularly pure; it invigorates and gives new energy to the tired, anemic, and exhausted, to the convalescent and pleasure seekers who come seeking health, rest, appetite and sleep. Sunshine, pure air, health and pleasure are Atlantic City's commodities in trade—none others need apply.

THE BOARDWALK

Atlantic City's boardwalk is so well known to the world that it needs little comment. This unique structure extends 8 miles along the ocean front, 20 to 60 feet wide with its pine planks laid on massive concrete pillars, 8 to 10 feet above the strand. The smooth rolling chair paths and the new "herring bone" relaid decking remove the disagreeable features of the old boardwalk and make walking and roller chair riding a real pleasure. Except for six pleasure and recreation piers the ocean view from the boardwalk is unobstructed. A stroll along this structure is equivalent to a walk on the deck of an ocean liner with all of its invigorating salt breezes and stimulus, but lacking in the disagreeable rolling and tossing of the vessel. The city's side of the boardwalk is lined with metropolitan hotels, stores, amusements, theaters, movies and bathing establishments. Every nation of the globe is represented by the boardwalk merchants who are glad to show and sell Oriental, domestic and imported wares and articles of art and trade. This continued wall of buildings protects the boardwalk from the north winds of winter and the hot land breezes of summer. The boardwalk is beautifully lighted and on an evening stroll or roller chair ride under the scintillating rays of myriads of electric lights almost transform one to the realms of fairyland. Add to this the bewitching beauties of a full moon, shedding its rays on the bosom of the smooth Atlantic, and one forgets the trials and troubles of business cares and lapses into a soliloquy of sentimentalisms. Once having enjoyed this scene there is a constant longing to repeat and repeat.

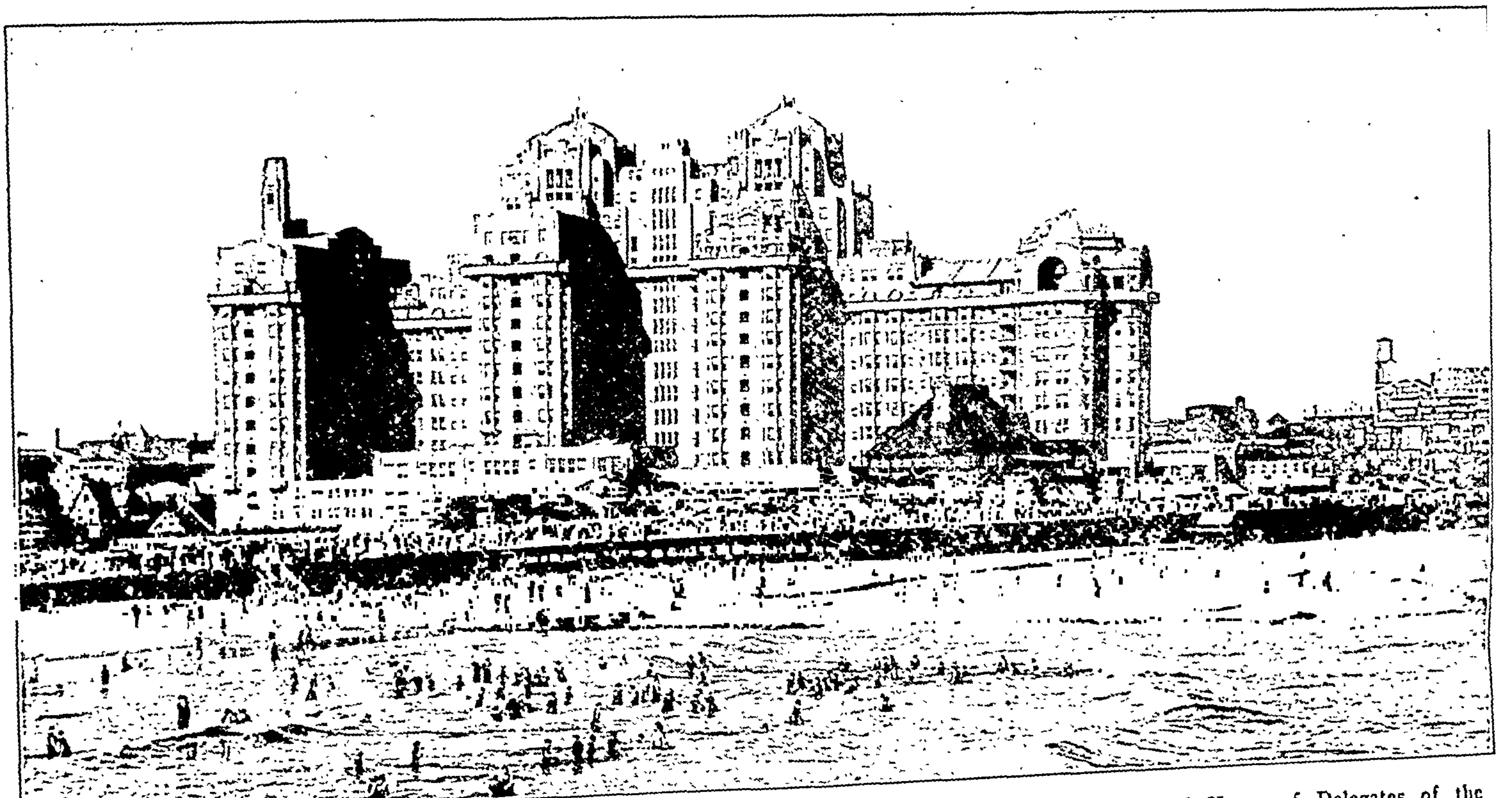
The rolling chair has become a fixture and is used as a vehicle of pleasure by the strong and well, and a comfort and convenience by the sick and convalescent. The boardwalk is patrolled day and night by a courteous, thoroughly trained police force that is constantly alert for the comfort and safety of visitors. When the crowds are largest and the ever moving kaledioscopic mass of people passes to and fro, disorder is unknown, for the atmosphere of happiness, good cheer and comradeship prevails and conventionalities are forgotten. "As safe at midnight as at noon" is the sentiment here. Twenty-four rest pavilions are provided on the ocean side where one can enjoy an easy chair and view the ocean or boardwalk.

THE HOTELS

Atlantic City has a class of hotels that is unexcelled in the world as to structure, service, comfort and cuisine. Three new million dollar structures are now being planned for the boardwalk, while others will follow in the near future. There are about twelve hundred hotels and boardinghouses that accommodate the transient thousands at prices within the reach of all. These hotels conform to the rules of an up-to-date Hotel Men's Association that provides fair treatment and honest dealing for every visitor.

BATHING

The bathing beach is one of the safest and best in the world and runs with a gradual slope to deep water. Life lines are unnecessary. The bathing beach is patrolled during bathing hours by life guards with police power who have at their command life boats and other necessary appliances. Four hospital emergency tents fully equipped and manned by competent registered surgeons and nurses are ready for the treatment of bathing accidents and minor injuries. Drownings are practically unknown in the patrolled areas. There are over thirty bathing establishments, many of which are equipped with tiled floors, showers and treatment rooms.



View of Atlantic City's famous boardwalk and the beach showing the Traymore Hotel, meeting place of House of Delegates of the American Medical Association for this session.

RECREATION

The finest theatrical productions are shown in Atlantic City. There are excellent provisions for boating, fishing and golf. Nowhere do opportunities for recreation exist that surpass those of America's chief vacation city.

THE CITY WATER SUPPLY

The municipal water supply comes from thirty-two artesian wells and cedar streams on the mainland 8 or 10 miles from Atlantic City. The artesian wells are driven through a deep bed of sand, gravel and an impervious clay bed where they tap an absolutly pure and uncontaminated water supply. These wells supply 6,000,000 gallons of water daily—enough for Atlantic City's use in her dullest times. The surface supply comes from streams that flow through virgin cedar forests and a watershed that is owned and controlled by Atlantic City and on which there are no habitations. This water is pure, safe and free from all contamination and is carried into a storage basin of nearly 300 acres area and from which water is carried as an auxiliary supply to the artesian water as the seasons' demands increase or special emergency requires. Monthly analyses covering a period of two years show a complete absence of bacteria and a sterile water from the surface sources. As a positive preventive against possible accidental contamination of the surface supply, three-tenths of one part per million of chlorin is used, even though unnecessary. The artesian and surface supplies are free from odors and taste and can be used at all times in unlimited quantities without stomach or intestinal disturbances or danger of disease. The large hotels have their own artesian wells driven to a depth of 850 feet from which an absolutely pure sparkling potable water is obtained. The general water supply of the city and hotels is free from lime salts and is a soft water. Analyses show only two grains of dissolved solids per U. S. gallon. With conditions of this kind it is positively unnecessary for visitors to buy bottled waters for table use.

Atlantic City's sewage is carried by a gravity system to central pumping plants where it is screened, chlorinated and pumped seven miles back of the city where it is properly disposed in thoroughfare waters.

RESIDENTIAL SECTIONS

A trip to Atlantic City is not complete without a visit to the shopping and residential sections. With 50 miles of well paved asphalt, bituminous, wood block and brick streets no cleaner or better drained city can be found. The main surface drainage is cared for by a large drainage conduit running the full length of the city to tidewater at both ends. Over 60,000 people make Atlantic City their permanent home, for they have found this the healthiest climate in the world. There are thirteen public schools; five national banks and six trust companies; thirty-five churches of every religious denomination; a white and colored Y. M. C. A.; up-to-date Atlantic City Hospital and a new Municipal Hospital for contagious diseases; a modern fire department with 180 paid firemen who have at command the most modern motorized equipment; a high pressure main in the boardwalk and hotel district; two yacht clubs with more than 400 yachts and power boats; an up-to-date chamber of commerce and publicity bureau for promoting the city's welfare.

A CHANCE TO FLY

Atlantic City now presents the first aeroplane schedule to New York, Philadelphia and other cities. By it one can fly to Philadelphia in 25 minutes and to New York in 50 minutes and at rates not in excess of taxi rates for the same trips. Aviation trips are permanent features of Atlantic City's pastimes. Aeroplanes are seen at all hours of the day making trips to and fro along the beach front and over the city. The entire month of May, 1919, will be given over to an international aviation meet the like of which has never been seen in America. The new aviation field under the municipal control of Atlantic City is one of the largest in the country where safe landings can be made on the land or adjoining water of the bay or thoroughfare. Where time, pleasure or adventure are factors, the Atlantic City aeroplane routes will soon become very popular.

Excellent automobile roads lead from Philadelphia, New York, and other points to Atlantic City. Some of these are in process of rebuilding by the state of New Jersey and when finished no better concrete roads will be known. The United States government has dredged the inlet channel to a depth of 12 feet at low tide and Atlantic City is providing modern docking facilities for yachts and pleasure craft.

On your first visit you like Atlantic City, but when you come a second time you find it irresistible and have that contagious longing for the boardwalk, the beach, the sea baths, the swimming pools, the golf courses, and the stimulating, appetizing, soporific fresh air and sunshine. Atlantic City is now as popular in winter as in summer. It is an all year resort. All of the beach front hotels are open both winter and summer. With hotel facilities the very best; with a unique boardwalk and rest pavilions and climatic conditions unexcelled, is it any wonder that the world plays in Atlantic City and that her citizens have justly adopted the *slogan:* "ATLANTIC CITY ALL THE TIME."

REGISTRATION

The Importance of Registering Early—A Few Suggestions Which Will Facilitate Registration

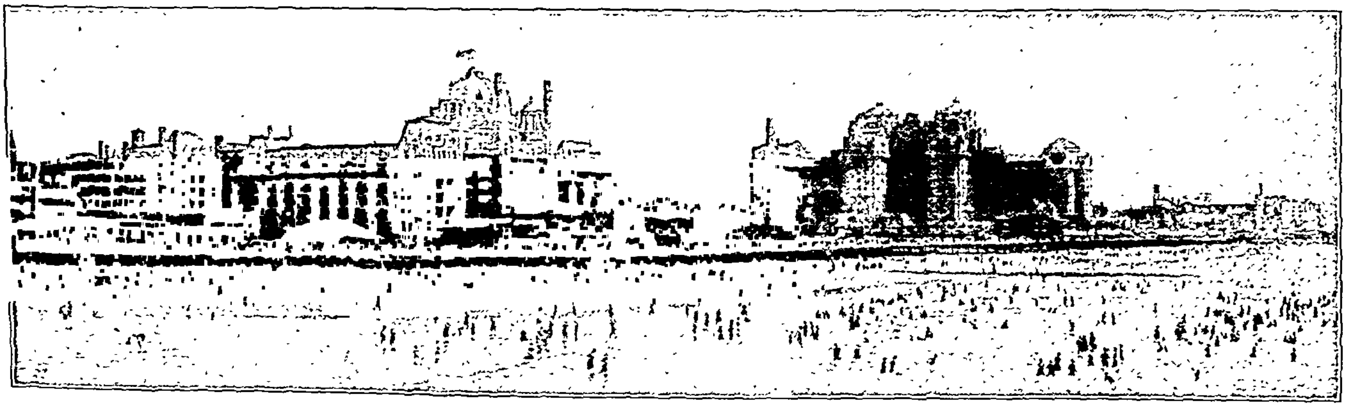
The Bureau of Registration will be located in the Ball Room of the Steel Pier. A committee of local physicians will assist those desiring to register. A branch postoffice will be opened, and a bureau of information established in connection with the Registration Bureau. Here the conventionist may secure copies of the *Daily Bulletin* which announces the names of visitors and other important convention material.

Every one who registers will be required to fill out completely the spaces on both parts of the double registration cards, which will be found on the tables in front of the Registration Bureau. These entries should be written very plainly, or printed, as the cards are given to the printer to use as "copy" for the *Daily Bulletin.*

1. Fellows who have their pocket cards with them can be registered with little or no delay. They should present the filled out registration card, together with their pocket card, at one of the windows marked "Registration by Pocket Card." There the clerk will compare the two cards, stamp the pocket card and return it, and supply the Fellow with a copy of the official program and other printed matter of interest to those attending the annual session.

2. Those Fellows who have forgotten their pocket cards should present the filled in registration card at the window marked "Paid—No Card." The work of registration at this window will be conducted as rapidly as possible; but the necessity of finding the Fellow's name on the Fellowship roster may occupy a considerable time and will occasion inconvenience to those who neglect to bring their pocket cards with them.

3. The Fellow whose 1919 dues are unpaid should present his filled in registration card with the amount of his Fellowship dues ($5) at one of the windows marked "Cash." Here, too, there will be occasioned some delay; but the work of registering will be conducted as promptly as possible.



The panorama along the boardwalk. On the extreme left, the Shelburne Hotel; in the left foreground, the Hotel Dennis; left center, the Marlborough-Blenheim; at the right center, the Traymore Hotel and the Brighton Casino.

4. It will assist in registering if those who desire to qualify as Fellows will file their applications and qualify as Fellows by writing directly to the American Medical Association, 535 North Dearborn Street, Chicago, so that their Fellowship may be entered not later than June 1. Any applications received later than June 1 will be given prompt attention, but the Fellowship certificate and pocket card may not reach the applicant in time so that he can use this card in registering at the Atlantic City Session, and he may be required to make a second payment of his Fellowship dues, which must be held until the records at headquarters can sulted after the close of the session, when any will be adjusted.

If, however, a member of the Association neglects to qualify as a Fellow before reaching Atlantic City he may be entered as a Fellow at the meeting by following procedure. He should present a filled in registration card, together with a formal application for Fellowship at the window marked "New Fellows." These applications for Fellowship can be obtained at Window No. 1 of the Registration Bureau or from the members of the Committee on Registration. In order to qualify as a Fellow, the applicant must be officially reported as a member of the constituent association of the state in which he resides, and in addition to filing this formal application, he must pay his annual Fellowship dues for the current year; if already a subscriber to The Journal, with his subscription paid for a term to or beyond Jan. 1, 1920, no additional payment is necessary. If subscription is not paid in full for the current year, the payment of a sum to extend it to Jan. 1, 1920, is required.

The registration of new Fellows will be greatly facilitated if, before leaving their homes for Atlantic City, they will provide themselves with certificates of membership issued by the secretary of their state association, certifying to their membership in good standing for 1919 in the state and county branches of the organization. A failure to provide themselves with such a certificate will necessarily subject them to some delay in registering with its consequent annoyance not only to themselves but also to others desiring to record their attendance.

POSTOFFICE

An Association Postoffice will be maintained in connection with the Registration Bureau in the Ball Room on the Steel Pier. Guests are requested to order mail addressed to them "Care American Medical Association, Steel Pier, Atlantic City, N. J.," or to their hotels, as preferred.

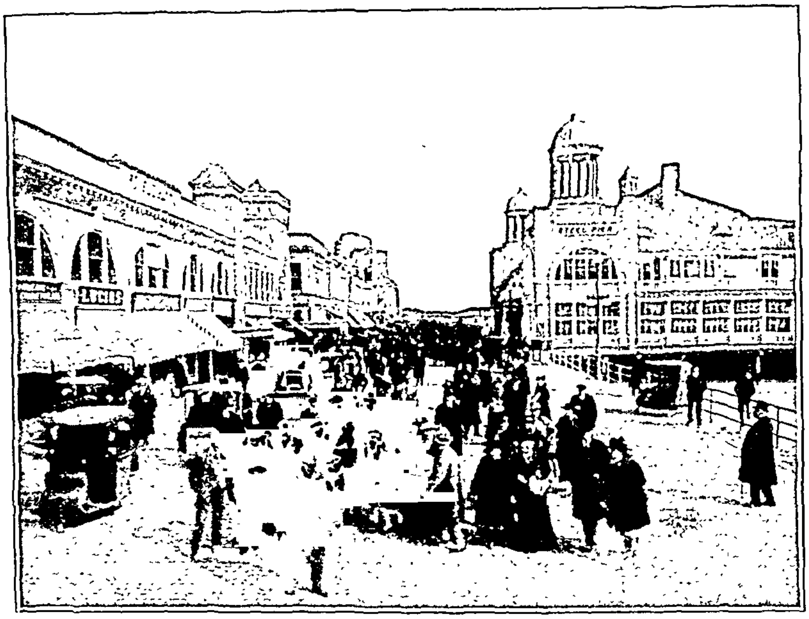
TRANSPORTATION

Summer Tourist Rates Announced

The United States Railroad Administration, through chairmen of Passenger Traffic Committees, has advised that Summer Tourist rates will be in effect to Atlantic City, N. J., tickets being on sale from May 15 to September 30, with final return limit Oct. 31, 1919. Round trip fares from Chicago, it is announced, will be $49.02, and from St. Louis $57.96. However, there may be additional charge to cover war tax and extra fares. From other points round trip fares will be constructed on the basis of 90 per cent. of the double one way fare to Atlantic City, except that if this makes less than double the one way fare to Philadelphia, then the through rate to Atlantic City will be double the fare to Philadelphia. Those who are planning to go to Atlantic City for the Victory Meeting should consult the local ticket agent in their home town, in order to obtain full information regarding rates, time limits, extensions and stop-over privileges which may be had on railway tickets to Atlantic City. It is advisable to make these inquiries at an early date as local ticket agents may have to ask for the information needed and, except in the larger cities, it may be necessary to obtain a special form of ticket from some central ticket office. Neglecting to make such inquiry until just before the time for leaving home may make it necessary for the ticket agent to sell a full fare, one way ticket, since he may have neither the proper form nor the authority to sell these summer rate tickets. The importance of an early inquiry is emphasized.



Boardwalk showing entrance to the steel pier and the seaside block.

The American Medical Special

CHICAGO TO ATLANTIC CITY

"The American Medical Special" will be run for the accommodation of the Fellows of the Association who desire to go in a party from Chicago to Atlantic City to attend the Victory Meeting. This train is announced to run over the Pennsylvania Railway, leaving the Union Station, corner of Canal and Adams Streets, Chicago, at 10:30 a. m., Sunday, June 8. It is scheduled to arrive at Atlantic City on the following morning about 10 o'clock, in ample time to permit of being comfortably located at the hotel before the luncheon hour.

The train will be made up entirely of Pullman sleeping cars and will be provided with club and dining car service. No effort will be spared to provide accommodations so that the journey may be as comfortable and as pleasant for the Fellows who use this train as is possible. It will be noted the equipment is similar to that which has been placed at service of the Fellows on previous occasions. The one way fare from Chicago to Atlantic City on trains of this equipment is $33.69, and the round trip fare between Chicago and Atlantic City, good returning until October 31, and permitting of stop-over at any point enroute, will be $58.34. The cost of a lower berth, one way, is $5.40; upper berth, $4.32; drawing room, accommodating three persons, $19.44. The rates here quoted include war tax.

The attendance at the Victory Meeting promises to be large and those who are planning to attend will undoubtedly be attracted by the accommodations offered on this special. Without doubt, the available space will be quickly reserved, consequently, Fellows are urged to write at once to Mr. C. L. Kimball, Asst. General Passenger Agent, Pennsylvania Railroad, Room 841, 175 Jackson Boulevard, Chicago, in order that they may obtain further information and make reservation for sleeping car accommodations if they desire to use this train. Physicians from other cities of the West and Middle West may arrange to continue their trip from Chicago to the convention city on this train.

ACCOMODATIONS OFFERED BY ATLANTIC CITY HOTELS

Although Atlantic City is a city of hotels and can easily accommodate all who attend the annual session, Fellows are urged to make their hotel reservations early. This is especially advisable this year because many of the beach-front hotels are already booked practically to their full capacity for the week of the annual session.

The subcommittee on hotels of the local committee on arrangements, however, anticipates no trouble in accommodating with comfortable hotel accommodations those who visit Atlantic City, June 9 to 13. The Atlantic City physicians simply ask that reservations shall be arranged, as far as practicable, before the visitor starts for Atlantic City. Just as one is never so much alone as when he is a stranger in a large crowd, so the difficulties of securing hotel facilities in a city of hotels is accentuated. It will be more convenient on arriving at Atlantic City, to go at once to a hotel which is expecting you, rather than to make a round of hotels, finding a number of them completely filled, and finally being compelled to take the first lodgings which are found in a hurried personal search. The list of hotels appearing in this issue locates the different hotels and gives their rates. Make your selection, write to the manager, and take with you to Atlantic City his reply, assuring you that a reservation has been made for your use. The subcommittee on hotels, of the local committee on arrangements, Dr. D. B. Allman, chairman, will endeavor to assist you to get into communication with the manager of a hotel where you can make reservations if you find difficulty, by direct correspondence, in securing the lodgings you desire. In writing to Dr. Allman, Fellows should state the number in their party, when they expect to arrive in Atlantic City, how long they plan to remain and approximately the amount per day per person they are prepared to pay for hotel expenses. One may well leave to the local committee, as far as practicable, the choice of the hotel.

SOCIAL EVENTS AND SPECIAL MEETINGS

(Note.—The official badge will be required for admission to entertainments and other places to which entrance is granted to those in attendance on the annual session.)

MONDAY

The fifth tournament of the American Medical Golfing Association will be played on the links of the Atlantic City Golfing Club. Luncheon will be served at the Club House from 12 to 2, and the annual dinner of the Association as well as its business meeting will be held in the evening. Any Fellow of the American Medical Association becomes a Fellow of this Association automatically on acceptance of its by-laws and the payment of the enrolment fee of $2. For further information address Dr. Will Walters, secretary-treasurer, 1414 Chicago Avenue, Evanston, Ill. Visiting foreign physicians are invited to attend this tournament.

TUESDAY

The opening general meeting will be convened in the Music Hall on the Steel Pier at 8:30 p. m: In addition to the usual opening program, including the President's address, the foreign guests will be formally introduced.

WEDNESDAY

A Victory Meeting will be held in the Music Hall on the Steel Pier, convening at 8:30 p. m. At this meeting national organizations, the activities of each of which have definite medical interest, will be represented by speakers of their choice. Each speaker will be asked to respond with a short address on the general subject of American medicine and surgery as it responded in service under war conditions.

THURSDAY

At 2 in the afternoon, two large general meetings will convene on the Garden Pier. At these meetings representatives of the medical profession of foreign countries, and particularly those allied to the United States in the World War, will make addresses. At one of these meetings the subjects discussed will pertain to general medicine; the other will be devoted to surgical topics.

PRESIDENT'S RECEPTION

On Thursday evening at 8:30 o'clock, again on the Garden Pier, there will be a reception to the President of the Association and to the foreign guests.

Panorama from the Casino on the steel pier. Reading from left to right are: the Blackstone Hotel, bathing beaches, the Globe Theater; the tall building at the right, the St. Charles Hotel, and at the extreme right, the Breakers Hotel. The beach indicated is one of the best bathing beaches in Atlantic City.

INVITED GUESTS FROM FOREIGN COUNTRIES

By the authority of the Hon. Newton D. Baker, Secretary of War of the United States of America, the American Medical Association has requested the governments of the nations allied to the United States in the prosecution of the World War, through their several embassies and legations, to send representative delegations of the medical professions of their countries to participate in the coming annual session of the Association. A prominent feature of the 1919 annual session will thus be the bringing together of a representative medical assemblage to confer on the medical knowledge which has grown out of the war; to elaborate plans for cooperative interallied graduate study and research, and to cement the bonds of an enduring friendship among physicians. A number of the governments have indicated their purpose to appoint the delegates requested. Some of them have already officially advised the American Medical Association of those who have been appointed to represent the medical profession of their countries. The coming annual session will be indeed a Victory Meeting since it will bring together representatives of the medical profession of all the allied nations as well as of a number of the neutral powers. Belgium, Great Britain, Cuba, Norway and we understand France already have noted physicians in the United States.

HEADQUARTERS FOR WOMEN PHYSICIANS

Hotel Holmhurst will be the headquarters for women physicians who attend the Victory Meeting. Women physicians may secure reservations by writing directly to the management of this hotel. The dinner for women physicians will be held on Wednesday evening, June 11, at the Marlborough-Blenheim at 6:30 o'clock. The subscription price is $4 a cover. Contributions should be sent on before June 6 to Dr. Clara K. Bartlett, 4301 Atlantic Avenue, Atlantic City, N. J. Attention is called to the corrected date here given, as this dinner previously was announced for the evening of Monday, June 9.

SECTION DINNERS AND ALUMNI MEETINGS

While the program for the Atlantic City meeting is already well filled, it may be that certain sections will want to return to the custom of holding a social gathering which will not conflict with the sections. Alumni of medical schools are planning to revive their annual reunions. The Local Committee on Arrangements, through its subcommittee on Section Entertainments, Samuel Barbash, chairman, will cooperate with officers of sections and through the subcommittee on Alumni Entertainments, Worth Clark, chairman, will assist in arranging the latter functions.

MEETINGS OF NON-AFFILIATED ORGANIZATIONS

Medical Veterans of the World War

The temporary officers of the Medical Veterans of the World War are arranging for a meeting to be convened in Atlantic City on the afternoon of Tuesday, June 10, for the purpose of effecting a permanent organization. Blank forms for making application for membership in this organization may be obtained either from the office of the temporary secretary, Col. F. F. Russell, Medical Corps, U. S. Army, Army Medical School, Washington, D. C., or from the temporary president, Dr. Hubert Work, Pueblo, Colo., or by sending a self-addressed envelope to the headquarters of the American Medical Association. These forms have also been placed in the hands of those physicians who served as medical aids to the governors of the several states in the establishment and conduct of the medical advisory boards, and it is planned to shortly place a supply with the secretaries of the several constituent state associations. Those who are eligible for membership and who desire to make application should obtain and use these forms. Each application should be accompanied with a fee of one dollar, to apply to the expenses of organization. It is further planned to hold a meeting of this organization on the evening of Friday, June 13, at Atlantic City.

Meetings of Special Societies

In addition, the following organizations have announced meetings to be held at Atlantic City during the days immediately preceding the dates for the scientific assembly of the Association: American Academy of Medicine; American Association of Anesthetists; American Association of Industrial Physicians and Surgeons; American Association of Teachers of Diseases of Children; American Proctologic Society; American Therapeutic Society. During the week following the VICTORY MEETING of the Association, the Congress of American Physicians and Surgeons will hold its triannual conference at Atlantic City. At this time, June 16 to 17, the following organizations will hold their meetings: American Association of Genito-Urinary Surgeons; American Association of Pathologists and Bacteriologists; American Association of Physicians; American Climatological and Clinical Association; American Dermatological Association; American Neurological Association; American Ophthalmological Society; American Pediatric Society; American Psychopathological Association; American Society of Tropical Medicine; American Surgical Association. On June 18 to 20, the American Medico-Psychological Association will meet at Philadelphia.

THE SCIENTIFIC EXHIBIT

The feature of the Scientific Exhibit at the Atlantic City meeting will be the exhibition by the different government departments of scientific work done during and in connection with the war. As the session is to be a VICTORY MEETING, it was decided to make the Scientific Exhibit center largely around the work done for and by the government. Accordingly invitations were sent to each of the government departments, asking them to prepare and present an exhibit of the work done. Nine bureaus or division belonging to six departments have accepted the invitation and will present exhibits. This is in addition to the customary exhibit of individual research. The Scientific Exhibit promises to be one of unusual value and interest. The exhibits of the Army, Navy and Public Health Service will be located in the Exposition Building, Board Walk and Kentucky Avenue. All other exhibits will be on the ground floor of the Casino, on the Steel Pier. The exhibitors are as follows:

Government Exhibits

SHOWING THE WORK OF THE VARIOUS DEPARTMENTS AND BUREAUS RELATING TO HEALTH

Medical Department, U. S. Army.
Bureau of Medicine and Surgery, U. S. Navy.
United States Public Health Service.
Department of Agriculture, Bureau of Chemistry.
Department of Agriculture, Bureau of Entomology.
Department of Commerce, Bureau of Standards.
Department of Commerce, Bureau of the Census.
Department of Labor, Children's Bureau.
American Red Cross.

Individual Exhibitors

DR. EMIL G. BECK, Chicago: Stereoscopic Roentgenograms and Stereo-Lunnier Photography of Specimens.

ROENTGEN-RAY DEPARTMENT, BELLEVUE AND ALLIED HOSPITALS, New York: Roentgenology—Teaching Methods and Specimens.

DRS. JAMES T. CASE AND PAUL ROTH, Battle Creek Sanitarium, Battle Creek, Mich.: Dietetic Management of Diabetics; Bergell Test; Electrocardiograms; Roentgenograms.

DR. J. SHELTON HORSLEY, Richmond, Va.: Illustrations of Operations on the Gastro-Intestinal Tract Based on Physiology of the Stomach and Intestines.

LYING-IN HOSPITAL OF THE CITY OF NEW YORK: Museum Specimens and Wall Charts.

DR. MYRON METZENBAUM, Cleveland: Nasal Deformities Showing Photographs of Cases Before and After Operations.

THE MAYO CLINIC, Rochester, Minn.: Scientific Material from the Mayo Clinic Staff.

DR. HIDEYO NOGUCHI, Rochefeller Institute, New York: Experimental Work on Yellow Fever.

PRUDENTIAL INSURANCE COMPANY, Newark, N. J.: Statistical Charts on Influenza.

ST. LUKE'S HOSPITAL, New York: Roentgen-Ray Plates and Prints.

DR. FENTON B. TURCK, New York: Experimental Shock, Experimental War Wounds and Other Injuries; Pneumonias.

DR. D. T. QUIGLEY, Omaha: Results of Treatment by Radium.

DR. A. S. WARTHIN, Ann Arbor, Mich.: Pathology of Mustard Gas Poisoning; Photographic Specimens.

American Medical Association

COUNCIL ON PHARMACY AND CHEMISTRY: Charts and Samples Showing Activities of the Council with Copies of Publications.

CHEMICAL LABORATORY: Charts and Samples Showing Chemical Work of Laboratory.

PROPAGANDA DEPARTMENT: Educational Charts and Literature on Nostrums and Quackery.

COUNCIL ON HEALTH AND PUBLIC INSTRUCTION: Educational Pamphlets, Charts and Diagrams on Public Health.

Moving Picture Exhibit

The moving picture theater on the second floor of the Casino will be conducted as a part of the Scientific Exhibit. from 9 a. m. to 3 p. m. on Tuesday, Wednesday, Thursday and Friday, June 10, 11, 12 and 13. Moving picture films showing the work of medical officers in the Army and Navy and the activities of the Public Health Service will be shown, also material by private exhibitors. An illustrated talk will be given each day by the Propaganda Department of THE JOURNAL. A detailed program of the moving picture exhibit will appear in the official program.

PRELIMINARY PROGRAM OF THE SCIENTIFIC ASSEMBLY

PROGRAM OF THE OPENING MEETING

STEEL PIER, MUSIC HALL

Tuesday, June 10, 8:30 p. m.

Music.

Call to Order by the President, Dr. Arthur Dean Bevan, Chicago.

Invocation. Abner H. Lucas, Ph.D., D.D., Atlantic City.

Announcements. Dr. Emery Marvel, Chairman of the Local Committee of Arrangements.

Address of Welcome. Hon. Harry Bacharach, Mayor, Atlantic City.

Address of Welcome. Dr. Thomas Harvey, Orange, N. J., President of the Medical Society of New Jersey.

Address. Hon. Walter E. Edge, Governor of New Jersey, U. S. Senator-Elect.

Music.

Introduction and Installation of President-Elect Alexander Lambert, New York.

Address. Dr. Alexander Lambert.

INTRODUCTION OF DELEGATES FROM OTHER COUNTRIES

Music.

THE PROGRAMS OF THE SECTIONS

Outline of the Scientific Proceedings — The Preliminary Program and the Official Program

The following papers are announced to be read before the various sections. The order here is not necessarily the order which will be followed in the Official Program nor is the list complete. The Official Program will be a pamphlet similar to those issued in previous years, and will contain the final program of each section with abstracts of the papers, also lists of committees, programs of the General Meeting, lists of entertainments, map of Atlantic City and other information. To prevent misunderstandings and to protect the interest of advertisers, it is here announced that this Official Program will contain no advertisements. It is copyrighted by the American Medical Association and will not be distributed before the session. A copy will be given to each Fellow on registration.

SECTION ON MISCELLANEOUS TOPICS

There will be two meetings for the discussion of Industrial Medicine and Surgery—five or six additional papers are being considered. The completed program will be announced in the Official Program.

MEETS IN BREAKERS, EGYPTIAN ROOM—ALL MEETINGS

Chairman—Harry E. Mock, Chicago.
Vice Chairman—David L. Edsall, Boston.
Secretary—Otto P. Geier, Cincinnati.

Wednesday, June 11—2 p. m.

Meeting Place—Breakers, Egyptian Room

SYMPOSIUM—SCOPE OF INDUSTRIAL MEDICINE AND SURGERY

Chairman's Address. Harry E. Mock, Chicago.

Preventive Surgery, as Demonstrated by Industrial Practice. William I. Clarke, Jr., Worcester, Mass.
Discussion to be opened by William O'N. Sherman, Pittsburgh; Charles G. Farnum, Peoria, Ill., and Arthur M. Corwin, Chicago.

Industrial Medical Practice and Sickness Prevention as a Factor in Public Health. C. E. Ford, New York.
Discussion to be opened by William Alfred Sawyer, Philadelphia.

The Enlarged Program of the U. S. Public Health Service, Division of Industrial Hygiene and Medicine.
Joseph W. Schereschewsky, Washington, D. C.

International Aspect of Public Health as Related to Industrial Hygiene.
George A. Soper, Sanitary Corps, U. S. Army.

Discussion of Papers 4, 5 and 6.

General Discussion of the Symposium.
Discussion to be opened by Francis D. Patterson, Harrisburg, Pa.

Friday, June 13—2 p. m.

Meeting Place—Breakers, Egyptian Room

SYMPOSIUM—SOME FUTURE ASPECTS OF INDUSTRIAL MEDICINE AND SURGERY

Modernizing Our Medical College by Adding Departments of Industrial Medicine and Public Health.
Otto P. Geier, Cincinnati.
Discussion to be opened by David L. Edsall, Boston.

Medical Service for the Small Industrial Units.
Clarence D. Selby, Toledo, Ohio.

SECTION ON PRACTICE OF MEDICINE

MEETS IN ST. PAUL'S CHURCH, AUDITORIUM—ALL MEETINGS

OFFICERS OF SECTION

Chairman—Walter L. Bierring, Des Moines, Iowa.
Vice Chairman—C. G. Jennings, Detroit.
Secretary—J. S. McLester, Birmingham, Ala.
Acting Secretary—Joseph H. Pratt, Boston.
Executive Committee—Roger S. Morris, Cincinnati; Henry A. Christian, Boston; Lawrence Litchfield, Pittsburgh.
(Stenographer—Dr. W. W. Bellamy, Boston)

Wednesday, June 11—9 a. m.

Meeting Place—St. Paul's Church, Auditorium

1. Chairman's Address: Relations of Internists to Military Medicine. Walter L. Bierring, Des Moines, Iowa.
2. The Basal Metabolism and Alimentary Hyperglycemia Test of Thyrotoxicosis.
W. G. McCaskey, Fort Wayne, Ind.
Discussion to be opened by Alfred C. Crofton, Chicago, and John E. Greiwe, Cincinnati.
3. The Value of the Basal Metabolic Rate in the Diagnosis of Hyperthyroidism.
Henry S. Plummer, Rochester, Minn.
4. The Clinical, Functional and Pathologic Observations on Some Cases of Chronic Nephritis.
James P. O'Hare, Boston.
Discussion to be opened by Leonard G. Rowntree, Minneapolis.
5. Dietotherapy in Metabolic Disease.
Frederick M. Allen, New York.
6. A Note on the Recognition of Tropical Sprue in the United States. Edward J. Wood, Wilmington, N. C.
Discutssion to be opened by Douglas Vanderhoof, Richmond, and Andrew W. Sellards, Boston.
7. Hypertension in Women with Remarks on Etiology, Prognosis and Treatment. David Riesman, Philadelphia.

Thursday, June 12—9 a. m.

Meeting Place—St. Paul's Church, Auditorium

Election of Officers

8. The Clinical Study of Pulmonary Excursion.
Charles F. Hoover, Cleveland.
9. Errors in the Diagnosis of Chronic Pulmonary Tuberculosis.
Thomas McCrae and Elmer H. Funk, Philadelphia.
10. Studies of Arthritis in the Army.
Ralph Pemberton, Philadelphia.
11. The Psychic Factor as an Element in Temperature Disturbance as Shown by Some Observations in the Selective Draft. Frank B. Wynn, Indianapolis.
Discussion to be opened by Charles D. Humes, Indianapolis.

12 The Importance of Physical Development in Cases of Effort Syndrome. Bertnard Smith, Los Angeles.
Discussion to be opened by Eveleth W. Bridgeman, Baltimore, and Francis W. Peabody, Boston.

13. Pericarditis as a Complication of Pneumonia Based on Three Hundred and Fifty Necropsies.
Willard J. Stone, Toledo, Ohio.

14. Effective and Practical Treatment of Malaria to Disinfect Infected Persons and Prevent Relapse.
Charles C. Bass, New Orleans.

Friday, June 13—9 a. m.

Meeting Place—St. Paul's Church, Auditorium

SYMPOSIUM ON MILITARY MEDICINE

BY INVITATION, WILLIAM S. THAYER, BALTIMORE, WILL PRESIDE

15. Problems of the Division.
Maurice C. Pincoffs, Chicago.

16. Problems of the Corps and Army.
George Draper, New York.

17. Poisonous Gases: Immediate Recognition and Evacuation of Gas Cases. Richard Dexter, Cleveland.

18. Poisonous Gases: Later Effects.
Alfred E. Cohn, New York.

19. Poisonous Gases: Pathology.
Alwin M. Pappenheimer, Hartsdale, N. Y.

20. Influenza. Warfield T. Longcope, New York.

21. The Treatment of Chest Injuries.
Marion A. Blankenhorn, Orrville, Ohio.

22. Aviation. Thomas R. Boggs, Baltimore.

23. Nephritis in the Soldier. Reginald Fitz, New York.

24. The Work of the Group Consultant.
Joseph A. Capps, Chicago.

25. The Work of the Group Consultant
Joseph Sailer, Philadelphia.

SECTION ON SURGERY, GENERAL AND ABDOMINAL

MEETS IN FIRST PRESBYTERIAN CHURCH, AUDITORIUM—ALL MEETINGS

OFFICERS OF SECTION

Chairman—John T. Bottomley, Boston.
Vice Chairman—LeGrand Guerry, Columbia, S. C.
Secretary—Eugene H. Poole, New York.
Acting Secretary—George P. Müller, Philadelphia.
Executive Committee — E. Wyllys Andrews, Chicago; William D. Haggard, Nashville, Tenn.; E. Starr Judd, Rochester, Minn.

(Stenographer—Mrs. M. C. Repp, Philadelphia)

Wednesday, June 11—2 p. m.

Meeting Place—First Presbyterian Church, Auditorium

1. Chairman's Address. John T. Bottomley, Boston.

2. Traumatic or Wound Shock.
Walter B. Cannon, Boston.

3. Hemorrhage and Transfusion.
Bertram M. Bernheim, Baltimore.
Discussion to be opened by George W. Crile, Cleveland; Oswald H. Robertson, New York; Howard T. Karsner, Cleveland; Elmer J. Bissell, Rochester, N. Y., and Major G. Seelig, St. Louis.

4. "Débridement." Dean D. Lewis, Chicago.

5. Primary and Secondary Suture.
Eugene H. Pool, New York.
Discussion to be opened by Hugh Cabot, Boston; Fred W. Bailey, St. Louis; Wesley E. Drennan, Birmingham, Ala., and Frederick A. Besley, Chicago.

6. Gas Bacillus Infection.
Frederick T. Van Beuren, Jr., New York.

7. Sterilization of the Wound.
George A. Stewart, Baltimore.
Discussion to be opened by A. Depage, Belgium; James P. Hutchinson, Philadelphia; Arthur W. Elting, Albany, N. Y.; Henry H. M. Lyle, New York; James T. Pilcher, Brooklyn; Fred W. Bancroft, New York, and Hugh H. Trout, Roanoke, Va.

Thursday, June 12—9 a. m.

Meeting Place—First Presbyterian Church, Auditorium

Election of Officers

8. Opening Address. Charles H. Mayo, Rochester, Minn.

9. Brain Injuries. Harvey Cushing, Boston.
Discussion to be opened by Pedro Chutro, Buenos Aires; Kellogg Speed, Chicago; Harry H. Kerr, Washington, D. C., and Karl W. Ney, New Orleans.

10. Peripheral Nerve Injuries.
Charles H. Frazier, Philadelphia, and Samuel Silbert, New York.
Discussion to be opened by Martin B. Tinker, Ithaca, N. Y.; James F. Corbett, Minneapolis; Murray S. Danforth, Providence, R. I.; William W. Babcock, Philadelphia; Charles Bagley, Jr., Baltimore; Alfred W. Adson, Rochester, Minn., and Byron P. Stookey, Los Angeles.

11. Abdominal Injuries. George W. Crile, Cleveland.
Discussion to be opened by John B. Deaver, Philadelphia; John H. Gibbon, Philadelphia; Burton J. Lee, New York, and William Darrach, New York.

12. Chest Injuries. John L. Yates, Milwaukee.
Discussion to be opened by Arthur M. Shipley, Baltimore; William F. Verdi, New Haven, Conn., and Joseph G. Yocum, New York.

13. Maxillo-Facial Injuries. Vilray P. Blair, St. Louis.
Discussion to be opened by George E. deSchweinitz, Philadelphia; Harris P. Mosher, Boston; Robert H. Ivy, Milwaukee; William T. Coughlin, St. Louis, and George M. Dorrance, Philadelphia.

Friday, June 13—2 p. m.

Meeting Place—First Presbyterian Church, Auditorium

14. War Fractures. J. A. Blake, Paris

15. War Fractures. Maurice Heitz-Boyer, France.

16. War Fractures W. H. Groves, England.

17. Statistical Summary of War Fractures.
John B. Walker, New York.

18. Osteomyelitis After War Injury.
Pedro Chutro, Buenos Aires.

19. Restoration of Loss of Bone from Gunshot Wounds.
Fred H. Albee, New York.
Discussion to be opened by Frederick A. Besley, Chicago; George W. Hawley, Bridgeport, Conn.; Joseph R. Eastman, Indianapolis; Morris K. Smith, New York, and Ralph T. Knight, Minneapolis.

20. War Injuries of Joints. Vernon C. David, Chicago.
Discussion to be opened by Arthur M. Shipley, Baltimore; Burton J. Lee, New York, and Kellogg Speed, Chicago.

SECTION ON OBSTETRICS, GYNECOLOGY AND ABDOMINAL SURGERY

MEETS, WEDNESDAY AND FRIDAY, IN FIRST PRESBYTERIAN CHURCH, AUDITORIUM; THURSDAY, IN FIRST PRESBYTERIAN CHURCH, CHAPEL

OFFICERS OF SECTION

Chairman—Thomas J. Watkins, Chicago.
Vice Chairman—T. W. Keefe, Providence, R. I.
Secretary—Sidney A. Chalfant, Pittsburgh.
Executive Committee—Edward Reynolds, Boston; Howard W. Longyear, Detroit; Brooke M. Anspach, Philadelphia.

Wednesday, June 11—9 a. m.

Meeting Place—First Presbyterian Church, Auditorium

1. Chairman's Address: Gynecology and Abdominal Surgery.
Thomas J. Watkins, Chicago.

2. Analysis of Fifty Cases of Uterine Bleeding from Causes Other Than Malignancy or Myoma Treated by Radium.
Samuel M. D. Clark, New Orleans.

3. Treatment of Myoma Uteri with Radium.
John G. Clark, Philadelphia.

4. Radium Treatment in Carcinoma of the Cervix and Body of the Uterus.
Howard A. Kelly and Curtis F. Burnam, Baltimore.
Discussion on papers 2, 3 and 4 to be opened by H. C. Bailey, New York; Ernest C. Samuel, New Orleans, and A. H. Curtis, Chicago.

5. The End-Results in Over One Hundred Operations for Uterine Myoma (Operative Versus Roentgen-Ray Treatment). Arthur Stein, New York.
6. The Teaching Function of the Hospital: With Especial Reference to Gynecology. George Gray Ward, Jr., New York.
   Discussion to be opened by Brooke M. Anspach, Philadelphia.
7. Alternating, Periodical Swellings of the Ovary. Emil Ries, Chicago.

Thursday, June 12—9 a. m.

Meeting Place—First Presbyterian Church, Chapel

Election of Officers

8. Uterine Retrodisplacement as a Cause of Reflex Neuroses. Peter B. Salatich, New Orleans.
   Discussion to be opened by Edward E. Montgomery, Philadelphia.
9. A Clinical Study of the Treatment of Dysmenorrhea. Jennings C. Litzenberg, Minneapolis.
10. If Possible Prevent Sterilization in Young Women When Operating for Tubercular Peritonitis. J. Henry Carstens, Detroit.
    Discussion to be opened by Lewis S. McMurtry, Louisville.
11. The Specialty of Obstetrics. Henry P. Newman, San Diego.
    Discussion opened by Edward P. Davis, Philadelphia.
12. The Newer Methods of Cesarean Section: Their Indications: Results in Forty Cases (Lantern Demonstration.) Joseph B. DeLee, Chicago.
    Discussion to be opened by James W. Markoe, New York, and Charles E. Paddock, Chicago.
13. Etiology and Treatment of Pernicious Nausea and Vomiting of Pregnancy. Frank W. Lynch, San Francisco.
    Discussion to be opened by Alfred Baker Spalding, San Francisco.
14. The Treatment of Abdominal Pregnancy After the Fifth Month (Lantern Demonstration). Alfred C. Beck, Brooklyn.
    Discussion to be opened by John O. Polak, Brooklyn.
15. Aspiration and Pressure Treatment of Unopened Mammary Abscesses (Puerperal). John Gardiner, Toledo.
    Discussion to be opened by Richard C. Norris, Philadelphia.

Friday, June 13—9 a. m.

Meeting Place—First Presbyterian Church, Auditorium

16. Trendelenburg Ether Anesthesia in Pelvic Surgery (Lantern Demonstration). Donald Guthrie, Sayre, Pa.
    Discussion to be opened by Raleigh R. Huggins, Pittsburgh.
17. Abdominal Surgery Under Local Anesthesia (Lantern Demonstration). Robert E. Farr, Minneapolis.
18. The Treatment of Gunshot Wounds of the Abdomen. John H. Gibbon, Philadelphia.
    Discussion to be opened by Edward W. Meredith, Pittsburgh.
19. The Efficiency of Surgical Treatment in the Bleeding Type of Gastric and Duodenal Ulcer. Donald C. Balfour, Rochester, Minn.
20. A New Operation for Duodenal and Gastric Ulcers (Lantern Demonstration). J. Shelton Horsley, Richmond, Va.
    Discussion to be opened by Albert E. Halstead, Chicago, and George W. Crile, Cleveland.
21. Rational Surgery of Visceroptosis (Lantern Demonstration). Roland Hazen, Paris, Ill.
    Discussion by Robert T. Morris, New York.
22. The Better Methods of Wound Treatment. Henry O. Marcy, Boston.
    Discussion to be opened by Frederick A. Besley, Chicago.

SECTION ON OPHTHALMOLOGY

MEETS IN TRAYMORE, ROSE ROOM—ALL MEETINGS

OFFICERS OF SECTION

Chairman—Cassius D. Wescott, Chicago.
Vice Chairman—Thomas B. Holloway, Philadelphia.
Secretary—Albert E. Bulson, Jr., Fort Wayne, Ind.
Executive Committee—Walter R. Parker, Detroit; William Zentmayer, Philadelphia; Alexander Duane, New York.
(Stenographer—James C. Marriott, New York)

Wednesday, June 11—9 a. m.

Meeting Place—Traymore, Rose Room

1. Chairman's Address. Cassius D. Wescott, Chicago.

SYMPOSIUM ON REFRACTION

2. Ophthalmologist and Physician. Charles P. Emerson, Indianapolis.
3. Necessary but Often Neglected Refinements in the Examination of Ocular Refraction. Walter L. Pyle, Philadelphia.
4. The Present Status of Refraction Work. Edwin J. Gardiner, Chicago.
5. The Correction of the Muscular Anomalies of the Eye of Only Less Importance Than That of Their Faults of Refraction. Samuel Theobald, Baltimore.
   Discussion of the Symposium to be opened by Edward Jackson, Denver; Albert E. Bulson, Jr., Fort Wayne, Ind.; Thomas B. Holloway, Philadelphia, and Isaac Hartshorn, New York.

EXHIBITION OF NEW INSTRUMENTS AND APPLIANCES

Wednesday, June 11—2 p. m.

Meeting Place—Traymore, Rose Room

6. The Organization and Activities of the Ophthalmic Service in the American Expeditionary Forces. Allen Greenwood, Boston.
   Discussion to be opened by James Bordley, Jr., Baltimore.
7. The Control of Trachoma Among the Alien Labor Companies of the British and American Expeditionary Forces. George S. Derby, Boston.
   Discussion to be opened by Allen Greenwood, Boston.
8. Group Study, a Necessity in Ophthalmic Research. F. Park Lewis, Buffalo.
   Discussion to be opened by Walter R. Parker, Detroit.
9. Daylight Illumination of Interiors. Edward Jackson, Denver.
   Discussion to be opened by Nelson M. Black, Milwaukee.
10. Family Degeneration of the Macula Lutea. Robert Blue, Chicago.
    Discussion to be opened by William Zentmayer, Philadelphia.

Thursday, June 12—9 a. m.

Meeting Place—Traymore, Rose Room

Election of Officers

Reports of Committees

11. The Action of Radium on Cataracts. Martin Cohen and Isaac Levin, New York.
    Discussion to be opened by E. V. L. Brown, Chicago.
12. Immediate Capsulotomy in the Extraction of Senile Cataract. Arthur G. Bennett, Buffalo.
    Discussion to be opened by Harry W. Woodruff, Joliet.
13. Adventitious Hyaloid Membrane Following Operation for Secondary Cataract. S. Lewis Ziegler, Philadelphia.
    Discussion to be opened by Alexander Duane, New York.
14. The Autotoxic Factor in Sympathetic Ophthalmia. Arnold Knapp, New York.
    Discussion to be opened by Harold Gifford, Omaha.
15. Treatment of Symblepharon and Restoration of the Orbital Socket. William H. Wilder, Chicago.
    Discussion to be opened by John E. Weeks, New York.
16. The Rôle of Teeth, Tonsils, and Toxemias of the Intestinal Tract in Relation to Diseases of the Eye. George Huston Bell, New York.
    Discussion to be opened by Hiram Woods, Baltimore.

Friday, June 13—9 a. m.

Meeting Place—Traymore, Rose Room

17. A New Operation for the Relief of Conical Cornea. L. Webster Fox, Philadelphia.
    Discussion to be opened by Walter B. Lancaster, Boston.
18. Uveitis. A. Edward Davis, New York.
    Discussion to be opened by George E. de Schweinitz, Philadelphia.
19. (1) Cysticercus of the Vitreous; (2) Congenital Multilocular Cysts in Relation with the Retina, and (3) Anterior Lenticonus, Being a Clinical Communication. George E. de Schweinitz, Philadelphia, and Meyer Wiener, St. Louis.
    Discussion to be opened by Frederick H. Verhoeff, Boston.
20. Foreign Bodies Within the Eyeball. John O. McReynolds, Dallas, Texas.
    Discussion to be opened by William M. Sweet, Philadelphia.
21. The Treatment of Dacriocystitis by Curettage. John Green, Jr., St. Louis.
    Discussion to be opened by William R. Thompson, Fort Worth, Texas.
22. Personal Observations Regarding the Treatment of Glaucoma. John E. Weeks, New York.
    Discussion to be opened by William Campbell Posey, Philadelphia.

SECTION ON LARYNGOLOGY, OTOLOGY, AND RHINOLOGY

MEETS IN TRAYMORE, BELVIDERE—ALL MEETINGS

OFFICERS OF SECTION

Chairman—Lee Wallace Dean, Iowa City, Iowa.
Vice Chairman—Eugene R. Lewis, Dubuque, Iowa.
Secretary—William B. Chamberlin, Cleveland.
Executive Committee—Hill Hastings, Los Angeles; Francis P. Emerson, Boston; Greenfield Sluder, St. Louis.
(Stenographer—Miss F. E. Dillon, Indianapolis)

Wednesday, June 11—9 a. m.

Meeting Place—Traymore, Belvidere

1. Chairman's Address. Lee Wallace Dean, Iowa City, Iowa.
2. Physiologic Mechanism of Sneezing and Nasal Hydrorrhea. Albert P. Brubaker, Philadelphia.
   Discussion to be opened by Wolf Freudenthal, New York.
3. Nasal Hydrorrhea. John A. Thompson, Cincinnati.
   Discussion to be opened by H. Holbrook Curtis, New York.
4. Asthma as a Nasal Reflex. Greenfield Sluder, St. Louis.
   Discussion to be opened by Emil Mayer, New York, and Orville H. Brown, Phoenix, Ariz.
5. Results Obtained in the Treatment of Hay-Fever (Pollen Disease) by Pollen Extracts.. Karl K. Koessler, Chicago.
   Discussion to be opened by George E. Shambaugh, Chicago.
6. Sphenopalatine Ganglion Neurosis. Harry L. Pollock, Chicago.
   Discussion to be opened by William Mithoefer, Cincinnati.
7. The Accessory Sinuses in Children. Seymour Oppenheimer, New York.
   Discussion to be opened by Charles Gilmore Kerley, New York.

Thursday, June 12—9 a. m.

Meeting Place—Traymore, Belvidere

Election of Officers

EXHIBITION OF NEW INSTRUMENTS AND APPLIANCES

Report of Committees

8. Arachidic Bronchitis. Chevalier Jackson, Philadelphia.
   Discussion to be opened by Edwin E. Graham, Philadelphia.
9. Influenza Croup, Diagnosed by Direct Examination of the Larynx. Henry L. Lynah, New York.
   Discussion to be opened by Hubert Arrowsmith, Brooklyn.
10. Relation of the Ear and Accessory Sinuses to Influenza During the Recent Epidemic, as Observed at the Walter Reed General Hospital, Takoma Park, D. C. Joseph H. Bryan, Washington, D. C., and C. Norman Howard, Warsaw, Ind.
    Discussion to be opened by George Fetterolf, Philadelphia, and H. J. Nichols, Washington, D. C.
11. The Surgery of the Facial Nerve for Chronic Peripheral Facial Paralysis. William Sharpe, New York.
    Discussion to be opened by Philip D. Kerrison, New York, B. Alexander Randall and S. MacCuen Smith, Philadelphia.
12. Reconstruction of the Defects in Hearing and Speech, As Carried Out by the Division of Physical Reconstruction, Surgeon-General's Office. Charles W. Richardson, Washington, D. C.
    Discussion to be opened by John M. Ingersoll, Cleveland.
13. Some Observations on the Present Status of Oto-Laryngology in America. Thomas J. Harris, New York.
    Discussion to be opened by Harris P. Mosher, Boston, and James F. McKernon, New York.
14. Abscess of the Brain: Its Surgical Treatment. Wells P. Eagleton, Newark, N. J.
    Discussion to be opened by John W. Murphy, Cincinnati, and George F. Cott, Buffalo.

Friday, June 13—9 a. m.

Meeting Place—Traymore, Belvidere

15. Mastoidectomy: Postoperative Treatment by Carrel-Dakin Solution and Results. John B. Potts, Omaha.
    Discussion to be opened by Ewing W. Day, Pittsburgh, and Arthur C. Stokes, Omaha.
16. Some Experiences of a Commanding Officer of a Base Hospital in France. Ross Hall Skillern, Philadelphia.
    Discussion to be opened by George M. Coates, Philadelphia.
17. Tranquil Tracheotomy by Injecting Cocain Within the Windpipe.
    Sir St. Clair Thompson (Guest of Honor), London, England.
    General Discussion.
18. Film: Fit to Fly. Air Service, Medical Corps, U. S. Army.

SECTION ON DISEASES OF CHILDREN

MEETS IN ST. PAUL'S CHURCH, CHAPEL—ALL MEETINGS

OFFICERS OF SECTION

Chairman—Frank P. Gengenbach, Denver.
Vice Chairman—Jay I. Durand, Seattle.
Secretary—E. C. Fleischner, San Francisco.
Executive Committee—T. C. McCleave, Oakland, Calif; J. P. Sedgwick, Minneapolis; Laurence R. DeBuys, New Orleans.
(Stenographer—Mr. Willard Bottome, New York)

Wednesday, June 11—2 p. m.

Meeting Place—St. Paul's Church, Chapel

1. Chairman's Address: Our Section in War Work. Franklin P. Gengenbach, Denver.
2. Report of the Advisory War Committee of the Children's Section. Julius P. Sedgwick, Minneapolis.
3. Results of Children's Year. Anna E. Rude, Washington, D. C.
4. The Work of the Pediatrist at Home. Frank C. Neff, Kansas City, Mo.
5. The Work of the Children's Bureau of the American Red Cross in Lyons, France. Clifford G. Grulee, Chicago.
6. The Artificial Feeding of Athreptic Infants. W. McKim Marriott, St. Louis.
7. The Deleterious Effect of Alkalinization of Infants' Food. Alfred F. Hess, New York.

Thursday, June 12—9 a. m.

Meeting Place—St. Paul's Church, Chapel

Election of Officers

8. Hemangio-Endotheliosarcoma of the Liver: A Disease of Early Life. John A. Foote, Washington, D. C.
9. Observations on the Spinal Fluid of Acute Disease. William W. Herrick, New York, and Arthur M. Dannenberg, Philadelphia.
10. Quantitative and Qualitative Changes in Cerebrospinal Fluid and Their Significance. Abraham Levinson, Chicago.
11. Pneumonia in Infancy and Childhood Without Physical Signs. Rowland G. Freeman, New York.
12. A Comparative Study of the Early and Late Secondary Complications of Influenzal Pneumonia in the Army and Those of Civil Pediatric Practice. Julius H. Hess, Chicago.
13. Abscess of the Lung in Children. Harry Wessler and Herman Schwartz, New York.
14. Some Practical Experiences in the Treatment of Children with Tuberculosis. R. Cole Newton, Montclair.

Friday, June 13—2 p. m.

Meeting Place—St. Paul's Church, Chapel

15. New Methods in Outpatient Work. Charles Hendee Smith, New York.
16. The Analysis of Human Milk: The Technic of Obtaining Samples and the Interpretation of Results. Fritz B. Talbot, Boston.
17. Retrospect of Fifteen Years' Experience in the Treatment of Hypertrophic Pyloric Obstruction in Infants. Langley Porter, San Francisco.
18. Chemical Examination of the Blood of Children. Henry D. Chapin, New York.
19. The Abuse of Cathartics and Laxatives in Infancy and Childhood. Louis Fischer, New York.
20. The Nervous Child and His Management. Edwin B. McCready, Pittsburgh.
21. A Study in a Foundling Institution to Determine the Existence of Congenital Lues. Laurence R. DeBuys, New Orleans.

SECTION ON PHARMACOLOGY AND THERAPEUTICS

MEETS, WEDNESDAY AND THURSDAY, IN ST. PAUL'S CHURCH, LECTURE ROOM; *FRIDAY, IN ST. PAUL'S CHURCH, AUDITORIUM*

OFFICERS OF SECTION

Chairman—W. A. Bastedo, New York.
Vice Chairman—G. W. McCoy, Washington, D. C.
Secretary—Cary Eggleston, New York.
Executive Committee—J. F. Anderson, New Brunswick, N. J.; R. A. Hatcher, New York; Albion W. Hewlett, San Francisco; Arthur D. Hirschfelder, Minneapolis.

(Stenographer—Mr. Rexford L. Holmes, Washington, D. C.)

Wednesday, June 11—2 p. m.

Meeting Place—St. Paul's Church, Lecture Room

1. Chairman's Address: Suggestions for an Ideal Course in Therapeutics. Walter A. Bastedo, New York.
2. Therapeutic Aspect of Blood Transfusion. Lester J. Unger, New York.
3. Critical Period in Various Diseases Treated by Blood Transfusion. Edward Lindeman, New York.
4. The Action of Anthracene Cathartics on the Isolated Uterus. Charles C. Lieb, New York.
5. Therapeutic Observations in Bacillary Dysentery. P. Nolf, Brussels, Belgium. (By Invitation).
6. The Therapeutic Use of Active Deposit of Radium. Henry H. Janeway, New York.
7. A Study of Acute Bichlorid Intoxication in Normal and in Naturally Nephropathic Dogs. William deB. MacNider, Chapel Hill, N. C.

Thursday, June 12—9 a. m.

Meeting Place—St. Paul's Church, Lecture Room

Election of Officers

8. Forty Years' Observation Among Beer, Wine and Whisky Drinkers. Lambert Ott, Philadelphia.
9. Chronic Alcoholism: Dangers of Immediate Withdrawal. George E. Pettey, Memphis, Tenn.
10. A Contribution to the Pharmacology of the Local Anesthetics. Cary Eggleston and Robert A. Hatcher, New York.
11. The Principles of the Treatment of Asthma. Orville Harry Brown, Phoenix, Ariz.
12. Allergy in Drug Idiosyncrasy. Robert A. Cook, New York.
13. Results in the Modern Treatment of Diabetes. Henry Rawle Geyelin, New York.
14. A Therapeutic Study of Benzyl Benboate: Pharmacologic and Clinical. David I. Macht, Baltimore.

Friday, June 13—2 p. m.

Meeting Place—St. Paul's Church, Auditorium

JOINT MEETING OF SECTIONS ON PREVENTIVE MEDICINE AND PUBLIC HEALTH; PHARMACOLOGY AND THERAPEUTICS AND PATHOLOGY AND PHYSIOLOGY

SYMPOSIUM ON INFLUENZA

15. Experiments on Volunteers to Determine the Mode of Spread of Influenza. Milton J. Rosenau, Boston.
16. Epidemiology of Influenza. Wade H. Frost, Washington, D. C.
17. The Bacteriology of Influenza and Its Complications. William H. Park, New York.
18. The Pathology of Influenza. William G. MacCallum, Baltimore.
19. The Symptoms and Complications of Influenza. Lewis A. Conner, New York.
20. Further Studies on Prophylactic Inoculation in Influenza and Pneumonia. Edward C. Rosenow, Rochester, Minn.
21. Present Status of Prophylactic Vaccination Against Influenza. George W. McCoy, Washington, D. C.
22. Value of Convalescent Blood and Serum in the Treatment of Influenzal Pneumonia. Henry F. Stoll, Hartford, Conn.
23. The Treatment of Influenza by Means Other Than Vaccine and Serums. James B. Herrick, Chicago.

SECTION ON PATHOLOGY AND PHYSIOLOGY

MEETS, WEDNESDAY AND THURSDAY, IN ROYAL PALACE, HALL A; *FRIDAY, IN ST. PAUL'S CHURCH, AUDITORIUM*

OFFICERS OF SECTION

Chairman—Francis Carter Wood, New York.
Vice Chairman—Isabella C. Herb, Chicago.
Secretary—Josiah J. Moore, Chicago.
Executive Committee—F. P. Gay, Berkeley, Calif.; James Ewing, New York; Louis B. Wilson, Rochester, Minn.

(Stenographer—Mr. George B. Cock, Philadelphia)

Wednesday, June 11—2 p. m.

Meeting Place—Royal Palace, Hall A

1. Chairman's Address: The Relation of Pathology to Practice. Francis Carter Wood, New York.
2. The Human Machine in the Factory. Frederic Lee, New York.
3. Clinical Types of Occupational Diseases and the Study of Methods for their Prevention. Louis I. Harris, New York.
4. A Newly Recognized Cause of Pulmonary Disease—*Ascaris lumbricoides.* B. H. Ransom, Washington, D. C.
5. The Periodicity of Microfilaria. Kenneth M. Lynch, Charleston, S. C.
6. Experimental Emphysema. Sarah R. Kelman, Iowa City, Iowa.

Thursday, June 12—9 a. m.

Meeting Place—Royal Palace, Hall A

Election of Officers

7. Mustard Gas. Eli K. Marshall, Jr., Washington, D. C.
8. Mustard Gas: Its Penetration and Mode of Function in the Tissues. G. H. A. Clowes, Indianapolis.
9. The Physiology and Experimental Treatment of Acute Poisoning with the Lethal War Gases. Frank P. Underhill, New Haven, Conn.
10. Anatomic Changes in the Respiratory Tract Initiated by Irritating Gases. Milton C. Winternitz, New Haven, Conn.
11. Duodenectomy: A Preliminary Report. Frank C. Mann and K. Kawamura, Rochester, Minn.
12. Clinical Diagnosis as Compared with Necropsy Findings in Six Hundred Cases. Howard T. Karsner, L. Rothschild and E. C. Crump, Cleveland.

Friday, June 13—2 p. m.

Meeting Place—St. Paul's Church, Auditorium

JOINT MEETING WITH THE SECTIONS ON PHARMACOLOGY AND THERAPEUTICS, AND PREVENTIVE MEDICINE AND PUBLIC HEALTH

SYMPOSIUM ON INFLUENZA

For program see page 1418

SECTION ON STOMATOLOGY

MEETS IN ROYAL PALACE, HALL B—ALL MEETINGS

OFFICERS OF SECTION

Chairman—E. S. Talbot, Chicago.
Vice Chairman—Chalmers J. Lyons, Ann Arbor, Mich.
Secretary—Arthur D. Black, Chicago.
Executive Committee—Frederick B. Moorehead, Chicago; Arthur D. Black, Chicago; Frederick B. Noyes, Chicago.

(Stenographer—Mr. William F. Smart, New York)

Wednesday, June 11—9 a. m.

Meeting Place—Royal Palace, Hall B

1. Chairman's Address. Eugene S. Talbot, Chicago.
2. Macrocheilia, with Report of Two Cases. (Lantern Demonstration). F. B. Moorehead, Chicago.
3. Teaching the Principles of Maxillofacial Surgery in a Civilian School. Charles R. Turner, Philadelphia.
4. Teaching the Principles of Maxillofacial Surgery in a Military School. G. V. I. Brown, Milwaukee.
5. Experience of a Dental Surgeon in an Evacuation Hospital. Rae P. McGee, Denver.
6. Experience of a Dental Surgeon in a Base Hospital in the Advanced Area. Ivan Smith, Mishawaka, Ind.

Thursday, June 12—9 a. m.

Meeting Place—Royal Palace, Hall B

Election of Officers

7. Experience of a Dental Surgeon in a Base Hospital in a Base Section. Stewart Ruggles, Portsmouth, Ohio.
8. Experience of an Area Consultant in the Zone of the Advance. George W. Schaeffer, Columbus, Ohio.
9. Experience of an Area Consultant in a Base Section. Justin M. Waugh, Hood River, Ore.
10. Experience of an Area Consultant in the Intermediate Section. Herbert A. Potts, Chicago.
11. Observations on the Work at Queens Hospital in England. George M. Dorrance, Philadelphia.
12. Reconstruction Work in War Injuries of the Jaws (Lantern Demonstration). Robert H. Ivy, Milwaukee, and Joseph D. Eby, Washington, D. C.

Friday, June 13—9 a. m.

Meeting Place—Royal Palace, Hall B

13. Bone Grafting in Jaw Cases. Frank J. Tainter, St. Charles, Mo.
14. Infected Fractures of the Mandible. Daniel H. Macauly, Jr., and Ernest P. Dameron, Cape May, N. J.
15. Osteoperiosteal Bone Grafts of the Mandible as Performed by the French; A Report of Two Recent Cases. Henry S. Dunning, New York.
16. Prosthetic Appliances in Relation to the Surgical Treatment of Wounds of the Face and Jaws. V. H. Kazanjian, Boston.
17. Jaw Service at the American Red Cross Hospital No. 1, Paris. William Coughlin, St. Louis.

General discussion of Oral Surgery Service in the War will be opened by Vilray P. Blair, St. Louis.

SECTION ON NERVOUS AND MENTAL DISEASES

MEETS IN BRIGHTON CASINO—ALL MEETINGS

OFFICERS OF SECTION

Chairman—Archibald Church, Chicago.
Vice Chairman—E. E. Southard, Boston.
Secretary—Charles W. Hitchcock, Detroit.
Executive Committee—Francis X. Dercum, Philadelphia; Bernard Sachs, New York; C. Eugene Riggs, St. Paul.

(Stenographer—Miss Edith Phelps, New York)

Wednesday, June 11—2 p. m.

Meeting Place—Brighton, Casino

1. Chairman's Address: The Pathology of Cervical Ribs. Archibald Church, Chicago.
2. The Mechanism of Referred Pain, Hyperalgesia and Alcoholic Injections for the Relief of Neuralgia with Suggestions for the Surgical Treatment of Injured Nerves. Joseph Byrne, New York.
   Discussion to be opened by Alfred S. Taylor and Israel Strauss, New York.
3. Some Fundamental Traits of the So-Called Neurotic. Meyer Solomon, Chicago.
4. A New Polyglandular Compensatory Syndrome. Walter Timme, New York.
5. Treatment of War Neurosis. Theodore H. Weisenburg, Philadelphia.
6. The Psychopathology of Amnesia. Edward E. Mayer, Pittsburgh.
7. The Management of War Hysteria. Tom A. Williams, Washington, D. C.

Thursday, June 12—9 a. m.

Meeting Place—Brighton, Casino

Election of Officers

8. Neurologic and Psychiatric Experiences Illustrative of Real Progress and of Fads and Fallacies in Therapeutics. Charles K. Mills, Philadelphia.
9. The Range of the General Practitioner in Psychiatry. Elmer E. Southard, Boston.
10. Congenital Tumor (Telangiectasis) and Associated Cerebral Movements. William G. Spiller, Philadelphia.
11. Original Test for the Pathologic Great Toe Sign with Illustrative Cases. Leo M. Crafts, Minneapolis.
12. Clinical Report of a Case of Tumor of the Pons Varolii (Lantern Demonstration). Tom B. Throckmorton, Des Moines, Iowa.
13. The Histologic Changes in the Brain in Lethargic Encephalitis (Lantern Demonstration). Peter Bassoe and George B. Hassin, Chicago.
14. The Rôle of the Pituitary Gland in Epilepsy. Beverly Tucker, Richmond, Va.
    Discussion to be opened by Walter Timme, New York, and Lewellys F. Barker, Baltimore.

Friday, June 13—2 p. m.

Meeting Place—Brighton, Casino

15. Lethargic Encephalitis. Andrew C. Gillis, Baltimore.
16. A Case of Hysterical Hemiplegia, Following a Shrapnel Wound of Scalp, and Presenting Interesting Clinical Features. Harry H. Drysdale, Cleveland.

17. The Therapy of Neurosyphilis, *Judged by Arsenic Penetration of the Meninges.*
Henry G. Mehrtens, San Francisco.
18. Multiple Neuritis of Toxi-Infectious Origin with Especial Reference to Diabetic Polyneuritis.
Alfred Gordon, Philadelphia.
19. The Resemblance of the Sensory Symptoms of Diphtheritic Multiple Neuritis to Those of Anemic Cord Changes. George Wilson, Philadelphia.
20. Nervous System Sequelae in Three-Day Fever.
William H. Robey, Jr., Boston.

SECTION ON DERMATOLOGY

MEETS, WEDNESDAY AND FRIDAY, IN TRAYMORE, BELVIDERE; THURSDAY, IN SEASIDE

OFFICERS OF SECTION

Chairman—Otto H. Foerster, Milwaukee.
Vice Chairman—David Lieberthal, Chicago.
Secretary—Walter J. Highman, New York.
Executive Committee—Howard Morrow, San Francisco; Henry R. Varney, Detroit; Henry H. Hazen, Washington, D. C.
(Stenographer—Mrs. Irene Hilton Snyder, Chicago)

Wednesday, June 11—2 p. m.

Meeting Place—Traymore, Belvidere

1. *Chairman's Address: Dermatology and Associated Disorders of the Mucous Membranes.*
Otto H. Foerster, Milwaukee.

SYMPOSIUM ON DERMATOLOGY AND SYPHILOLOGY DURING THE WAR

2. Dermatology and Syphilology in a Medical Advisory Board. Henry H. Hazen, Washington, D. C.
3. Dermatology and Syphilology in the Army.
Warren Walker, Philadelphia.
4. Experiences with Scabies at a Debarkation Port.
C. Guy Lane, Woburn, Mass.
5. Responsibilities in the Treatment of Syphilis.
Harry G. Irvine, Minneapolis.
6. A State Campaign Against Venereal Diseases.
Harold N. Cole, Cleveland.

Thursday, June 12—9 a. m.

Meeting Place—Seaside

Election of Officers

SYMPOSIUM ON SYPHILOLOGY

7. Further Work with Arsphenamin.
Jay F. Schamberg, John A. Kolmer and G. W. Raiziss, Philadelphia.
8. Vitiligo and Syphilis.
John E. Lane, New Haven, Conn.
9. Observations on the Treatment of Syphilis.
William H. Guy, Pittsburgh.
10. Syphilitic Epididymitis.
Henry E. Michelson, Minneapolis.
11. Two Years of Radium.
Howard Morrow, San Francisco.
12. Roentgen-Ray Treatment of Widespread and Generalized Skin Diseases. Fred Wise, New York.
13. Treatment of Nevus Vasculosis and Other Skin Defects by the Electrodesiccation Method, Ultraviolet Rays, Radium and Electrolysis.
William L. Clark, Philadelphia.

Friday, June 13—2 p. m.

Meeting Place—Traymore, Belvidere

14. Ragweed Dermatitis.
Richard L. Sutton, Kansas City, Mo.
15. Importance of Normal Amount of Oil in the Skin.
Henry R. Varney, Detroit.
16. The *Moulage* as a Record Employed at the Army Medical Museum. J. Frank Wallis, Pleasantville, N. J.
17. Blood Sugar Findings in Diseases of the Skin.
Isaac R. Pels, Baltimore.

Allen W. Freeman, Columbus, Ohio.
4. What New Jersey Has Done in Mosquito Extermination.
William E. Darnall, Atlantic City, N. J.
5. Recent and Pending National Legislation Affecting Public Health Control.
Leslie L. Lumsden, Washington, D. C.
6. The Demand *During the Reconstruction* Period for a Community Nursing Service.
Bertis R. Wakeman, Hornell, N. Y.

Thursday, June 12—9 a. m.

Meeting Place—Breakers, Egyptian Room

Election of Officers

7. General Health Activities and Their Influence on Tuberculosis Mortality.
George Thomas Palmer, Springfield, Ill.
8. The Aftermath of Influenza.
Franklin C. Gram, Buffalo.
9. Some Practical Statistics of Influenza Morbidity and Mortality. Frederick L. Hoffman, Newark, N. J.
10. Progress of Venereal Disease Control.
C. C. Pierce, Washington, D. C.
11. Encephalitis Lethargica. Josephine B. Neal, New York.
12. Open Air Classes. Leopold Marcus, New York.

Friday, June 13—2 p. m.

Meeting Place—St. Paul's Church, Auditorium

JOINT MEETING OF SECTIONS ON PREVENTIVE MEDICINE AND PUBLIC HEALTH; PHARMACOLOGY AND THERAPEUTICS, AND PATHOLOGY AND PHYSIOLOGY

SYMPOSIUM ON INFLUENZA

For program see page 1418

SECTION ON GENITO-URINARY DISEASES

MEETS, WEDNESDAY AND FRIDAY, IN BRIGHTON, CASINO; THURSDAY, IN ALAMAC

OFFICERS OF SECTION

Chairman, W. F. Braasch, Rochester, Minn.
Vice Chairman, R. L. Rigdon, San Francisco.
Secretary—E. O. Smith, Cincinnati.
Executive Committee—Louis E. Schmidt, *Chicago;* Hugh Cabot, Boston; Edward L. Keyes, Jr., New York.
(Stenographer—Mr. George D. Ziegler, New Brunswick, N. J.)

Wednesday, June 11—9 a. m.

Meeting Place—Brighton, Casino

1. The Colliculus Seminalis at Birth: With a Report of the Origin, Development, and Zonal Distribution of Its Gland Tubules. Ernest M. Watson, Buffalo. Discussion to be opened by Anton G. Rytina, Baltimore.
2. Recent *Considerations* Concerning the Seminal Vesicles with Special References to Differential Diagnosis and Treatment. Edward W. White, Chicago. Discussion to be opened by Louis E. Schmidt, Chicago.
3. Further Observations On the Use of Indigo-Carmin as a Test of Renal Function.
H. Dawson Furniss, New York.
Discussion to be opened by Benjamin A. Thomas, Philadelphia, and Leo Buerger, New York.

4. Relief of Essential Hematuria by Intrapelvic Injections of Silver Nitrate. Anton G. Rytina, Baltimore.
   Discussion to be opened by Herman L. Kretschmer, Chicago.
5. Urethral Strictures: Their Nonoperative Treatment for the General Practitioner. Wirt B. Dakin, Los Angeles.
   Discussion to be opened by William N. Wishard, Indianapolis.
6. Malakoplakia of the Bladder: Reports of Two Cases. Alfred I. Folsom, Dallas, Texas.
   Discussion to be opened by Arthur L. Chute, Boston.
7. Etiology of Vesical Diverticulum. Frank Hinman, San Francisco.
   Discussion to be opened by Charles M. McKenna, Chicago.
8. Contracture of the Neck of the Bladder: Its Pathology and Operative Treatment. Leo Buerger, New York.
   Discussion to be opened by Hugh H. Young, Baltimore, and William C. Quinby, Boston.

Thursday, June 12—9 a. m.

Election of Officers

Meeting Place—Alamac

9. Chairman's Address: Ureteral Dilatation. William F. Braasch, Rochester, Minn.
   Discussion to be opened by Guy L. Hunner, Baltimore.
10. Urologic Findings in Diseases of the Central Nervous System. John R. Caulk, Harry G. Greditzer and Francis M. Barnes, Jr., St. Louis.
11. Report on Shell Fractures of Spine, Studied at Walter Reed General Hospital with Observations on Changes in Kidney and Bladder Function. Harry W. Plaggemeyer, Detroit.
    Discussion to be opened by Edward L. Keyes, New York; John T. Geraghty, Baltimore, and Irving S. Koll, Chicago.
12. Ureteral Transplantation in Inoperable Conditions of the Bladder. William E. Lower, Cleveland.
    Discussion to be opened by Edwin Beer, New York.
13. Hematogenous Infections of the Kidney. William J. Mayo, Rochester, Minn.
    Discussion to be opened by Hugh H. Young, Baltimore.
14. Clinical Observations in the Treatment of Nephrolithiasis. Albert J. Ochsner, Chicago.
    Discussion to be opened by H. G. Bugbee, New York.
15. Department of Urology, American Expeditionary Forces. Hugh H. Young, Baltimore.
    Discussion to be opened by Hugh Cabot, Boston.

Friday, June 13—9 a. m.

Meeting Place—Brighton, Casino

16. Some Problems in Urology in the United States Navy. (Lantern Demonstration.) Oswald S. Lowsley, New York.
17. The Army School of Urology. Gideon Timberlake, Baltimore.
18. The Civilian Venereal Disease Dispensary as a War Measure. (Being a report of the work done at the Illinois Social Hygiene League Dispensary, during and since the war). Budd C. Corbus, Chicago.
    Discussion to be opened by Francis R. Hagner, Washington, D. C.; William L. Baum, Chicago, and Harry E. Kleinschmidt, Washington, D. C.
19. The Early Diagnosis and a Comparative Standardization of the Treatment of Syphilis. Elmore B. Tauber, Cincinnati.
    Discussion to be opened by Abraham L. Wolbarsh, New York.
20. Some Urologic Aspects of Dermoid Cysts. William C. Quimby, Boston.
21. The Frequency and Significance of Granular Urethritis. Noah E. Aronstam, Detroit.
    Discussion to be opened by Frederick W. Robbins, Detroit.

21. Congenital Peno-Rectal Fistula. Simon Englander, Cleveland.

SECTION ON ORTHOPEDIC SURGERY

MEETS IN CHALFONTE, ROOM 17—ALL MEETINGS

OFFICERS OF SECTION

Chairman—Emil S. Geist, Minneapolis.
Vice Chairman—Benjamin P. Farrell, New York.
Secretary—Henry B. Thomas, Chicago.
Executive Committee—Russell A. Hibbs, New York; Edwin W. Ryerson, Chicago; Albert H. Freiberg, Cincinnati.
(Stenographer—Miss Lulu Gay, Philadelphia)

Wednesday, June 11—9 a. m.

Meeting Place—Chalfonte, Room 17

1. Intramedullary Beef-Bone Splints in Fractures of Long Bones: New Technic of Application. (Lantern Demonstration). Edwin W. Ryerson, Chicago.
   Discussion to be opened by Ralph R. Fitch, Rochester, N. Y., and Frank E. Peckham, Providence, R. I.
2. Osteomyelitis (Lantern Demonstration). James W. Sever, Boston.
   Opening discussion by Pedro Chutro, Buenos Aires, Albert H. Freiberg, Cincinnati; Robert B. Osgood, Boston, and William S. Baer, Baltimore.
3. Surgical Treatment and After-Care of Old Unreduced Pott's Fractures (Lantern Demonstration). William L. Sneed, New York.
   Discussion to be opened by George W. Hawley, Bridgeport, Conn.; Frederick J. Cotton, Boston, and Zabdiel B. Adams, Boston.
4. The Reconstruction of a Loss of Substance of the Humerus Following Shell Injury to Upper Arm: Report of Case. Charles L. Scudder, Boston.
5. Place of Special Work in the Army During the Emergency. Elliott G. Brackett, Boston.
   Discussion to be opened by Sir Gen. Robert Jones, Liverpool, England.
6. Secondary Treatment of War Amputés. Carl C. Yount, New York.
   Discussion to be opened by Sir Gen. Robert Jones, Liverpool, England.
7. Amputation Stumps in Relation to the Fitting of Artificial Limbs. E. J. Rose, Gallipolis, Ohio.
   Discussion to be opened by David Silver, Washington, D. C.; Philip D. Wilson, Columbus, Ohio; W. S. Baer, Baltimore, and John S. Davis, Dallas, Texas.

Thursday, June 12—9 a. m.

Meeting Place—Chalfonte, Room 17

Election of Officers

8. Improvised Orthopedic Exercising Apparatus. Rudolph S. Reich, Cleveland.
   Discussion to be opened by W. G. Stern, Cleveland.
9. The Foot Problem in the Army. William C. Peters, Bangor, Me.
   Discussion to be opened by E. W. Ryerson, Chicago.
10. An Operation for Claw Foot (Lantern Demonstration). Russell A. Hibbs, New York.
    Discussion to be opened by Fred J. Fassett, Seattle, Benjamin P. Farrell, New York, and Michael Hoke, Atlanta, Ga.
11. Chairman's Address: Some of the Things that Orthopedic Surgery has Done for the War and that the War has Done for Orthopedic Surgery. Emil S. Geist, Minneapolis.
12. Early Functional Results After Secondary Suture. Base Hospital No. 9, France (Lantern Demonstration). George W. Hawley, New York.
    Discussion to be opened by Col. H. W. Gray, London, England, and William W. Plummer, Buffalo.
13. Precombat Orthopedic Work in the United States. James T. Rugh, Philadelphia.
    Discussion to be opened by Emil S. Geist, Minneapolis, and Brainerd H. Whitbeck, New York.
14. Precombat Orthopedic Work Overseas. Henry P. Mauck, Baltimore.
    Discussion by Z. B. Adams, Boston; Robert J. Graves, Concord, N. H., and Eben W. Fiske, Boston.
15. The Standardized Splints and Methods of Treatment in Bone and Joint Injury, A. E. F. Joel E. Goldthwait, Boston.
    Discussion to be opened by Sir Gen. Robert Jones, Liverpool, England; William W. Plummer, Buffalo, and Wallace Cole, St. Paul.

Friday, June 13—9 a. m.

Meeting Place—Chalfonte, Room 17

16. The Orthopedic Surgeon and Industrial Accidents.
LEO B. MEYER, New York.
Discussion to be opened by JOHN C. A. GERSTER, New York, and STERLING BUNNELL, San Francisco.

17. The Curative Work Shop. JAMES C. GRAVES, JR.
Discussion to be opened by ELLIOTT G. BRACKETT, Boston; ZABDIEL B. ADAMS, Boston, and NATHANIEL ALLISON, St. Louis.

racture of the Neck of the Femur: An Analysis of One Hundred Cases. WILLIS C. CAMPBELL, Memphis, Tenn.
Discussion to be opened by ELLIOTT G. BRACKETT, Washington, D. C.

9. Ununited Fractures of the Hip.
MELVIN S. HENDERSON, Rochester, Minn.
Discussion to be opened by ELLIS W. JONES, Los Angeles, and WALLACE BLANCHARD, Chicago.
Discussion to be opened by ARTHUR J. GILLETTE, St. Paul, and JOHN S. DAVIS, Dallas, Texas.

20. Indications for Surgical Intervention in Peripheral Nerve Injuries (Lantern Demonstration).
KARL W. NEY, New Orleans.
Discussion to be opened by COL. H. M. GRAY, London, England; EMILE ALTMAN, New York; SAMUEL C. BALDWIN, Salt Lake City, and HARRY A. HALGREN, Watertown, Wis.

21. Operative Treatment of Peripheral Nerve Injuries.
CHARLES A. ELSBERG, New York.
Discussion to be opened by PEDRO CHUTRO, Embarkation Hospital No. 4; Frederick C. KIDNER, Detroit, and SAMUEL W. BOORSTEIN, New York.

22. Postoperative Treatment of Peripheral Nerve Injuries.
MURRAY S. DANFORTH, Providence, R. I.
Discussion to be opened by CHARLES H. FRAZIER, Philadelphia; PAUL F. STOOKEY, Lamont, Iowa; J. FRANK CORBETT, Minneapolis; WILLIAM W. PLUMMER, Buffalo, and DEAN D. LEWIS, Chicago.

SECTION ON GASTRO-ENTEROLOGY AND PROCTOLOGY

MEETS IN CHALFONTE, ROOM 16—ALL MEETINGS

OFFICERS OF SECTION

Chairman—WILLIAM M. BEACH, Pittsburgh.
Vice Chairman—FRANK SMITHIES, Chicago.
Secretary—HORACE W. SOPER, St. Louis.
Executive Committee—CHARLES G. STOCKTON, Buffalo; DWIGHT H. MURRAY, Syracuse, N. Y.; ANTHONY BASSLER, New York.

(Stenographer—Mr. JEROME VICTORY, Jersey City, N. J.)

Wednesday, June 11—9 a. m.

Meeting Place—Chalfonte, Room 16

1. Chairman's Address: Spirit of the Physician in War and Peace. WILLIAM M. BEACH, Pittsburgh.

2. Constipation: A New Definition, the Primary Causes and Its Hygienic Treatment.
DWIGHT H. MURRAY, Syracuse, N. Y.
Discussion to be opened by WILLIAM H. AXTELL, Bellingham, Wash.; ROLLA CAMDEN, Parkersburgh, W. Va.; J. M. FRICK, Toledo, Ohio, and V. LEE FITZGERALD, Providence, R. I.

3. Sphincter Inhibition as a Cause of Constipation and Other Gastro-Intestinal Disturbances.
JEROME M. LYNCH, New York.
Discussion to be opened by JOSEPH C. BLOODGOOD, Baltimore; J. COLES BRICK, Philadelphia; RALPH W. JACKSON, Fall River, Mass., and JAMES A. MACMILLAN, Detroit.

4. Proctology in a War Hospital.
LOUIS J. HIRSCHMAN, Detroit.
Discussion to be opened by GRANVILLE S. HANES, Louisville, Ky.; ALOIS B. GRAHAM, Indianapolis; D. C. MCKENNEY, Buffalo, and ARTHUR HEBB, Baltimore.

5. Late Syphilis Within the Rectum.
CHARLES J. DRUECK, Chicago.
Discussion to be opened by JOHN L. JELKS, Memphis,
H. Los Angeles; G. M. LINTHICUM,
H. STAUFFER, St. Louis.

6. Stricture of the Rectum. FRANK C. YEOMANS, New York.
Discussion to be opened by HOLLAND H. DONALDSON, Pittsburgh; CHARLES S. GILMAN, Boston; ROBERT T. MORRIS, New York, and J. RAWSON PENNINGTON, Chicago.

7. Examination of the Patient.
J. RAWSON PENNINGTON, Chicago.
Discussion to be opened by LEWIS H. ADLER, JR., Philadelphia; GEORGE B. EVANS, Dayton, Ohio; DONLEY C. HAWLEY, Burlington, Vt.; JAMES A. MCVEIGH, Detroit, and LOUIS J. KROUSE, Cincinnati.

Thursday, June 12—9 a. m.

Meeting Place—Chalfonte, Room 16

Election of Officers

8. Gastric Cell Primary Atrophy.
ANTHONY BASSLER, New York.
Discussion to be opened by MAX EINHORN, New York, and FRANK SMITHIES, Chicago.

9. Further Observations on the Gastro-Intestinal Disturbances Met with in Pernicious Anemia.
JULIUS FRIEDENWALD and THEODORE H. MORRISON, Baltimore.
Discussion to be opened by ARTHUR F. CHACE, New York, and MARTIN E. REHFUSS, Philadelphia.

10. The Metabolic Gradient Underlying Peristalsis.
WALTER C. ALVAREZ, San Francisco.
Discussion to be opened by JACOB KAUFFMANN, New York, and WALTER B. CANNON, Boston.

11. The Late Results of Supposedly Successful Operations on the Digestive Tract.
THOMAS R. BROWN, Baltimore.
Discussion to be opened by JOHN A. LICHTY, Pittsburgh, and WILLY MEYER, New York.

12. Certain Limitations of Roentgen-Ray Diagnosis of Gastro-Intestinal Diseases. DUDLEY ROBERTS, Brooklyn.
Discussion to be opened by GEORGE E. PFAHLER, Philadelphia, and JAMES T. CASE, Battle Creek, Mich.

13. The Operability of Cancer of the Stomach as Determined by the Roentgen Ray.
RUSSELL D. CARMAN, Rochester, Minn.
Discussion to be opened by R. WALTER MILLS, St. Louis, and LEWIS GREGORY COLE, New York.

Friday, June 13—9 a. m.

Meeting Place—Chalfonte, Room 16

14. Further Experiences with the String Test.
MAX EINHORN, New York.
Discussion to be opened by WILLIAM GERRY MORGAN, Washington, D. C., and ALLEN A. JONES, Buffalo.

15. The Importance of Detecting the Encysted Forms of the Parasitic Protozoa in the Feces.
SIDNEY K. SIMON, New Orleans.
Discussion to be opened by ALBERT BERNHEIM, Philadelphia.

16. The Prevalence of Amoeba, *Cercomonas Intestinalis Hominis*, and Pellagrous Infection in the South. The Responsibility for Which Rests on Nation and State. Suggestions as to Means of Control.
JOHN J. JELKS, Memphis, Tenn.
Discussion to be opened by JAMES C. JOHNSON, Atlanta, Ga.; SIDNEY K. SIMON, New Orleans.

17. Common Bile Duct Obstruction: Its Incidence and Clinical Recognition. FRANK SMITHIES, Chicago.
Discussion to be opened by DAVID RIESMAN, Philadelphia, and JOHN M. T. FINNEY, Baltimore.

18. Influence of Endocrine Functioning on Gastric-Intestinal Conditions. CLEMENT R. JONES, Pittsburgh.
Discussion to be opened by GEDIDE A. FRIEDMAN, New York, and JOHN C. HEMMETER, Baltimore.

19. Progress in Gastro-Enterology During the World War.
SEALE HARRIS, Birmingham, Ala.
Discussion to be opened by LOUIS M. GOMPERTZ, New Haven, Conn., and GEORGE B. EUSTERMAN, Rochester, Minn.

20. The Gastric Hypermotility Associated with Diseases of the Gallbladder, Duodenum and Appendix: A Clinical and Experimental Study.
GEORGE DAVID STEWART and WILLIAM HOWARD BARBER, New York.
Discussion to be opened by ANTHONY BASSLER, New York, and R. WALTER MILLS, St. Louis.

ATTRACTIONS AT THE EXHIBITION

The successful practice of medicine and surgery today depends on many different factors. Not the least of these is the service rendered by the manufacturers of medical and surgical supplies. What science conceives, these men execute. Like the faithful attendant in the operating room, they place in the physicians' hands those instruments, pharmaceuticals, appliances, supplies, textbooks, etc., needed in doing good, conscientious work and in following the latest technic in the treatment of disease.

At the Commercial Exhibit this year one may see at their best the fruits of the medical and surgical manufacturing industry. The military hospital has

FLOOR PLAN OF BALL ROOM BALCONY.

acted as a crucible out of which has come much that is new and better in diagnosis, treatment and surgery. The latter, in turn, have been responsible for the development of new appliances, new instruments, new remedies, new literature, etc. The bringing together into one unified exposition of more than a hundred exhibitors gives the physician a wonderful opportunity to see at first hand many of these new improvements as well as the best in those standard supplies which he uses every day.

Although a great deal of care will be taken to make the different exhibits pleasing and attractive to the eye, it should be remembered that they will be far more than mere lifeless displays. Here at the various booths will be found skilled technicians, competent demonstrators and well-informed attendants, able to answer questions or give special information on their respective subjects. Many of these men are experts or authorities in their special fields and the doctor who does not take full advantage of their prescence will miss one of the stimulating features of the annual meeting.

The floor plans shown, the index of exhibitors and the brief descriptions of exhibits on the following pages are given as an aid toward visualizing what the Victory Meeting Exposition will have to offer in the way of interest, instruction and stimulus to better practice.

Do not visit the exhibit hurriedly, or try in one hasty trip round the hall to assimilate all of the valuable and practical information that is to be obtained. Take sufficient time to go from booth to booth, making a close and studied inspection of the innovations and improvements in the accessories to medical practice which the exhibitors are placing before you at considerable trouble and expense. The exhibition will formally open at noon Monday, June 9—it will be open from 8 a. m. to 6 p. m. each day—and will close Friday noon, June 13.

While these advance notices offer a representative "preview" of the exhibition, still, many firms failed to supply advance information on their proposed displays; consequently it is left to the visitor to make a thorough tour of the Arcade, the Ball Room, and the Ball Room Balcony, to see everything that is there assembled for his benefit and information. See the exhibits and talk to the exhibitors freely, without feeling that you are expected to buy.

Dr. I. E. Leonard, *Local Chairman*

Chicago

ANESTHESIA APPARATUS

The various exhibits and demonstrations of Anesthesia Apparatus will furnish an unusual opportunity to inspect the newest and best methods in this field. Machines for hospital, office and bedside use will be shown.

—The Foregger Co., Space 121, will show a new hospital apparatus for gas-oxygen-ether vapor anesthesia on the "Gwathmey Sight Feed" style. The story of the creation of this new model may be of interest. Shortly after this country entered into the war the Foregger Co. built upon design of Dr. Chas. H. Gallagher of Ithaca, a special Army Model on the Gwathmey principle but with some new features and particularly constructed for rough handling in the war zone. Dr. Gallagher ended his career in France.

—The Scientific Apparatus Co., New York, at Space 103, will interest you in up-to-the-minute anesthesia apparatus. They will have very interesting machines to show you. Here, also, may be seen demonstrated the Anaesthetometer—an automatic ether administrator, together with the Connell Suction Insufflation Apparatus for nose and throat work.

—C. M. Sorensen Co., Inc., New York, Space 118, will demonstrate the Sorensen Tankless Air Compressor, showing both the portable and office type apparatus, used in nose and throat work for spraying, nebulizing and suction. They will also give demonstrations of the Yankhauer Tonsillotomy Outfit; also making a special show of the Dr. Bronower's Vacuum-Ether Apparatus for suction and insufflation anesthesia. There will also be an exhibit of the Dr. L. H. Coffin Apparatus, as well as the Sorensen Sinus Vacuum Cleanser.

—Toledo Technical Appliance Co., Toledo, Space 43, will exhibit the McKesson Anesthetic Appliances, confining their exhibit to three models for hospital, office and home or portable use, embodying in each the well known intermittent flow features, which regulate the administration of the gases automatically, through the action of the respiration. Each model is designed directly to meet the requirements sought, whether in hospital work, office work, or for minor operations and obstetrics in the home.

BOOKS

The past year has been very prolific in medical literature, especially works on surgery and reconstruction occasioned by the extensive work performed in the European war zone and military hospitals. Much of it has been of a high order. With practically every one of the better publishers represented in the exhibits, the physician can in a remarkably short time get in touch with the newest works and judge for himself as to their usefulness in his own work.

—P. Blakiston's Son & Co., Philadelphia, Space 116, announce that Davis' Plastic Surgery will be ready for the meeting in June. Dr. John Staige Davis of Johns Hopkins (Captain, M. C., U. S. Army) has had especial opportunity to study and investigate in this field and has written a book of unusual interest and value. Among other important works to be exhibited, are Gould and Pyle, "Medicine and Surgery," new edition, thoroughly revised, enlarged, and made even more useful than before as a practical book of ready reference; a new edition of Sequeira Diseases of the Skin; and many other of their recent practical works.

—F. A. Davis Co., Philadelphia, Space 19, will show a number of interesting new books, including Dr. Arnold Sturmdorf's "Gynoplastic Technology," illustrated with many handsomely colored plates. The recently completed DaCosta "Handbook of Medical Treatment," in two volumes, will also be in evidence. Also the new (4th) edition of Bassler's "Diseases of the Stomach," Scripture and Jackson "On Correction of Speech Disorders," and Hess' new book, "Principles and Practice of Infant Feeding."

—J. B. Lippincott Co., Philadelphia, Spaces 66 and 67, will exhibit their large line of medical, pharmaceutical, nursing textbooks and works of reference. The series of enlarged anatomical studies from Piersol's "Human Anatomy" will be a special feature. Among other new publications there will be Hirst's "Atlas of Operative Gynecology" with 210 large illustrations nearly all in color, showing the separate steps of each operative procedure; Fuch's "Textbook of Ophthalmology," fifth edition.

—The Macmillan Co., New York, Space 92, will exhibit among their authoritative medical works the new *Journal of Industrial Hygiene*, an international monthly magazine, of particular importance in this time of industrial unrest, which ought to interest government as well as medical and industrial authorities.

—The C. V. Mosby Co., St. Louis, Space 117, will show their line of standard and new medical, surgical, dental and nursing publications. Among the new works shown will be: Wall's Sex Worship, Leavitt's Operations of Obstetrics, Hertzler's Peritoneum (2 vols.), Pottenger's Symptoms of Visceral Disease, MacLeod's Physiology and Biochemistry, Levinson's Cerebrospinal Fluid, etc.

—Thomas Nelson & Bros., New York, Space 124, will interest you in the Nelson Loose-Leaf Medicine in Six Volumes. Call at this booth and learn more about this practical system of accumulating and preserving good medical literature.

—The Oxford University Press, New York, will exhibit at Space 120. The Oxford Press is 451 years old and is able to produce a list of its publications for 334 years. Since the A. M. A. Exposition is educational, this Press has decided to make some historical exhibits in connection with early printing at Oxford and some specially interesting material in regard to early medical publishing. This exhibit will include all of the Oxford Medical Publications, among which are to be noted the already famous Oxford Loose-Leaf Medicine and Surgery, the Oxford Medical Belles-Lettres, over thirty new Medical Monographs and a complete exhibit of over 225 titles.

—Rebman Co., New York, Space 53, will show a new reprint of Toldt's "Atlas of Human Anatomy." An increased use of the visual or graphic method, both in the acquirement and in the revivification of knowledge, is a feature of the age in all educational departments, and it will be demonstrated that Toldt's "Atlas of Human Anatomy" is an adequate application of the method to the study of human anatomy

—W. B. Saunders Co., Philadelphia, Space 97, will exhibit aside from the new editions of many of their standard publications, a new work on surgery, Warbasse's Surgical Treatment, the current issue of the Medical Clinics of North America, and of the Surgical Clinics of Chicago, Ewing's Neoplastic Diseases, the New Mayo Clinic Volume, Koll's Diseases of the Male Urethra, Smith's Genito-Urinary Surgery, Hirst's (J. C.) Obstetrics and his Gynecology, Griffith's Pediatrics, Rivas' Human Parasitology, McJunkin's Clinical Microscopy and Chemistry, Heineman on Milk, Sayre and Havenhill's Pharmacy, Friedenwald and Ruhräh's Diet, Overton and Denno's, The Health Officer, and several books of special value in reconstruction and rehabilitation.

—Wm. Wood & Co., New York, Space 123, invite visiting physicians to inspect their unusually attractive selection of Medical and Surgical books. This firm endeavors consistently to publish only works of real scientific value. All branches are here represented and each title is well worth looking into. Visitors will be cordially welcomed.

—The Year Book Publishers, Chicago, Space 70, will exhibit the Practical Medicine Series in eight volumes, devoted to contemporary medical and surgical progress. In its eighteen years of publication this series has become popular with the profession, meeting alike the requirements of the general practitioner and those of the specialist. The exhibit will include 1919 and previous issues.

FOODS AND BEVERAGES

More and more are we coming to depend on the science of dietetics in medical practice. Among the exhibitors will be a number of firms that are supplying scientifically prepared food products that fill special needs in the practice of medicine. Information regarding such products is an asset to any physician.

—Borcherdt Malt Extract Co., Chicago, Space 106, will exhibit Borcherdt's Malt Soup-Extract and Borcherdt's Sugar, two distinctively Borcherdt products. They will show their original Malt Soup, also Malt Sugar in crystalline form.

—The Dennos Products Co., Chicago, Space 72, will again hand out their attractive and well known prescription pencil. Dennos Food itself will be the principal feature of this exhibit, and their Pennsylvania and Ohio representative will be in charge.

—The Dry Milk Co., New York, Space 32, will show their Honor Brand Dry Milk for the first time at a Convention. They will distribute literature and supply information as to the use of Dry Milk for infants and invalids. Dry Milk has become quite a factor, and conventionists will have an opportunity to learn about its manufacture and use. Demonstration as to the condition of the curd when precipitated as compared with the curd of liquid milk will also be given. They will also show their Sterling Milk Sugar.

—The Horlick's Malted Milk Co., Racine, Wis., Space 96, will have representatives in attendance at their booth to distribute samples and furnish information regarding Horlick's Malted Milk. The value of Horlick's Malted Milk as a light, digestible, and nutritious food will be demonstrated to visitors.

—Mead, Johnson & Co., Evansville, Ind., Space 122. One of the special features of the Dextri-Maltose exhibit will be the performance of tests showing the effect of potassium and sodium salts on curd formation in milk and how this action is responsible for the production of three forms of Mead's Dextri-Maltose—one containing sodium, another containing potassium and the third being salt-free.

—The Kaffee Hag Corporation, New York, Spaces 107 and 108, will have an interesting exhibit of KAFFEE HAG. Coffee in all of its stages, from the blossom to the caffein-free article will be shown. Representatives will be on hand to welcome the visiting physicians and to tell any physician about KAFFEE HAG who is not already familiar with this well known brand of caffein-free coffee.

—Kumyss, Inc., New York, Spaces 149 and 150, will demonstrate Dr. Brush's Kumyss, "Sparkling Milk"—known for forty years as a fermented milk—digested and assimilated readily, even by the most delicate stomach. A food indicated in diabetes and nephritis; in gastric and intestinal disturbances, etc.

—Mellin's Food Co., Boston, Spaces 119 and 126, will interest you in infant feeding, a subject of serious import to physicians. In recognition of the fact that one of the important features of the Commercial Exhibit of the American Medical Association is to give physicians an opportunity to obtain information relative to products of particular usefulness to them, representatives of this company will be pleased to answer all inquiries regarding Mellin's Food and its application as a modifier of milk and to offer some suggestions that may be helpful toward a better management of an infant's diet.

—The Welch Grape Juice Co., Space 78. In this, their Fiftieth Year of National Service, Welch's Grape Juice is more generally presented than ever before. Don't forget to try Grapelade, the pure grape spread so well liked by the A. E. F. and now offered on the domestic market. It's really delicious. It will be served at their booth.

INSTRUMENTS, APPARATUS AND FURNITURE

Many new types of equipment will be on exhibition this year. A visit to these exhibits will give many valuable ideas as to new methods, new technic, etc. Here the physician cannot only see these new devices but also have their uses and advantages clearly demonstrated by skilled technical men.

—W. D. Allison Co., at Space 76, will exhibit office furniture consisting of modern appliances for physicians' private offices. They will also show their specialist's chairs, cabinets, stools, waste receptacles, extension light brackets, extension curtain brackets; the Craftsman Chair used by the specialist and the general practitioner; their examining tables, instrument and medicine cabinets, chairs, stools and various articles of interest to the profession. They will feature an irrigating table with complete outfit for irrigation that will interest gynecologists and genito-urinary men.

—An interesting exhibit presenting new ideas will be that of the A. S. Aloe Co., St. Louis, Space 71. There you will see, made in a minute, a Carbon-Dioxid Ice Pencil, 110 degrees below zero, Fahrenheit. The adaptations of the electric current to therapeutic uses will be demonstrated with the Aloe Electro-Therapeutic Cabinet. The Microscope Outfit that enables one to begin practical work the day you get it, will also be shown.

—The American Surgical Specialty Co., Chicago, Space 83, will show a line of instruments of interest to the oral surgeon and general practitioner. They have combined their electrically lighted equipment into a complete diagnostic and operating set. An especially interesting feature of their exhibit will be their Diagnostolite, a clean, cool lamp of great brilliancy, suitable for transillumination and examination.

—Bard-Parker Co., New York, Space 125, will feature the Bard-Parker Detachable Blade Knife. This knife has detachable wafer blades, operating and abscess blades, all interchangeable, made of razor steel and with razor edge.

—W. A. Baum Co., Inc., New York, Space 40, will have an exhibit of the Baumanometer, a highly developed blood pressure apparatus for use in laboratories and daily practice. The instrument is described as a "Super-Sphyg" and is a Precision Gravity-Gage for Blood Pressure. The question of blood pressure is, today, such an absorbing one that it will be of benefit to the visiting physician to inquire into the merits of this modern instrument.

—Becton, Dickinson & Co., Rutherford, N. J., Spaces 99 and 100, will display the genuine Luer Syringes, Yale Quality Needles, Bedeco Thermometers, Kehler Stethoscopes, Ace All Cotton Elastic Bandages and Asepto Breast Pumps. The new features of their exhibit will be the Ace Bandage and the Asepto Breast Pump.

—Bernstein Mfg. Co., Philadelphia, Spaces 138 and 139, will exhibit their usual line of quality steel furniture and sterilizing apparatus, where they will be glad to greet their friends.

—Frank S. Betz Co., Hammond, Ind., Spaces 7, 8 and 9, will feature specially constructed hospital furniture, consisting of instrument cabinets and a new model operating table. They also will show for the first time a high pressure sterilizer adaptable to service in every physician's office; also a very large display of American made surgical instruments.

—Wilmot Castle Co., Rochester, N. Y., Space 1, will exhibit several new "Castle-Rochester" Sterilizers. They should be of interest to all physicians who want up-to-date equipment for their offices. Besides office sterilizers, they will show a new combination outfit for use in small hospitals.

—The DeVilbiss Mfg. Co., Toledo, Spaces 25 and 26, will have a complete exhibit of their guaranteed nose and throat Atomers, for professional and home use. A first showing of new outfits recently added to their line will be of special interest. Several factory and road representatives will be in attendance.

—Charles F. Hindle, New York, Space 144, will exhibit electrocardiograph equipments for photographically recording the activities of the heart. Two models of the string galvanometer with complete optical systems and recording instruments will also be exhibited. The smaller model will be of particular interest to the physician desiring to see equipment for office use. Frequent demonstrations will be given. Typical electrocardiograms showing many of the heart's irregularities will be extensively illustrated.

—The Jaeckh Mfg. Co., Cincinnati, Space 81, will have an interesting exhibit of the latest improved Robertson Tankless Compressed Air and Vacuum Machines and Cabinets, including improved ether anesthesia apparatus with simple warming device, apparatus for evacuating and medicating the sinuses, atomizers, nebulizers, etc. Also Gold Medal hand operated compressed air outfits. Dr. Robertson will be in charge.

—E. Leitz, Inc., New York, Spaces 104 and 109, will demonstrate a number of new apparatus, possibly with representative models if they are available at the time of the exhibit.

—Charles Lentz & Sons, Philadelphia, Space 88, will exhibit a general line of Surgical Instruments, including some of the most modern instruments they manufacture for some of the leading surgeons. The new Lentz Tonsillectome will be one of the most interesting, especially to nose and throat specialists.

—The Lungmotor Co., Boston, Space 18, will demonstrate the Lungmotor, a resuscitating device of merit. Instantly adjustable—new-born to adult. Used by the U. S. Government, American Red Cross, Bellevue Hospital, leading industries, cities, hospitals, beaches, etc.

—V. Mueller & Co., Chicago, Spaces 55, 56 and 57, will have, as in former years, an extensive exhibit of instruments for the specialist in every branch of surgery. The visitors will see at this booth, practically everything that is new in instruments and apparatus for their particular line of work. Electrically driven bone surgery apparatus, electrically driven anesthesia and suction apparatus of the most modern types will be demonstrated. A special feature will be a complete collection of illuminating and exploring instruments for use in every cavity of the human body.

—Ostby & Barton Co., Providence, R. I., Space 12, will show for the first time their line of quality "Triple Crown Surgical Instruments and Needles made in the United States." These people were manufacturing jewelers for forty years. During the war they turned the energy and push of their large six story factory into the manufacture of quality surgical instruments and needles. The fine work that the skilful, careful jewelers have turned out predicts a bright and prosperous future for instruments made in the United States.

—Harvey R. Pierce Co., Philadelphia, Space 65, among other things, will feature the Albee fracture and orthopedic table, U. S. Army standard splints and other fracture treatment apparatus; also a Landon spinal mercury manometer.

—Sanborn Co., Boston, Space 82, will demonstrate the construction and operation of the improved Sanborn Blood Pressure Outfit. They will also show for the first time, another important addition to medical equipment: the Sanborn Portable Respiration Apparatus for measuring absorption of oxygen, as required in the study of total metabolism. Without gas analysis physicians will have an opportunity to observe and directly determine the amount of oxygen being taken into the respiratory system during a definite interval.

—The J. R. Siebrandt Mfg. Co., Kansas City, Mo., Space 89, will demonstrate Siebrandt's "Eveready," a modern surgical utility appliance for treatment of fractures where traction or suspension are necessary. Siebrandt's "Eveready" is a Buck's Extension, which, with its special attachment, is modified to meet every height or angle for traction or suspension.

—C. J. Tagliabue Mfg. Co., Brooklyn, Space 105, will exhibit the "Tag-Roesch" Sphygmomanometer. Interesting demonstrations will be given. Look for the sign of the "Tag."

— Taylor Instrument Companies, Rochester, N. Y., will exhibit a new design of an office type Sphygmomanometer. This instrument is so designed that it may stand on the physician's desk or be attached to a panel on the wall, well removed from the patient. The diameter of the dial is 6 inches. The oscillations on the hand of the dial by reason of the enlarged field are magnified. This instrument is designed specifically for hospitals, offices and clinics. Taylor Instrument Companies are also distributing a small booklet with the newer findings on the value of humidity in medical practice.

—George Tiemann & Co., New York, Space 68, will have many new designs of instruments of their own special manufacture on exhibition at their booth, including the Bennett, Flagg and Hasbrouck inhalers for ether and nitrous oxygen, the Boch-Benedict colorimeter, Kaliski salvarsan apparatus, Wight's blood transfusion apparatus, Kemp proctoclysis, direct light electric ophthalmoscopes and accessory instruments and a number of surgical instruments of new design.

—The Weder Mfg. Co., Philadelphia, Space 6, will display their "De Lyte Surgeon" Diagnostic Case. They will also feature their Simplex Surgeon, an interesting Pocket Surgical Set.

OPTICAL GOODS

The war has given increased impetus to the manufacture of optical goods in the United States. The various manufacturers to be represented at the meeting are now in a better position than ever before to supply the needs of the profession. A study of their displays will be time well spent.

—Bausch & Lomb Optical Co., Rochester, N. Y., will exhibit in Spaces 44 and 45. Although they took full part in wartime activities they have resumed the most of their regular service. They will show their physician's microscopes, a new model freezing microtome, and centrifuges. Particular interest will attach to the exhibit of ophthalmological apparatus, the development of which is especially notable, and to the hemocytometers which are of Bausch & Lomb manufacture.

—The DeZeng-Standard Co. of Camden, N. J., manufacturers of Eye, Ear, Nose and Throat Diagnostic Equipment, will exhibit their products in Space 11. In addition to their standard equipment, they will have several new intruments which will be shown for the first time at this meeting, among them a new Electric Ophthalmoscope, a new Electric Retinoscope and a new Phoro-Optometer. Demonstrations will be given daily by expert attendants.

—The General Optical Co., Mount Vernon, N. Y., Space 17, will show a number of instruments especially designed for ophthalmologists. During the war, almost the entire production of the company was given over to war orders. Particularly popular at their exhibit will be the Loring Ophthalmoscope. This instrument will be displayed with the other products in the Genothalmic Sets consisting of Hare Marple Ophthalmoscope, Genothalmic Retinoscope with the Crampton junior, senior or cord lighting handles. For the first time their entire new line of Genothalmic

Sets will be shown. The Hare Automatic Perimeter with the automatic color changing device will also be on display as will the Universal Ophthalmometer. Practical demonstrations will be given.

—E. B. Meyrowitz, Incorporated, New York, Spaces 38 and 39, will exhibit specialties for eye, ear, nose and throat work. Of particular interest will be their Unistat occupying a floor space of 14 x 14 inches, which produces cautery, high frequency, galvanic and diagnostic light currents, as well as pressure, suction and pneumomassage. Also to the Braun Adenotome: A combination of curette and adenotome possessing all the advantages of either.

ORTHOPEDIC APPLIANCES, CORSETS AND CLOTHING

In these exhibits will be found tried and proved appliances for correcting bone injuries, deformities, malposition; also surgical and maternity corsets, hospital uniforms, etc.

—Ambulatory Pneumatic Splint Mfg. Co., Space 79, will demonstrate the use of Ambulatory Pneumatic Splints, in the reduction and treatment of fractures of the hip, thigh and leg by means of which patient may remain out of bed. They will also show the Ambumatic Washable Abdominal Supporter. The Henning Artificial Hand and Arm will also be demonstrated.

—Anatomik Shoes will be shown at Space 3 by the Anatomik Footwear Company of New York. They will show how this well-known men's, women's and children's shoe prevents and corrects many foot troubles. Opportunity will be afforded every member of the A. M. A. who acquires "Boardwalk feet" while in Atlantic City to learn from personal experience the relief obtainable in Anatomik shoes.

—The Berger Bros. Co., New Haven, Conn., Space 35, are planning to exhibit a complete line of Spencer supports for visceral ptoses, sacro-iliac strain, intestinal stasis, floating kidney, hernia; prenatal supports, etc. The exhibit will consist of supports for both men and women.

—The Carnes Artificial Limb Co., Kansas City, Mo., will have representing them at Booth 36 one armless man and a man having lost just one arm. Both of these men will demonstrate willingly what may be accomplished by the use of a Carnes Arm, and show conclusively that a man who has lost one or both of his arms is not to be considered as helpless.

—The Earnshaw Knitting Co., Chicago, Space 75, will show how to dress a baby completely without pin or button in Vanta Baby Garments. For years theirs has been one of the popular booths, by reason of the unique and attractive display furnished, as well as by the interesting demonstrations of competent nurses representing them. This year for the first time, they will show an outfit for babies which is put on with one movement.

—Stover & Bean Co., Lowell, Mass., Space 27, will show their Socket-Fit Arch and Heel Shoe. This shoe is said to be nature-shaped, placing the foot in its natural barefoot position, and by specially constructed patterns and individual modeling of the last, holds the foot in place, giving the proper amount of support to the bones and muscles so that there is no undue pressure or strain on any part of the foot.

—Weissfeld Bros., New York, Space 80, will show their Hospital Wearing Apparel, a most up-to-date line. Uniforms for the surgeon, the nurse and office attendant. A fine line of Palm Beach and Mohair suits will also be on exhibition. A souvenir given to every visitor.

—The Wright Wire Co., Worcester, Mass., Space 31, will exhibit their Excelsior Universal Wire Gauze Splint; also their Excelsior Automobile Towline. The splint is furnished rolled, the size of an ordinary roller bandage, and enclosed in a paper carton. The towline is made of steel wire cable, five-sixteenths inch in diameter, with manila slings and sister hooks for ready adjustment, and all enclosed in a canvas bag.

PHARMACEUTICALS AND BIOLOGIC PRODUCTS

The work of the physician is so intimately dependent on these products that an acquaintance with the different pharmaceutical houses, their preparations, their service, etc., is often of great advantage. At the Commercial Exhibit is his opportunity to meet representatives of such firms, and see pleasing displays of their new as well as standard remedies and secure information about the application of these remedies, which will be of practical value in every day work.

—The Abbott Laboratories, Chicago, Space 69, will feature American-made medicinal chemicals. Not only will they exhibit a full line of the Dakin antiseptics, Chlorazene, Dichloramine-T, Chlorcosane and Halazone, but they will bring in evidence several American-made synthetic medicinal chemicals for which it holds licenses from the Federal Trade Commission under German patents. Special attention in this exhibit will be given to Barbital, Procaine and Phenylcinchoninic Acid.

—Armour & Co., Chicago, Space 113, will exhibit a complete line of endocrine gland preparations and organotherapeutic agents; and will also show their Sterilized Surgical Catgut Ligatures, plain and chromic. The Armour Ligatures are manufactured from material selected especially for surgical purposes. Pepsin, Pancreatin, Thyroids, Corpus Luteum, Pituitary Liquid and other endocrine gland preparations will also be featured.

—B. B. Culture Laboratory, Inc., Yonkers, N. Y., Space 2, will exhibit B. B. Culture, a liquid suspension of Bacillus Bulgaricus. The advantages of the preparation as a biologic antiseptic in internal and external use will be explained and microscopic slides of the culture shown. Complimentary bottles will be mailed to visiting physicians who leave their names.

—The Hollister-Wilson Laboratories, Chicago, will exhibit at Spaces 94 and 95 their long-established line of Ligatures, Sutures and Surgical Material, and will show in addition a full line of glandular Autacoids, Organic Extracts, Enzymes and Abattoir Pharmaceuticals. By proper laboratory methods they are able to assure the identity and therapeutic activity of the Autocoids, Enzymes or Organic Derivatives represented in the finished product.

—Hynson, Westcott & Dunning, Baltimore, Space 114, will introduce new ideas in the manner of showing their products. A competent staff of representatives, under the direction of Mr. W. Rodney Burton, will be in attendance to give visiting physicians just such information as they desire regarding the firm's therapeutic specialties and diagnostic agents and appliances. The new local anesthetic — Phenmethylol — and the new antispasmodic—Benzyl Benzoate—will be interesting features.

—The Kolynos Company, New Haven, Conn., Space 20, will exhibit experiments demonstrating the germicidal properties of Kolynos Dental Cream and illustrating its destructive power against both pathogenic organisms and those nonpathogenic bacteria which are believed to play an important rôle in the development of dental caries. The Kolynos Co. maintains chemical and bacteriological laboratories devoted to research work in oral hygiene.

—The Maltbie Chemical Company, Newark, N. J., Space 112, the manufacturers of Calcreose, will display the various forms in which Calcreose, a combination of calcium with pure beechwood creosote, can be administered, solution, powder and tablets, in original packages, and will have for distribution all information available as to the effectiveness of this new creosote product.

—The Maltine Company, Brooklyn, Space 101, will exhibit its well-known line, making a particular feature of Maltine Malt Soup Extract, with which the preparation of Malt Soup, as devised by Keller, becomes easy and satisfactory. Visiting lists and sets of memorandum books will as usual be presented to visiting physicians.

—H. A. Metz Laboratories, Space 135, will present to conventionists an exhibit of their products, Salvarsan (Arsphenamine-Metz), Neosalvarsan (Neoarsphenamine-Metz), and Novocain (Procaine-Metz). Methods of preparation of salvarsan solution will be demonstrated and other unique features will be presented; which promises to make this display particularly interesting to every visiting physician.

—The Pulvola Chemical Company of Jersey City, Space 4, will exhibit their line of nonabsorbent powders—the Dolomol Stearates, Pulvola Toilet ("The Doctors' Baby Powder") and Pulvola Foot Powders. They will show their odorless, tasteless, impalpable, dry, white Ichthyol—as combined with Dolomol. Their unique demonstration, "The Tale the Two Tumblers Tell," is an eye-opener on toilet powders and "dry ointments," and invariably attracts attention and keen interest wherever shown.

—The Radium Chemical Company of Pittsburgh, Space 111, will display a full line of surface and cavity applicators, including necessary screens, etc. Their representatives will give demonstrations of the physical properties of radium, and will be prepared to discuss the technic of its application. Conventionists are cordially invited to visit their Laboratories at Pittsburgh, either before or after the meeting in Atlantic City.

—E. R. Squibb & Sons, New York, Spaces 15, 16, 21, 22 (band stand), in addition to their chemical and pharmaceutical preparations, an instructive display will be made of their biological and biochemical products. The position of the band stand, which has been secured for their exhibit, makes it possible to plan such a comprehensive display that it cannot fail to attract and hold the interest of the visiting physician.

—The Takamine Laboratory, Inc., New York, Space 84, intend to hold clinics for the benefit of conventionists, showing the method of making solutions and the proper injection of Arsaminol and Neoarsaminol. The clinic will be in charge of a biologist of note, and physicians are cordially invited to attend it.

X-RAY AND ELECTROTHERAPEUTIC APPARATUS AND ACCESSORIES

The applications of roentgenology and electrotherapeutics have increased so rapidly that it is difficult to keep apace. This year's exhibits of x-ray outfits and other electrical equipment will show many of the recent advances in this field, and likewise reveal to the physician the extent to which the various manufacturers are cooperating with the profession by furnishing the machinery, supplies, etc., for doing this important work.

—The Baker Electric Co., Hartford, Conn., Space 141, will show their Baker Military Model T Static Machine. Powerful, light and compact. Ample capacity for all standard static work. Standardized, calibrated, graduated. You will be very welcome; their booth is at your service, and they will feel it both an honor and pleasure to show you what they have and to give any explanation and information you may desire.

—The Campbell Electric Co., Lynn, Mass., Spaces 86 and 87, will exhibit a Sure X Transformer, such as they furnished to equip the Mexican border hospitals and the original Pershing Expedition and over 100 reconstruction and debarkation hospitals in France and the United States. The Campbell Motor Driven Tube Tilt Table, besides the latest Bedside Coolidge Unit and a complete line of high frequency apparatus, will also be shown.

—The Chicago Surgical and Electrical Company, Chicago, Space 110, will show an entirely new apparatus, the Electrothermophore, for the treatment of specific urethritis by heat, superinduced from electricity. Many other new apparatus will also be shown, well worthy of attention.

—The Eastman Kodak Co., Rochester, N. Y., Spaces 46 and 47, will make an exhibit of the possibilities of x-ray photography with Eastman Dupli-Tized X-Ray Films under standard conditions of exposure and development with the various types of small machines now on the market. They will also display negatives made with Seed X-Ray Plates. Their whole exhibit will be designed to emphasize the increased effectiveness of diagnosis obtained by the use of standard photographic methods.

—The Engeln Electric Company, Cleveland, Space 54, will show their new Portable Universal Stereoscopic X-Ray Unit with Coolidge Radiator Type Tube, which is a complete Roentgen Plant in one unit, something entirely new and different. The Portable Fluoroscopic Unit and Dental Coolidge Tube X-Ray Unit will also be shown. This apparatus represents a late development in Roentgen Laboratory practice and will prove instructive.

—H. G. Fischer & Co., Chicago, Space 59, will show their latest Interrupterless Transformer X-Ray equipment, No. 2. The many improvements in x-ray generating apparatus during the war will be noticed in this apparatus, for it is their latest model. In addition, the smaller high frequency apparatus will be demonstrated, including the Suit Case Portable Coil. A full and complete line of standard x-ray accessories will also be shown.

—The Hanovia Chemical and Mfg. Co., Newark, at their Booth 98, will offer visitors an opportunity to thoroughly inspect their Quartz-Mercury Arc Lamps, as designed for the use in modern therapeutic practice. Their Alpine Sun Lamp and Kromayer Lamp will be put in actual operation, and competent demonstrators will be on hand to explain in detail their therapeutic use and value.

—The exhibit of the Kelley-Koett Mfg. Co., Covington, Spaces 90 and 91, will consist of an x-ray equipment of a condensed type, designed with especial reference to the requirements of hospitals and clinics, wherein it is desired to handle all branches of x-ray work within a minimum floor space and with the least possible noise and vibration. Their new Bedside Unit will be here shown for the first time, as well as a number of post-war accessory novelties. The government method of localizing foreign bodies will be demonstrated with their portable trochoscope, as used in France.

—The McIntosh Battery & Optical Co., Chicago, Spaces 63 and 64, will exhibit the results of their forty years of experience as manufacturers of electrotherapeutic equipment by displaying the Hogan Silent Roentgen Transformer, which is giving such splendid satisfaction in connection with the new Green & Bauer Self-Rectifying Tube; also Universal modes, Polysine Generators and Bristow Coils, which are being used extensively in reconstruction hospitals throughout the United States and Canada. A visit to their booth will be of educational value.

—Thompson Plaster Co., Leesburg, Va., Spaces 60 and 61, will have the largest display they have ever had of their X-Ray and Electrotherapeutic Apparatus. They will exhibit for first time their new oil immersed transformer F—a high type, high power treatment outfit that can be run continuously also their new Eurisco, an outfit built specially for nose and throat men—a complete equipment in one cabinet; also two styles of X-Ray Interrupterless X-Ray Transformers.

—Victor Electric Corporation, Chicago, Spaces 48, 49, 50, 51, 52. Their exhibit will contain more new apparatus and appliances than were ever shown at any one of their exhibits. In addition, several of the standard Victor equipments with new improvements will be on display.

—The Wappler Electric Company's exhibit, New York, Spaces 23 and 24, will contain their latest Bellevue Model Roentgen-Ray machine with oil-immersed transformer, one hundred step autotransformer and twenty step rheostat control. An important feature of this exhibit will be their Universal Stereoscopic and Fluoroscopic Table, which embodies a new self-balancing plate-shifting device and adjustable screen holder. The NitroKen tube (recently developed by the Wappler Co.) will also be in evidence. Of interest to electrotherapists will be the Telatherm and the Portable Telatherm, designed for U. S. Army hospitals.

UNCLASSIFIED

—The American Medical Association, Chicago, will have an exhibit of A. M. A. publications, and will present for the first time at a convention the new A. M. A. auto emblem which will interest every physician who drives a car. This exhibit in connection with the Superintendent's office, will be located in the Ball Room balcony, at the head of the left stairway.

—Dennison Mfg. Co., Framingham, Mass., Space 130, will make an attractive exhibit showing crepe paper bandages as efficient economical substitutes for the ordinary bandage. They will also have their *Surgical Dressing Pads made from a very absorbent paper and other specialties*, including tray covers with new embossed hemstitch edge effect, paper sputum pads, towels, napkins and surgical caps.

—S. W. Nourse, Palisade, N. J., Space 85, will have an interesting exhibit of Scientific Photography, illustrating how essential it is to have good photos for records, for publication and teaching; lantern slides from x-ray plate that will show the points of interest; a method of showing x-ray plates of a standard size from all the different sizes of x-ray plates without the risk of loss of the original; photos of patients before and after operations; pathological specimens photographed to metric scales; photomicrographs and other items of timely inetrest to the general practitioner, specialist and laboratory man.

—Waterproof Fabric Company, Chicago, Space 74, will exhibit Sani-Dri, a nonrubber waterproof fabric, and its merits will be demonstrated. Sani-Dri has given universal satisfaction to a large number of users for the past four years. Not only will the exhibit be interesting; it will be of practical value to the visitor. Be sure and get a complimentary surgical dressing.

DIFFERENTIAL DIAGNOSIS OF PEPTIC ULCER *

WILLIAM FITCH CHENEY, M.D.
Clinical Professor of Medicine, Leland Stanford Junior University School of Medicine
SAN FRANCISCO

The diagnosis of gastric and duodenal ulcer is not made so frequently now as it was ten or eight or even six years ago. In 1912, for instance, the total number of patients seen for diagnosis, all of them with medical ailments and a large proportion complaining of "stomach trouble," amounted to 445; and among these a diagnosis of ulcer, gastric or duodenal, was made in twenty-eight. In 1918, with a total of 461 cases, the diagnosis of ulcer was made only ten times. The main reason for this decrease lies in the more rigid tests gradually adopted, and the attempt to substitute demonstration for inference, before a conclusion is reached.

The data on which the diagnosis of ulcer depended only a few years ago were obtained from history, physical examination and analysis of gastric contents.

IMPORTANCE OF THE HISTORY OF THE CASE

The history was considered of special importance and almost diagnostic. The well known points in this history are its chronicity, extending over years; its remissions, for weeks or months, during which the symptoms are absent or much less severe; its rhythmic cycle of events while an attack persists; the manifestations all relieved by taking food, but recurring at a variable interval after eating, and then increasing rapidly until food is taken again, or some remedy, such as soda, or until vomiting occurs; finally, the character of the patient's symptoms, such as heartburn, belching, water-brash, nausea and often severe pain before vomiting gives relief—in general, a complaint of acidity and sour stomach. If to these details there was added the story that the vomitus contained blood; or if a patient was first seen with hematemesis and presented a history of long-standing "sour stomach" preceding, gastric ulcer assumed the first place in the diagnosis.

Two facts, however, have gradually impressed themselves on me; first, a history such as the one outlined does not invariably mean ulcer; and second, ulcer may exist even though the history does not correspond to the usual type. One becomes convinced, as years accumulate experience, that the so-called ulcer history is only a hyperacidity history; that any condition giving rise to hyperacidity may thus simulate ulcer; and that to infer ulcer from history alone frequently leads to error. On the other hand, ulcer may exist without hyperacidity, with normal or subnormal acid values, and thus without presenting the familiar story we have learned to expect. Furthermore, experience with cases observed during the past thirteen years, on the records of which this paper is based, teaches that vomiting of blood is not a common incident of ulcer; and in 136 cases observed during the past six years, in which the diagnosis of ulcer seemed clearly demonstrated by all the methods to be described later on, hematemesis occurred in only fifteen. It is also a well known fact, confirmed by numerous observers, that hematemesis may occur in association with hyperchlorhydria from any cause, when no ulcer exists.

THE VALUE OF THE PHYSICAL EXAMINATION

Physical examination has always been considered chiefly of value in ulcer for the negative evidence it presents. The only sign expected was a point of tenderness elicited on pressure over the epigastrium, or one or the other hypochondrium. But this evidence, of course, is entirely subjective and dependent on the patient's varying sensibility to pain; so that neither its presence nor its absence is conclusive. There has never been any objective sign of ulcer, nothing that could be definitely seen or felt by the one examining. A tumor palpable in the gastric area may very rarely, in a thin-walled abdomen, be due to the cicatricial tissue of an old ulcer; but such a tumor must always be looked on with suspicion, is always more likely to be a neoplasm, and ought always to be considered of sufficient seriousness to justify exploratory laparotomy. The discovery of a peristaltic wave across the stomach, from left to right, means pyloric obstruction and hypertrophy of the gastric walls; but it does not by itself indicate ulcer any more than it does cancer or adhesions, as a cause of the obstruction. The entire absence of any abnormality on physical examination has thus long been assumed to be characteristic of ulcer, when the history has already created an impression that ulcer exists. But we now know that several other intra-abdominal conditions, such as an obliterative appendicitis or a gastroptosis, may present a similar absence of physical signs, with an exactly similar ulcer history. Likewise tabes dorsalis may produce recurring gastric attacks closely simulating those of ulcer, with entirely negative findings over the abdomen on physical examination.

ANALYSIS OF STOMACH CONTENTS

In times past, all clinicians have depended much for diagnosis on the analysis of the stomach contents. The characteristic finding was hyperacidity; and when this was proved to exist. after a typical history had been

---

* Read before the San Francisco County Medical Society, April 8, 1919.

elicited and a tender spot in the epigastrium had been found, the last bit of evidence was supposed to have been adduced to justify a diagnosis of ulcer. It is true, on the one hand, that ulcer is most often associated with hyperchlorhydria, although it may be found with acidity within normal limits or even below normal. But hyperacidity, on the other hand, may be associated with numerous other conditions besides ulcer. And so the old diagnostic combination of characteristic history, negative physical findings, and stomach contents showing hyperacidity can no longer be depended on. A conclusion based on these data alone used to lead us constantly into error, and would do so still, if we had no other aid in reaching the truth.

VALUE OF FLUOROSCOPY AND ROENTGENOSCOPY

Fortunately we have now another method of obtaining information, namely, by fluoroscopic examination and by roentgenograms of the gastro-intestinal tract. This mode of investigation has gradually developed during the past decade until now it has become indispensable; and in no case of suspected ulcer should a conclusion be reached without its aid. The information thus obtained about the outlines of the stomach and the duodenal cap, the rate of peristalsis and the emptying time of the stomach, adds demonstration to inference and either confirms or disproves the suspicion aroused by history, physical examination and analysis of stomach contents. We have learned, if no evidence of ulcer appears from the roentgenographic examination, to distrust all the other evidence, no matter how convincing it appears. On the other hand, apparent defects in the outlines of the pylorus or the duodenal cap, suggesting the presence of ulcer, should not be interpreted as positive proof unless other evidences coexist, in history and stomach analysis. This whole question of the results obtained by gastro-intestinal roentgenographic examinations is a very serious one for the clinician; for no man can devote his time both to clinical investigation and to roentgenographic technic without doing injustice to one or the other; and as a consequence each part of the work ought to be entrusted to a specialist in his own line. It is well known that improper technic may easily cause defects to appear in roentgenograms that do not really exist in the body, and the roentgen-ray technician must know how to avoid these and how to interpret what the plates show. He must be willing to repeat examinations to confirm dubious results, and not too ready to furnish a diagnosis from his findings alone. What the clinician wants is roentgenographic evidence, not roentgenographic diagnosis. This evidence is of great value, but only when taken in connection with that obtained by other methods previously described. Taken alone, it is worse than worthless, because it is misleading and confusing.

OTHER CONDITIONS PRODUCING SYMPTOMS RESEMBLING ULCERS

The question next arises, What other conditions may produce symptoms and signs resembling those of ulcer, and how are we to avoid mistaking one for the other? It is surprising how many times we find now, with our increased facilities for study, what we suspected to be ulcer proves to be something else altogether; but, on the other hand, we know with greater certainty when ulcer does exist and we make fewer errors in its recognition than we used to make.

1. *Chronic Appendicitis.*—This deserves first place when we consider the conditions that simulate ulcer, because it often leads to hyperchlorhydria and so to the typical ulcer history. So far as we know, anything that delays the emptying of the stomach results in hyperacid secretion, and in chronic appendicitis it is a reflex pylorospasm that produces this result. From the history alone, it is often absolutely impossible to decide that ulcer is not the cause of the stomach symptoms that follow. The patient's attention is directed to the stomach, and of this alone he complains. Yet if questioned closely, he may recall intestinal upsets at times in addition to the stomach trouble, such as occasional attacks of cramps and diarrhea, attributed to some improper food or to "ptomain poisoning." He may even recall periods when for days at a time he felt sore and tender in the right lower abdomen. His history is frequently one of chronic constipation and of repeated resort to cathartics, especially when his stomach condition is worst. In all these details we get a clue to the possible existence of trouble in the appendix, even before physical examination is made. Of course, if definite tenderness and rigidity and muscle spasm, and a palpable thickening are found over the appendix, this organ will be suspected as the cause of the stomach complaints. But so often the signs are vague and indefinite in this area, especially with the so-called obliterative appendicitis, that they may be overlooked on repeated examinations and by the best observers, and the real cause of the stomach symptoms will be assumed to be in the stomach itself, particularly after gastric analysis reveals a high grade hyperchlorhydria. But if in such a case the roentgenographic report is negative as regards ulcer, that diagnosis must certainly be reconsidered; and if, on fluoroscopic examination, it is equally positive as regards tenderness at the appendix site, delay in the cecum or in the appendix itself, with evidence of fixation of the cecum to the abdominal wall, then the diagnosis of chronic appendicitis can be reached with sufficient certainty to justify surgical procedure. There seems no excuse these days for the old error, so frequently made, of an operation for ulcer, resulting in the discovery of no ulcer present, followed by a second incision over the appendix for its removal. It is always possible to decide this question in advance, before the case is sent to the surgeon, if only sufficient care is taken to get all the evidence together, and sufficient judgment is exercised as to what the evidence means.

2. *Chronic Cholecystitis.*—Not all chronic inflammation of the appendix simulates ulcer, nor does all chronic inflammation of the gallbladder, but only those groups of cases in which hyperchlorhydria is present and the chief complaint is of the stomach. In gallbladder disease, as in appendix disease, this group is a large one; and the patient's story is so persistently made up of the symptoms characteristic of ulcer that it frequently misleads. In addition to these symptoms, however, there is another set in the background, comprising occasional attacks of soreness and pain in the right side at the costal margin, a sense of fulness and distention there as if something was in the way, a feeling of lameness and stiffness on movements of the body involving that side. If these attacks develop into sharp paroxysms of colic, with transient jaundice, they seldom fail to be remembered; but lesser manifestations may be withheld from the patient's history, so intent is he on relating his stomach disturbances and

so unimportant do the other incidents seem to him in comparison. Physical examination soon after one of these exacerbations of a chronic gallbladder inflammation may reveal much tenderness and definite muscle spasm at the right costal margin, with increased fulness and tension there; but at other times no evidence whatever may be found to make one suspect the gallbladder, and physical examination may be set down as negative. The stomach analysis shows hyperchlorhydria, but nothing to indicate either ulcer or gallbladder disease as a cause. The roentgenographic examination, however, gives valuable assistance in differentation; on the one hand, eliminating the evidences of gastric or duodenal ulcer; and on the other, by demonstrating a high hepatic flexure, and perhaps a stomach drawn to the right, indicating adhesions of the gallbladder to the surrounding organs from pericholecystic inflammation. At times the outlines of an enlarged gallbladder can be made out in the roentgenogram; and in a certain proportion of cases gallstones are apparently demonstrated; but these findings are not certain enough to be relied on, so that neither their absence nor their presence is conclusive. But the data as thus collected will make the ultimate diagnosis practically certain; so that no patient should by error be grouped these days among the ulcer cases when his real disease is in his gallbladder.

3. *Gastroptosis.*—We owe to roentgenographic evidence our discovery of the frequency with which prolapse of the stomach occurs. It is true that this faulty position does not always cause symptoms and may exist without giving rise to any complaint whatever on the patient's part. It is also true that its manifestations, when they do occur, are of several different types. But there is undoubtedly one large group of gastroptosis cases that closely resembles ulcer. This is because of the hyperchlorhydria that results from the faulty position. The explanation for this hyperacidity lies, as always, in the delay in emptying of the stomach, probably because of the drag on the attachment of the duodenum, which cannot descend freely with the stomach, even though the greater curvature lies below the pelvic brim. The highest degrees of hyperchlorhydria are frequently found with this condition, and the consequence is a history corresponding closely with that of gastric ulcer, in no way to be distinguished from it. Physical examination is absolutely negative as regards the stomach and abdomen, except for the discovery of a prolapsed right kidney which frequently occurs coincidently with the gastroptosis, and except after the old method of inflation of the stomach with carbon dioxid, which shows the stomach outlines abnormally low but never with the same accuracy as demonstrated by the fluoroscope or the roentgenogram. This absence of any signs on physical examination, except for epigastric tenderness, which is as common in one case of hyperchlorhydria as in another, is of course one of the characteristics of ulcer. As regards the roentgenographic evidence, it excludes ulcer, on the one hand, no matter how firm our preconceived notion of the case, formed from history, physical examination and analysis of gastric contents; and it demonstrates gastroptosis, on the other hand, more definitely than any other method can. While there are differences of opinion as to how low in the abdomen the stomach may normally be found, there seems to be agreement that a greater curvature lying below the level of the iliac crests constitutes an undoubted abnormality. Symptoms may arise, however, even with lesser degrees of prolapse, and this fact must be remembered. The therapeutic test confirms the diagnosis, for a properly fitted abdominal support, holding up the stomach, brings relief gradually of all symptoms. It is significant that in former days of less accurate diagnosis, the classical treatment for ulcer has always been prolonged rest in bed and a diet of milk and cream that increased weight. This treatment today is just as effectual for gastroptosis, for the rest in bed and increase in abdominal fat restore the stomach somewhere near its normal position, even without external support. Possibly some of the cases formerly called ulcer and cured by routine treatment were really gastroptosis.

4. *Gastric Cancer.*—Usually the history in cancer is entirely different from that in ulcer, as regards shorter duration of symptoms, their persistence without intermission, and their character. But not infrequenly cancer occurs on an ulcer base, and the history then becomes confusing and no longer characteristic. Symptoms may have persisted for years, with intervals of comparative good health between attacks, and the details of these former symptoms may correspond in every respect to those of ulcer. But when cancer develops, the story is of a change in the manifestations; the pain becomes more constant; food is not desired; soda and other remedies, as well as food itself, no longer give relief; taking food causes distress at once, with no interval of comfort following; and the patient loses in weight and color as in no previous ulcer attack. Physical examination now may show definitely a tumor in the upper abdomen. Its presence, as already stated, is always to be looked on with suspicion; though its absence does not exclude cancer, because it may be concealed and out of reach.

The characteristic stomach contents in cancer are usually altogether different from those in ulcer; with poor trituration of the test meal, and complete absence or great decrease of free hydrochloric acid. But when cancer has developed as a sequel of ulcer, the secretion of hydrochloric acid may continue to such an extent that the amount is normal or only moderately subnormal for some time after malignant degeneration has taken place. Finally, whether or not a palpable tumor has been found, the roentgenograms will show its presence or absence and its site, if present. The appearance of the filling defect in cancer is usually different from that in ulcer, so that a conclusion can be reached as to its meaning; but in making a diagnonsis, the data elicited by history, physical examination and gastric analysis must all be taken into account, as well as the roentgenographic findings; and in case doubt still exists, it is wiser to advise exploratory operation without too much delay.

5. *Other Intra-Abdominal Pathologic Considerations.*—There are other conditions that now and then give a history closely resembling that of ulcer because they produce hyperchlorhydria; but they can usually be recognized and differentiated if only care enough is observed in collecting the data. Such, for instance, are intestinal parasites, especially tapeworm, which can never be missed, however, if the stools are examined for segments and ova. Small hernias due to defects in the abdominal wall, around the umbilicus or along the linea alba above it, may reflexly cause hyperchlorhydria and its usual train of symptoms; but such protrusions, even though very slight, can be found if

search is made for them. The absence of other physical signs and the negative findings in roentgenograms prove that other cause does not exist for the history; and correction of these defects, with prevention of further intestinal or omental pinching, removes the gastric symptoms. Chronic pelvic inflammatory disease in women, and old adhesions involving the intestinal wall in a former peritonitis, are other conditions that at times may simulate ulcer in the way described. Pelvic examination, giving direct or positive evidence, and roentgenograms giving indirect or negative evidence, call attention to the site of the real pathologic condition.

6. *Gastric Crises.*—The hardest lesson to learn about abdominal disease is that of "gastric crises," due to no disease within the abdomen itself, but to disease in the spinal cord. These crises come at irregular intervals, weeks or months apart, with good health between. They last for days or weeks, and the attacks are characterized by intense pain and by vomiting, so that the patient fears to take food and cannot keep it if he does. No wonder the first thought with such a history is of some disease of the stomach; and commonly of ulcer as corresponding most closely in its manifestations. The physical examination of the abdomen is negative in such case; and the stomach contents most often show hyperchlorhydria after an attack is over. It is not surprising, therefore, if such symptoms have in the past misled us, even to the point of advising a gastro-enterostomy to prevent their repetition. Now, however, the negative roentgenographic findings come to our rescue, to save us from error; and at all times, even without roentgenograms, we have other definite signs to point out the real disease, if only we take the trouble to look for them. First, these signs consist in alteration of reflexes, in one pupil or both; in patellar or Achilles tendons, perhaps only on one side; or in the plantar reactions to stimuli. Second, and most important, lumbar puncture and examination of spinal fluid for cell count and Wassermann reaction afford the most constant clue to the real disease present.

Gastric Neuroses.—These are still mentioned in the textbooks, in the differential diagnosis of ulcer, but their existence outside of textbooks must be considered very dubious. A history resembling that of ulcer, with hyperchlorhydria, does not occur without some pathologic condition somewhere in the body, usually in the abdomen, to explain it. In times past this "acid dyspepsia" has been considered as a possible result of a disturbance of the nervous system only; but such a supposition, with our increased facilities for eliciting facts, is no longer tenable. The exact cause of the clinical picture may not always be obvious, but one always exists, and careful search will sooner or later reveal it.

CONCLUSIONS

We have heretofore been too ready to diagnose ulcer, when it did not exist, because the history was typical; but now we have learned how many other conditions may simulate this history, and we demand other data in addition to the patient's story. On the other hand, when the history was not typical, ulcer was not suggested by it and we were likely to overlook its existence because our other means of recognition were so meager. Now we have learned that the patient's story of his ailment is not always the same; that some feel less discomfort from an ulcer than others do; and that only a part of the classical symptoms may be present, even when hyperchlorhydria is found and roentgenograms show definitely a pyloric defect or a deformed cap. The only way to avoid error, therefore, is to trust to no one element in the diagnosis; but to collect our data by history, by physical examination, by laboratory reports, and by fluoroscopic examinations and roentgenograms; and then to piece these data together as a child does the parts of a picture-puzzle, to see what they will ultimately make. Fifty years ago Thomas Huxley wrote:

> Sit down humbly before facts as a little child, be prepared to give up every preconceived notion, follow humbly wherever and to whatever abyss nature leads, or you shall learn nothing. I have only begun to learn content and peace of mind since I have resolved at all costs to do this.

THEORIES REGARDING BLOOD PRESSURE

HAROLD W. DANA, M.D.
Formerly Major, M. C., U. S. Army; Formerly Chief Cardiovascular and Lung Examiner, Medical Officers' Training Camp, Camp Greenleaf, Ga.
BOSTON

For a number of years, there have appeared from time to time books by various authors purporting to give to the reader a complete understanding of blood pressure, the causation and the measuring of changes in the various factors, and the blood-pressure conditions to be found in all diseases. Independent observers have also put forth formulas for the determination, by means of blood-pressure estimation, of cardiac efficiency.

Recently I have had the opportunity of studying blood-pressure findings in a large number of army officers and candidates for commissions in the army, chiefly in men over 30 years of age, medical officers being in a large majority. I am not here presenting statistics as to the distribution of these cases among different age periods, or as to the classifying of the blood-pressure readings obtained; for, while these figures might be of interest, it does not seem to me that such statistics help us to understand the conditions presented by the individual. What I wish to do is to point out some of the conditions met in this mass of material, to discuss the interpretation of the findings, and to suggest a new point of study in the analysis of blood pressures.

Most of the medical officers examined came to camp from a considerable distance, and were examined the day after their arrival, without opportunity for rest after the long journey. Being physicians, they were almost universally very nervous over the ordeal of the examination. Most of them were naturally constipated, and this constipation was increased by the journey, by the change of routine, and by the change in diet. To many, sleep under camp conditions was at first difficult. From all of these causes, it was not surprising that a large number of the candidates showed an elevation of the systolic blood pressure. In a great majority of such cases, however, rest, catharsis, and the fact of becoming accustomed to the new routine of life, soon brought the blood pressure down to within normal limits. It served to demonstrate in a very striking way the effect of overwork, nervous strain, psychic stimulation, and constipation, in raising blood pressure.

One fact that impressed me particularly is the frequency with which one meets a familial hypertension. Such a condition of continued elevated systolic pressure, in which most members of particular families share, the tendency apparently being hereditary, does not seem in such families to cause invalidism or to shorten life. Indeed, it has seemed to me that many such individuals with a sustained hypertension continue to have better than normal health and robustness; and that the hypertension, if it were not actually the cause of this, at least went hand in hand with their abundance of strength.

With a superabundance of energy and an abnormal vitality, one physician, 48 years old, 6 feet tall, weighing 190 pounds, hard as nails and the picture of health, had a constant systolic pressure of 190 to 200, with a diastolic of 110 to 120. He told me that his father was over 80 years of age, vigorous and active, in spite of a systolic pressure that had been around 200 mm. for years. The officer in question and his brother, three years his senior, had each of them presented similar pressures for years, yet had had the best of health. This officer showed a negative urine, a normal heart, no thickening of the peripheral arteries, and normal eye grounds.

Such a condition shakes our faith in any preconceived standard for normal systolic pressures. These familial hypertension cases as a general thing, in my opinion, can be accepted as representing to all intents, and for that particular family, a condition free from serious organic disease. Another type in which there is difficulty in setting down a standard for normal blood pressure is the case in which the hypertension is compensatory to renal or arterial disease. In this general category come those cases in men of 50 years or over in which the blood pressure has assumed a probably normal and physiologic elevation. Taken by and large, our conception as to what represents an unduly high systolic blood pressure in a given individual must take a good many facts into consideration, must be highly individualized, and must have considerable latitude, both as to the standard accepted and the interpretation to be placed on deviation from the standard.

Certainly I am not at all willing to concede that a high blood pressure, for example, 200 mm., means necessarily any of the things that we have always agreed that it did mean. It does not seem to me a proved fact that marked hypertension necessarily causes apoplexy; that it necessarily increases the probability of apoplexy, or of renal or arterial disease, or of ill health of any kind. If marked hypertension means of a certainty any of these things, why do some men live to far beyond the average age, in spite of continued marked hypertension of long duration? Granted that some pathologic condition would have been found present after death in these cases; granted that signs of nephritis or of arterial degeneration might have been present, proof is still lacking that the hypertension was the result of the lesions found; for, after all, if there were not some cause for the termination of life, these fortunate beings would have lived forever; and in my opinion any man who enjoys reasonably good health and an active life—as many men with marked, continued hypertension do—until past 75 or 80 years comes to his final end for the reason that his body is not immortal and is constructed to last for only seventy years or thereabouts.

Why is it that a considerable proportion of men with sclerosis of the peripheral vessels have a normal blood pressure, and that in a similar proportion of cases of hypertension there are soft radial arteries? Is it not true that we are putting undue weight on the occasional coincidence of hypertension and arteriosclerosis?

We have had certain standards set down for us by the pioneers in sphygmomanometry, most of which we have accepted blindly. Unfortunately, there has been little opportunity for exact observation correlating physiology and pathology along this line, and it seems to me that most of the supposed facts of blood pressure that we accept are still open to proof and subject to doubt.

Probably we can accept without serious question that the systolic pressure represents the point at which sounds are first heard with the stethoscope over the cubital fossa when the pressure in the cuff is dropping, and that the diastolic pressure is the lowest point at which these sounds pass their maximum, that is, the beginning of the "fourth phase."

What does the systolic pressure represent? We have been taught that a constant high systolic pressure indicates a permanent change in the capillaries, particularly the renal capillaries. Yet, if such be the case, why is it a fact that some patients with high systolic pressure may have their blood pressure lowered and kept at a normal level by repeated treatments, either with high frequency currents or with radium emanations internally? Incidentally, I would point to this influence of the high frequency currents or radium emanations on blood pressure, through their action on metabolism, presumably in oxidizing or otherwise destroying toxic products in the body, as supporting my theories as to the causes of individual blood-pressure readings. If there is actual change in the renal circulation, of such a nature that the capillaries can no longer dilate, then it must be a fact that an increase in systolic pressure is necessary to drive the blood through the kidneys. But it is a fact that many patients with contracted kidneys and high systolic pressure may be freed from symptoms for years and have a blood pressure normal for their age, as the result of treatment. This, to my mind, is explained by the theory that the systolic pressure, while a measure of peripheral resistance, and as such, a compensatory mechanism in these cases, is not the result of permanent changes in the renal capillaries, but is the effect of vasoconstriction, due to toxins circulating in the blood. Many cases of acute focal infection give rise to a temporarily increased systolic pressure, to be accounted for in the same way.

Similarly, many cases of hyperthyroidism present an elevated blood pressure. The effect of nicotin in raising systolic pressure is well known. It has been demonstrated to my satisfaction that the presence of constipation causes a rise in blood pressure. To my mind, there is a definite syndrome of slight cyanosis, increased aortic second sound, and increased blood pressure, that goes with many cases of intestinal stasis. Furthermore, I am certain that many persons leading a sedentary life can have daily bowel movements and still be constipated.

My argument is, that the systolic blood pressure is maintained by vasoconstricting substances in the circulating blood, and that an abnormally high blood pressure indicates that the blood stream contains either toxic substances (whether unexcreted products of metabolism or of focal purulent processes) or an excessive amount of the vasoconstricting secretion of particular glands of internal secretion. The functional test of cardiac efficiency suggested by the observation of Graupner[1] that when a man has been put through a certain amount of exercise, and when following this his pulse rate has returned to normal, his systolic blood pressure as a rule rises, would seem to me to be better explained by the theory that there was an increase in the amount of vasoconstricting internal secretion, liberated perhaps by the thyroid or suprarenal glands as a result of the increased circulation following exercise, rather than on the basis of the condition of the heart muscle.

In further support of this argument is the condition that one finds present in many cases of small-lunged emphysema, usually with chronic bronchitis and asthma. In many cases there is present a constant hypotension. Certainly some patients with severe bronchial asthma are much benefited by repeated administration of epinephrin. While as yet I have had no opportunity of working out my theory along this line, the known facts would seem to favor the existence in such asthmatics of a deficient secretion of vasoconstricting substances.

With regard to the meaning of the diastolic blood pressure, I feel that our present conceptions are even more wide of the mark. Observers in general feel that the diastolic pressure represents the power of the heart to maintain the circulation. In aortic regurgitation, in hyperthyroidism, and in "irritable heart of soldiers," we may have a greatly lowered diastolic pressure without necessarily any actual failure of the muscle power of the heart. Many clinicians feel that a diastolic pressure above 100 mm. indicates a myocardial defect. With this point of view I cannot agree. I believe, as do many others, that a systolic blood pressure of 150 or 160 mm. may be normal for a man 50 years old. To my mind, the ratio 2:3 for the diastolic and systolic pressures, respectively, should be maintained by the normal heart regardless of the rise or fall of pressure; and with a pressure of 160 mm. systolic, I believe that an intact circulation would show a diastolic pressure of from 105 to 110 mm. The relatively lowered diastolic pressure in thyrotoxicosis and in "effort syndrome" may perhaps be explained either as a vice of internal secretion, or perhaps in the case of "effort syndrome," as the result of intestinal stasis. In aortic regurgitation we may perhaps explain the low diastolic pressure as due to fatigue either of the vasoconstrictor centers or of the vasoconstrictor muscles. However, the explanation of the blood-pressure phenomena in aortic regurgitation seems more difficult than under the other conditions; it is a condition set off by itself, in which no rule seems to hold good. So far as any theory may be formed regarding aortic regurgitation, this condition helps merely to throw doubt on all other theories as to the significance and causation of changes in the diastolic pressure.

The more I study blood pressure, the less sure I become of any of the accepted interpretations regarding the test. Certainly, while I have as much respect for blood-pressure readings as ever, I feel that we must get a new conception as to the factors influencing the readings.

CONCLUSIONS

1. It is believed that increased systolic blood pressures indicate the presence in the circulating blood either of unexcreted putrefactive products absorbed from the intestine, from the kidneys, from focal infections in the dental alveoli, the nasal sinuses, the tonsils, the genito-urinary tract, or of secretions in abnormal amounts from the glands of internal secretion.

2. It is believed that in some cases at least, a lowered systolic blood pressure indicates a defective secretion of pressor substances, or an increased secretion of depressor substances by the ductless glands.

3. It is believed that the diastolic pressure, when it fails to conform to its normal ratio with the systolic pressure, is also influenced by abnormal products of metabolism or by abnormal amounts of ductless gland secretion in the blood stream.

4. It is not believed that either the systolic or the diastolic blood pressure gives any certain indication as to the condition of the cardiovascular renal system as such; and that when changes in the vascular system are accompanied by hypertension, neither condition is secondary to the other, both being held to be secondary to the presence of unexcreted toxic products of metabolism in the circulating blood.

483 Beacon Street.

A HOSPITAL EPIDEMIC OF STREPTOCOCCIC SORE THROAT WITH SURGICAL COMPLICATIONS

J. J. KEEGAN, M.D.
Lieutenant, M. C., U. S. Navy
CHELSEA, MASS.

The object of this report is to call attention to an unusual epidemic of throat infection in the surgical wards of a hospital, caused by a peculiar hemolytic streptococcus and sharply differentiated from the streptococcus bronchitis and bronchopneumonia which assumed epidemic proportions during the winter of 1917-1918 and has been present to a less extent during the winter of 1918-1919.

PREVIOUS EPIDEMICS

Streptococcic sore throat, septic sore throat, epidemic sore throat and milk-borne sore throat are terms used synonymously to denote the type of epidemic disease here described. The first description of a similar disease in the United States was that of an outbreak in eastern Massachusetts in May, 1911,[1] although in England writers had recognized and reported outbreaks previously.[2] Further outbreaks in the United States were reported from Chicago in December and January, 1911-1912,[3] and from Baltimore in February, 1912.[4] All of these epidemics were attributed to an infected milk supply, on fairly strong circumstantial evidence, and at the present time it seems to be generally accepted that this is the principal, if not the only, means of spread of this disease.

SURGICAL PROBLEM

The present epidemic at the U. S. Naval Hospital, Chelsea, Mass., first came to attention on account of the numerous instances of postoperative rise of temperature in clean surgical cases and the too frequent deep infection of the wounds with a peculiar hemolytic streptococcus. At first, operating-room infection was suspected, but cultures from the throats and the hands of the operating-room staff were negative for hemolytic streptococci, as were cultures from catgut and clean wounds before closure. Ward surface infection of the wounds was excluded because most of the infected cases had a primarily clean, well closed incision, and the operating-room dressing had not been touched before discovery of the infection.

More careful analysis of the surgical case histories showed that every case of wound infection with this peculiar hemolytic streptococcus was preceded for two, three or four days by a sore throat and a sudden rise of temperature, with normal or nearly normal temperature up to the time of the appearance of the wound symptoms. The throat infection occurred usually a day or two after operation, sometimes longer. The temperature became normal in a day or two. It was also noted that patients that entered the surgical wards for simple hernia or varicocele operation sometimes developed this sore throat and rise in temperature before operation. From the throats of these patients, the same peculiar hemolytic streptococcus was constantly recovered almost in pure culture on blood agar plates, as found later in the wound infection.

When, after all possible precautions had been taken to eliminate operating-room contamination, there was a continuance of wound infection in the surgical wards, it was concluded that it must be due to a metastatic blood infection from the primary pharyngeal and tonsillar lesion.

At the same time that infections were occurring in the general surgical wards, or even earlier, there was a similar difficulty in the nose and throat surgical wards. It seemed that fully half of the uncomplicated septum and tonsil operations were being followed in one or two days by a sudden rise of temperature associated with sore throat, or occasionally an erysipelas, sinus or ear infection. From these infections the same type of hemolytic streptococcus was recovered as found in the general surgical wards.

So serious had the situation become in the surgical service that all operations, except emergencies, were suspended, in order to investigate the cause and ascertain the means of control of the too frequent surgical complications caused by the hemolytic streptococcus. This investigation disclosed that there was a true epidemic of streptococcic sore throat in several of the wards of the hospital. The distribution of the cases was distinctinctly localized in wards which were related either to the primary acute throat wards or to the surgical wards, these being more particularly the influenza wards to which acute throat patients were sometimes admitted on undetermined diagnoses, and convalescent surgical wards fed from the surgical wards in which the epidemic was first recognized. In one convalescent surgical ward of about thirty patients, six new cases were found at one evening inspection, all presenting a rather serious condition with symptoms very suggestive of an outbreak of influenza, all of which patients later developed very severe and typical throats. In addition to these ward epidemics, several cases developed among the hospital corpsmen, both from the infected wards and from other wards, the latter being evident contacts with the former in the corpsmen quarters and tending to spread the epidemic over the entire hospital.

SYMPTOMS

The subjective symptoms of the most typical cases at the height of the epidemic were quite constant and severe. As accurately as could be determined, the period of incubation was two or three days, this judgment being based on the earliest cases developing in new men entering the hospital. Usually there were prodromal symptoms a few hours before the acute onset of the fever. These were an indefinite feeling of malaise and a loss of appetite, for which a laxative frequently was requested. The temperature was taken without showing any rise. Frequently during this period a beginning localization in the throat was noted —a slight dryness and soreness. The onset of fever was sudden and accompanied by alternating warm and chilly sensations, sometimes a distinct chill, dizziness, prostration, very severe frontal headache, a slight stiffness and soreness of the neck, and mild back, muscle and joint aching. Thus far the onset was typical only of the onset of any severe acute infectious disease, and particularly liable to be confused with influenza during an epidemic.

Within twelve hours, however, localizing symptoms appeared that clearly differentiated the disease from influenza. The throat became very sore so that swallowing was painful and there was a tendency to expectoration of mucus and saliva. Occasionally this sputum was blood-stained from pharyngeal hemorrhages. Very soon after the development of the throat symptoms, within one or two days from the onset, the systemic symptoms largely disappeared, with a coincident drop in the temperature, so that the patient felt fairly comfortable except for the fact that the throat remained very sore and swollen.

The objective localizing symptoms related entirely to the pharyngeal lesion. At the onset the throat was not characteristic. There was a general vascular injection of the lateral and posterior pharyngeal walls, sometimes described as a beefy red throat, with not much swelling or exudate. This condition gave the dry, slightly sore feeling noted, and can be found in the onset of almost every acute infectious disease. The tenderness at onset was usually more noticeable than in the onset of influenza, thus indicating early the site of the characteristic local lesion. Very rapidly, within twelve to twenty-four hours, this local lesion appeared. It consisted of a swollen, very dark red, lateral, pharyngeal and tonsillar region, with a beginning thin, grayish-white, slimy exudate over the crypts of the tonsils. In the absence or the fibrotic condition of the tonsils, the lymphoid tissue of the lateral, posterior and nasopharyngeal walls was involved, with less evident exudate. All grades of local lesion were present, from a simple injected pharynx with rapid return to normal, to an extremely swollen and painful condition of the tonsils, covered over entirely with a slimy, grayish membrane suggesting diphtheria, or the crypts and supratonsillar fossa may form foci of ulceration sometimes coalescing into large ulcers covered with a dirty, yellowish-white membrane very similar to the so-called Vincent's angina.

CLINICAL CHART AND BLOOD PICTURE

The temperature curve is not especially characteristic. In typical severe cases it mounts from normal to 104 F. within an hour or two, remaining high one or two days and returning to normal within a similar period. The recovery from systemic symptoms is even more rapid than the drop in the temperature, thus differentiating the disease from influenza. Another feature quite characteristic of this epidemic streptococcic sore throat is the frequent relapse or recurrence of symptoms and fever, occasionally two or more times, at intervals of from two to five days.

The leukocyte count is generally above normal, between 10,000 and 15,000. This is a valuable point of differentiation from influenza at the onset, for in influenza there is almost constantly a distinct leukopenia. However, this rule of differentiation is not absolute, for occasionally at the onset of toxic symptoms of streptococcic sore throat there is a distinct leukopenia, total leukocyte counts as low as 4,000 being obtained. This is quickly followed by the characteristic moderate leukocytosis with no significant variation of the differential count from normal. This primary leukopenia may be of more constant occurrence than is disclosed by routine leukocyte counts on these patients, for it is rare to obtain a count before the secondary throat lesion is well advanced. The interpretation of this initial leukopenia is that it represents a bacterial anaphylactic reaction from the increasing local or general destruction of streptococci. The primary symptoms of onset are indistinguishable from those of a great number of acute infectious diseases. The specific and characteristic reaction of streptococcic sore throat, as of all acute infectious diseases, is dependent on the nature and site of the local process developing subsequent to and as a result of the primary bacterial anaphylactic reaction. In streptococcic sore throat the secondary lesion is located in the pharyngeal and tonsillar lymphoid tissue. The primary site of invasion is in all probability in the same region.

BACTERIOLOGIC FINDINGS

The hemolytic streptococcus constantly recovered, almost in pure culture from these sore throats, and in pure culture from the surgical infections under discussion, had definite unusual cultural characteristics. The colonies on the surface of blood agar (10 per cent. defibrinated sheep's blood in plain agar) were large and moist, having the clear appearance of a drop of water, or with a slightly opaque or cloudy center as drying proceeded. The hemolysis was not marked, nor was there a sharply defined outer border, this extending very little beyond the outer border of the colony at the end of twenty-four hours' growth. In the first culture from two or three cases of wound infection and from a few very severe throats there was little or no hemolysis at the end of twenty-four hours, the growth appearing merely as perfectly clear droplets of water with a tendency to confluence. Longer growth and subcultures from these showed a more distinct hemolysis and less moist colonies. On drying, these moist colonies flattened out to a thin layer on the surface of the blood agar, sometimes showing radial lines or concentric rings.

Cultures in glucose bouillon gave at first a uniform turbidity, but within forty-eight hours there was noted a tendency of the growth to accumulate at the sides and bottom of the test tube, with final settling and partial clearing of the supernatant fluid.

Smears from the throat showed numerous pus cells and flattened or spherical gram-positive diplococci with few chains of more than two or three diplococci. Capsule stain gave a suggestion of a narrow capsule, but not more than can be obtained on numerous organisms in an albuminous exudate. Smears from the moist colonies on blood agar showed large spheric, gram-positive diplococci in short chains. The capsule stain gave no definite capsule, but a wide albuminous envelop of greater density near the diplococcus. In bouillon cultures, short chains were formed. These streptococci were not soluble in bile, and did not ferment inulin or mannite in Hiss' serum water mediums. They gave a distinct acid reaction in glucose, maltose and galactose, a slightly acid reaction in lactose, and a questionably acid reaction in saccharose and dextrin. Coagulation occurred in none of the tubes after ten days' growth. They differed from the ordinary *Streptococcus pyogenes* and the lung streptococci only in cultural characteristics, the latter growing in smaller, dry, white, granular colonies on blood agar, and in bouillon as a flocculent sediment forming long chains.

This description of the hemolytic streptococcus found in this epidemic of sore throat appears to agree in every way with that of the writers previously referred to in studies of earlier epidemics.

In several cases of streptococcic sort throat developing in the hospital, throat cultures were taken the day preceding the onset of toxic symptoms, with negative results for hemolytic streptococci. In a few cases, throat cultures taken at the onset of symptoms were negative, with typical positive cultures obtained on succeeding days. One case in particular deserves special description to indicate the possibility of typical toxic symptoms and positive throat culture but with negative throat symptoms:

A routine throat culture of a convalescent patient ready to go to duty was taken, March 3, and was negative for hemolytic streptococci. On the evening of March 4, he felt a little indisposed, with no rise of temperature. The following morning at 8 o'clock he felt distinctly ill, with slight headache; but the temperature was still normal. At 10 a. m. he had a sudden, fairly severe chill, with sweating, prostration and very severe frontal headache, but no other aches nor pains and no discomfort nor symptoms in the nose or throat. The pharyngeal wall appeared injected, but there was no exudate. A few blood clots were blown out of the nose. The temperature by noon was 104 F.; leukocyte count, 5,000. Throat culture taken in the afternoon gave a pure growth of the characteristic moist hemolytic streptococcus. At no time was there any throat pain or discomfort, or any exudate. A mild relapse occurred four days later.

Blood cultures were taken in ten cases at various periods of the infection from the onset to five days following, with negative results. It is well established, however, from previous, more severe epidemics, that there is frequently, if not constantly, a blood invasion by the streptococci from the throat. Clinically this has been evidenced by the complications, such as arthritis, endocarditis, purpura and spontaneous peritonitis, that have occurred in cases. Thus in 173 typical cases of the Chicago epidemic,[5] there were seventeen cases of arthritis, three of purpura, five cases of endocarditis, and nine cases of idiopathic peritonitis. Davis and Rosenow[3] state that blood cultures are almost always negative when glandular enlargement is pronounced, but that streptococci may be recovered at the outset of such cases. Also, it has been noted by numerous writers that visceral complications occur most often in the group of cases that have little or no glandular involvement but marked constitutional disturbance.

---

[5] Capps, J. A., and Miller, J. L. (Footnote 3).

The evidence of a bacteremia in the cases of the Naval Hospital epidemic, although not furnished by blood cultures, could hardly be more strikingly indicated than by the frequent deep infection of the traumatized tissue of abdominal surgical wounds with the characteristic hemolytic streptococcus, following a similar throat infection of often very mild character.

COMPLICATIONS

The chief and almost constant complication of this epidemic of streptococcic sore throat was tenderness and swelling of the submaxillary and cervical lymph glands. There was no case of suppuration except a peritonsillar abscess in a considerable number of cases. Middle ear and mastoid infection occurred as a direct sequel in six cases, a facial erysipelas in three. An acute arthritis of mild type with no suppuration was present in a few cases.

Relapses, with fever and typical throat lesion, were quite common; in fact, almost characteristic of this disease. They occurred usually three or four days after the complete subsidence of fever and of local symptoms, although positive throat cultures remained.

Deep infection of the surgical wounds was the most alarming complication. This has been discussed in preceding paragraphs.

A most noteworthy feature of the complications was the entire absence of any symptoms of bronchitis or bronchopneumonia in over 100 cases observed. There seemed to be no tendency of the infection to extend below the pharynx, even hoarseness rarely occurring. This fact is significant on account of the frequent statement and the general impression that streptococcus bronchitis and bronchopneumonia begin as a throat infection. At the same time that these cases of streptococcic sore throat were being studied, typical cases of streptococcus bronchitis and bronchopneumonia were being received in the pneumonia wards and almost universally gave a negative history and negative physical findings of a primary throat lesion, the only history obtained being a slight dry or sore feeling usually attributed to coughing. These facts indicate a distinct property of specific primary localization of strains of the hemolytic streptococcus, differentiated with difficulty by cultural or morphologic characteristics, in the one case in the throat with complications related to the adjoining sinuses and lymph glands, in the other case in the bronchi with complications related to the lungs and pleura.

Culturally, morphologically, and by the fermentation reactions these two types of streptococci can be differentiated only by the peculiar moist appearance of the blood agar colonies of the throat streptococci during an epidemic of sore throat. The same characteristics are present to some extent with the lung streptococci in primary cultures, these showing large, moist colonies and the formation of capsular substance in tissue mediums. These particular cultural qualities have been recognized by many writers in relation to these and other pathogenic micro-organisms and have been interpreted as indicating a heightened virulence of the micro-organism, produced by rapid transmission from animal to animal. In repeated subcultures, neither the throat streptococcus nor the lung streptococcus can be differentiated from the ordinary *Streptococcus pyogenes*. Immunity reactions in the hands of other investigators have been little more instructive. However, the distinct characteristics of unusual infectiveness and of specific primary localization of the epidemic throat streptococci and of the epidemic bronchopneumonia streptococci indicate fundamental principles controlling acute infectious diseases.

EPIDEMIOLOGY

From the preceding description I do not believe there can be any doubt that this epidemic of sore throat was identical clinically, pathologically and bacteriologically with the streptococcic sore throat epidemics of 1911 and 1912 in Boston, Chicago and Baltimore. On account of the generally accepted idea that milk contamination was the chief, if not the only, source of infection in these and similar epidemics in the past, it is necessary to analyze the situation at the U. S. Naval Hospital for the possibility of such a source.

The milk supply to the Naval Hospital during the epidemic has been from the Hood's dairy, which supplies all parts of Boston and adjoining cities and is one of the largest and most modern in this section of the country. The milk received at the Naval Hospital is issued to every ward and given to all patients. There are twenty-seven wards averaging thirty beds each, making the census of the hospital about 800. A milk-borne infection would be expected to appear simultaneously in every ward, but this was not the case. The first wards infected were the nose and throat surgical wards and the general surgical wards, all situated in the main permanent brick building. The infection in the nose and throat wards really preceded that in the general surgical wards. The second focus of infection was in the throat infectious wards into which throat patients were entering from the outside and were being transferred from the surgical wards. The next wards infected were the influenza wards, which frequently received early throat cases with undetermined diagnoses, and the convalescent surgical wards, recruiting from the infected surgical wards. All other wards in the hospital were free from throat infection at this time, three weeks after the onset of the epidemic, during which time more than fifty recognized cases had developed. Among these were several hospital corpsmen on duty in the infected wards. From them the epidemic spread to the corpsmen quarters, and from this focus of infection cases began to appear, one or two at a time, in various wards throughout the hospital, and is continuing at the present time in this manner. Several physicians and nurses have contracted the disease.

This manner of spread of the infection indicates contact infection and strongly opposes the idea of milk as the carrier in this epidemic. Cultures of the milk revealed no hemolytic streptococci. The simplest and least artificial explanation of the spread of such an epidemic disease is by contact with infected cases. This is supported by the experimental transmission of the characteristic streptococcic sore throat to volunteers during experiments in the transmission of influenza conducted by the Navy and the Public Health

Departments at Gallops Island, Boston Harbor. This was effected by the direct transfer of throat exudate from patient to volunteer.

The factors determining the infectiveness of a microorganism in an acute infectious disease are very poorly understood, but it is certain that the mere presence of the hemolytic streptococcus in the throat does not necessarily mean that the case is infective. The infectiveness or virulence in epidemic disease is more probably determined by a combination of anaphylatoxin and pathogenic micro-organisms in the droplet or other vehicle of transmission, to make possible the infection from such a small quantity of material. This has recently been emphasized by Rous, Robertson and Oliver,[6] who found, in trying to develop an antipneumococcus serum in dogs by using an infected tissue antigen, that dogs, although quite resistant to pneumococcus broth cultures extremely virulent to mice, succumbed to a very small amount of tissue or blood from a rabbit in the terminal stages of pneumococcus septicemia.

An analysis of the evidence brought forth in 1911-1912, generally accepted as proving that epidemic streptococcic sore throat is milk-borne, shows that the conclusions were considerably overdrawn and have excluded a considerable amount of evidence which would indicate otherwise. For example, in the Boston epidemic,[1] although circumstantial evidence of milk transmission is fairly conclusive in regard to the epidemics of Back Bay and Cambridge, it is less conclusive in regard to the epidemic of Brookline, and fails completely to explain the epidemics in Hudson, Marlboro and Southboro. Thobald Smith,[7] in a later analysis of seven small epidemics in the region of Boston and investigation of the milk supply supposed to have caused these epidemics, recovered in only one instance in milk a streptococcus comparable to those found in the epidemic, and this from the three normal udders of a cow that had one infected udder. In Chicago,[5] the epidemiologic evidence was more complete, yet milk contamination does not explain satistorily the increase of virulence of a common microorganism until it is capable of causing severe anaphylactic symptoms and metastatic invasion in the human body. This increase of virulence must have been effected by rapid repeated human transmission, and is hardly conceivable by any form of mastitis in the cow, which would tend to decrease the virulence of a microorganism as specific in its manifestations as the hemolytic streptococcus of epidemic sore throat. The evidence of milk contamination in the Baltimore epidemic[4] was very meager, hardly more than a supposition seized on by public health authorities to pacify an agitated public.

A complete explanation of the epidemiology of this disease is still lacking. Milk contaminated by an acute case on the morning of its distribution may be a contributing source of some localized epidemics, but the burden of proof certainly rests with those who would be satisfied with this explanation of all epidemics. The claim that such a common carrier as milk or water is necessary to explain the explosive nature of such outbreaks of epidemic disease is reasoning from an unestablished premise and is less easily accepted since our recent experience with influenza. The means of rapid spread in a community of a virus which has become extremely infective are so manifold by direct contact of individuals in present day society that it is rarely possible to have any idea of the source of infection from such ambulatory diseases as influenza and streptococcic sore throat.

MEANS OF CONTROL

An epidemic infection of streptococcic sore throat in surgical wards, with metastatic invasion of operation wounds, becomes a much more serious and urgent problem for control than an epidemic of sore throat in a civil community. Immediately on recognition of the serious surgical condition present, all operating, excepting emergency cases, was discontinued and a survey of the surgical wards was made to discover acute cases and carriers of the hemolytic streptococcus, particularly the moist or mucoid hemolytic streptococcus characteristic of this epidemic sore throat. An occasional case of sore throat had been noted previously in the nurses and corpsmen on duty in the surgical wards, for which they had been off duty a day or two, or in some cases not at all. In the surgical wards, numerous carriers of the characteristic moist hemolytic streptocuccus were found; for example, in one ward there were five carriers among two nurses and seven corpsmen, with three additional carriers of the ordinary hemolytic *Streptococcus pyogenes*.

These carriers of hemolytic streptococci were all removed from the surgical service; all throats were observed frequently, and cultures were taken on the least complaint or on the appearance of physical signs. When a new throat case developed among the patients in the wards, the patient was immediately isolated and removed from the ward, if possible. A so-called clean ward was established and most carefully controlled, including all new cases entering the hospital for operation.

After about three weeks' discontinuance of operating, work was resumed again, the control of physicians, nurses, corpsmen and patients for hemolytic streptococci being, however, continued. For a time operations were not performed on any patient showing hemolytic streptococci in the throat on entrance. Later this rule included only those showing the moist colonies. No more postoperative streptococcus infections have occurred, although there are still occasional cases of this characteristic streptococcic sore throat occurring in corpsmen and patients throughout the hospital. Also many new cases have been admitted to the throat wards from outside stations, which shows that the infection is widely spread over the district.

CONCLUSIONS

1. An epidemic of hemolytic streptococcic sore throat has prevailed during February, 1919, at the U. S. Naval Hospital, Chelsea, Mass.

2. This epidemic infection has been comparable in clinical, pathologic and bacteriologic findings with the epidemics of streptococcic sore throat reported in Boston, Chicago and Baltimore in 1911 and 1912.

3. Attention was first called to the presence of an epidemic at the Naval Hospital by the numerous instances of postoperative rise in temperatures in surgical cases, associated with sore throat, and subsequent infection of the primarily clean surgical wounds with a peculiar hemolytic streptococcus.

6. Rous, Peyton; Robertson, O. H., and Oliver, J.: Experiments on the Production of Specific Antisera for Infections of Unknown Cause, I, Type Experiments with Known Antigen, J. Exper. M. **29**: 283, 1919.

7. Smith, Theobald, and Brown, J. H.: A Study of Streptococci Isolated from Certain Presumably Milk-Borne Epidemics of Tonsillitis, J. M. Res. **21**: 455, 1914.

4. The symptoms of onset of the sore throat were characteristic of acute bacterial anaphylaxis—sudden chilliness, dizziness, fever, headache, backache, general aching and prostration, with occasionally an initial leukopenia.

5. The secondary symptoms localized in the tonsils or lateral pharyngeal walls, with complications referable to the submaxillary and deep cervical lymph glands, the nasal sinuses, the middle ear and mastoid, the face, and by metastatic infection to the surgical wounds and the joints. In no case was there a complicating bronchitis or bronchopneumonia. This stage of the disease was constantly associated with a moderate leukocytosis.

6. The micro-organism constantly recovered in almost pure culture from the throat and the infected wounds was a hemolytic streptococcus, growing in large, moist, droplet-like colonies on blood agar mediums.

7. The hospital epidemic originated in the nose and throat surgical wards, from which it spread by contact to other wards. There was practically no possibility of spread by milk contamination.

8. Control of the epidemic was effected by suspension of all operating for a period of three weeks, immediate isolation of all acute throat cases, and elimination from the surgical service of all carriers of hemolytic streptococci.

AN OLD TIME VICTIM OF AMETROPIA AND A MODERN INSTANCE

E. J. GARDINER, A.B., M.D.
CHICAGO

There are numerous references in general literature to instances in which eye affections have hampered distinguished persons in the performance of their labors. Most of these references are to be found in biographies, but, so far as I know, there are few instances of the person afflicted having written an account of his symptoms that would enable an oculist to make a diagnosis, and to prescribe with a reasonable degree of accuracy the remedy that would have restored the patient's eyes to usefulness.

The most interesting case of this kind is in Samuel Pepys' famous Diary. It is generally known that this unique document came to a premature end when its author was but 36 years old, and that the cause that forced him to give up this work was that his eyes gave out completely for close work. But it is known only to attentive readers of the Diary that so detailed is the description of his symptoms that a diagnosis can be made and a good guess ventured as to the remedy that would have enabled him to continue his work.

The story of Pepys' sufferings, as recorded in the Diary, has been so well edited by Mr. D'Arcy Power that I shall quote freely from his article published in Volume I of "Occasional Papers Read by Members of the Samuel Pepys Club, 1903-14." Indeed I have found it quite necessary to make use of Mr. Power's quotations, for a number of them are not contained in my ten volume edition of the Diary, published by Dodd-Mead and Company, 1889.

The first record of any complaint about his eyes is made by Mr. Pepys on Jan. 19, 1663-1664, when he was nearly 30 years old, and had been rather worried by an unreasonable jealousy of his wife. He writes: "I to my office till very late, and be in pain which I never felt to now-adays, which I impute to sitting up late writing and reading by candle-light." Again, on April 1, 1664, he complains: "This day Mrs. Turner did lend me a manuscript of one Mr. Wells, writ long ago, teaching the method of building a ship, which pleases me mightily. I was at it tonight, but durst not stay long at it, I being come to have a great pain and water in my eyes after candle-light." On May 4: "So home to dinner, and after dinner to my office very late till my eyes (which begin to fail me now-adays by candle-light) begin to trouble me." And on the following day: " . . . to the office . . . and thence betimes home. my eyes beginning every day to grow less and less able to bear long reading or writing, though it be by daylight; which I never observed till now." On Oct. 5, 1664, he set about getting some assistance for his sight, for, " . . . then comes Mr, Croker to see me, and I discoursed with him about his writing and ability of sight and how I shall do to get some glasses or other to help my eyes by candle-light; and he tells me he will bringe the helps he hath within a day or two, and show me what he do."

On October 11, there is a memorandum to the effect that: "I had taken my Journal during the fire and the disturbing following in loose papers until this very day, and could not get time to enter them in my book till January 18, in the morning, having made my eyes sore by frequent attempts this winter to do it." On Dec. 13, 1666: " . . . for these three or four days I perceive my overworking of my eyes by candle-light do hurt them as it did last winter, that by day I am well and do get them right, but then after candle-light they begin to be sore and run, so that I intend to get some green spectacles." Three days later: " . . . home by water, and to supper and to read and so to bed, my eyes being better today, and I can not impute it to anything but my being much in the dark tonight, for I plainly find that it is only excess of light that makes my eyes sore." On Christmas eve, he writes: "I do truly find that I have overwrought my eyes, so that now they are become weak and apt to be tired, and all excess of light makes them sore, so that to candle-light I am forced to sit by," adding, "the snow upon the ground all day, my eyes are very bad, and will be worse if not helped, so my Lord Bruncker do advise as a certain cure to use greene spectacles, which I do." Later on the same day: "I this evening did buy me a pair. of green spectacles, to see whether they will help my eyes or no. . . . Then home, to my office, and did business till my eyes began to be bad and so home to supper." On New Year's eve he was busy with his accounts, "till my eyes became very sore and ill, and then did give over, and supper and to bed."

Pepys does not again complain of his eyes until April 12, 1667, when: "I close my office all the afternoon getting off of hand my papers which, by the late hollidays and my laziness were grown too many upon my hands, to my great trouble. and therefore at it as late as my eyes would give me leave." April 22: " . . . did business till my eyes were sore again, so home to sing, and to bed, my eyes failing me mightily."

Aug. 3, 1667: " . . . my eyes began to fail me, which now upon very little overworking them they do, which grieves me much." Sunday, August 4: "Busy at my office from morning till night in writing with my own hand fair our large general account of the expense and debt of the Navy, which lasted me until night to do, that I was almost blind." August 19: "I home to supper and to read a little (which I cannot refrain, although I have every reason in the world to favour my eyes, which every day grow worse and worse, by overusing them.") Sept. 4: "At business till twelve at night writing in short hand the draught of a report to make to the King and Council tomorrow. . . . This did finish tonight to the spoiling of my eyes I fear." The next day: "My eyes so bad since last night's straining of them that I am hardly able to see, besides the pain which I have in them."

At the beginning of this winter Pepys took some trouble to get his defective sight improved, for on November 4: "I took a coach and went to Turlington. the great spectacle maker, for advice, who disuades me from using old spectacles. but rather young ones, and so tell me that nothing can wrong my eyes more than for me to use reading glasses which do magnify much." Mr. Turlington's advice was superlatively wrong, for he was clearly recommending Pepys to use concave glasses when in reality he needed convex ones. It is probable that the spectacles were tried and found unsuitable, for he never bought them, and on the 14th, he writes: "So home to supper and to bed, my eyes being bad again; and by this means the nights nowadays do become very long to me, longer than I can sleep out." In his survey of April, 1668, he says that he is in "some trouble for my friends . . . and more for my eyes, which are daily worse and worse that I dare not read almost anything."

We read no more about the state of Mr. Pepys' eyes for the next six months, until June 20, 1668, when there is an entry: "So we home and there able to do nothing by candlelight, my eyes being now constantly so bad that I must take present advice or be blind. So to supper and to bed." His eyes must have been more than usually painful at this time, for on June 29, nine days later, he writes: " . . . towards St. James', and I stop at Dr. Turberville's and there did receive a direction for some physic, and also a glass of something to drop in my eyes; who gives me hopes that I may do well." On the following day: "Supper about eleven at night; and so after supper, parted, and to bed, my eyes bad, but not worse, only weary with working. But, however, I very melancholy under the fact of my eyes being spoiled and not recovered; for I am come to that I am not able to read out a small letter, and yet my sight good for a little while I can read, as ever they were I think." On July 13: "This morning I was let blood, and did bleed about fourteen ounces, towards curing my eyes." July 31: "The month ends mighty sad with me, my eyes being now past all use almost; and I am mighty hot upon trying the late printed experiment of paper tubes." His eyes were so bad at this time that he made his boy (August 2) "read to me several things, being unable nowadays to read myself anything above two lines together, but my eyes grow weary." August 11 " . . . at the office all the afternoon till night, being mightily pleased with a little trial I have made of the use of a tube-spectacal of paper, tried with my right eye." The result of the trial must have been satisfactory, for on the 12th he went to the play and saw "Macbeth," and "then home, where the women went to making my tubes." But the improvement was not long maintained, as on the 15th: "So home and to my business at the office my eyes bad again, and so to bed."

Feb. 16, 1668-1669: " . . . my eyes mighty bad with the light of the candles last night, which was so great as to make my eyes sore all this day, and do teach me a manifest experiment that it is only too much light that do make my eyes sore. Nevertheless, with the help of my tube and being desirous of easing my mind of five or six days journal, I did venture to write it down from ever since this day se'nnight, and think that without hurting my eyes any more than they were before, which was very much, and so home to supper and to bed . . . ." Even at the play house in a good place among the ladies of honour he "was in mighty pain to defend myself from the light of the candles."

From his thirty-sixth birthday onwards the complaints about his eyes become even more frequent and always in the same strain . . . and they were so painful on many occasions that he was obliged to curtail even his play-going.

Some extra work that he did the latter part of March led him to make another attempt to get relief, for on April 29: "Up and to my office awhile and thither comes Lead with my vizard, with a tube fastened within both eyes; which with the help which he prompts me to, of a glass in the tube, do content me mightily, and then . . . he being gone, to write down my journal for the last twelve days; and did it with the help of my vizard, the tube being fixed to it, and do find it mighty manageable, but how helpful to my eyes this trial will show me."

Pepys had the tubes altered with his usual ingenuity, for on May 8, 1669: "Up to the office and there comes Lead to me and at last my vizards are done and the glasses got to put in and out as I will; and I think that I have brought it to the utmost, both for easiness of using and benefit, that I can; so I paid him 15s. for what he hath done now last in finishing them, and they I hope will do me a great deal of ease. At the office all this morning and this day the first time did altar my side of the table after eight years sitting on that next the fire. But now I am not able to bear the light of the windows in my eyes . . . ."

The vizard and the change of position proved of small use, however, for on May 16, 1669: "Dined at home . . . and I all the afternoon drawing up a foul draught of my petition the Duke of York about my eyes for leave to spend three or four months out of the office, drawing so as to give occasion to a voyage abroad, which I did to my pretty good liking."

Having obtained his leave, he spent the remaining days of the month in making preparations for the holiday, and the Diary ends on May 31, 1669.

> And thus ends all that I doubt I shall ever be able to do with my own eyes in the keeping of my Journal, I being not able to do it any longer, having done it now so long as to undo my eyes almost every time that I take a pen in my hand; and therefore what ever comes of it I must forbear; and therefore resolve, from this time forward, to have it kept by my people in long-hand, and must therefore be contented to set down no more than is fit for them and all the world to know; or, if there be anything, which cannot be much now my amours to Deb. are past and my eyes hindering me almost all other pleasures. I must endeavor to keep a margin in my book open, to add here and there a note in shorthand with my own hand. And so I betake myself to that course which is almost as much as to see myself go into my grave; for which and all the discomforts that will accompany my being blind, the good God prepare me.

This pathetic renunciation was written just two hundred and fifty years ago. To the oculist of today it is clearly evident that Pepys' dread of blindness was unfounded, as he discovered in the course of his long life. Had his sufferings been due to simple hypermetropia it is pretty certain that in the many trials of glasses that he made, some lens should have corrected this defect and relieved his asthenopia, but no such relief is recorded. Therefore, it is logical to conclude that an additional astigmatic error was responsible for the continuance of the trouble. As astigmatism was not known until nearly two hundred years later, poor Pepys' case was quite hopeless and he had to give up his Diary. Thus it happened that an error of refraction deprived the world of an untold number of literary and historical contributions that would have been of inestimable value.

Mr. Power, after consulting with some of his confrères, comes to the conclusion that the lenses that would have corrected Pepys' ametropia are, +2 D. sph+0.50 D. cyl, ax 90. These lenses he had ground and mounted in a silver spectacle frame modeled on one that came to America in the *Mayflower* in 1620.

Now two hundred and odd years later comes a "modern instance." In August, 1893, Mr. J. R. from Boston consulted me regarding an asthenopia of long standing. He gave the following history: His eyes had given him trouble from the time that he started in school. At first he was troubled only when using them by artificial light, but they gradually grew worse until at times he was unable to study even by daylight. He had severe eye pains and headaches and had to be taken out of school two or three times a year. The work of preparing for college entrance examinations completely prostrated him, and he was sent to recuperate in Europe for six months. The profession that he had chosen was civil engineering, and he had set his heart on entering the Massachusetts

Institute of Technology, before his nineteenth year. As he had already lost over one year in preparatory school, this additional setback was a great disappointment.

When his eyes began to trouble him he was taken to an oculist who prescribed glasses and advised complete rest from close work. While in Europe, he saw an oculist who prescribed stronger glasses and told him to engage in some business that would not require hard work with his eyes.

Much improved by rest and change of climate, he returned to Boston and commenced the study of civil engineering. His eyes soon began to give him trouble and in two months he was obliged to take another rest. He managed, however, to get through the first year, and after three months' vacation in France, he started on his second year, soon broke down, and finally renounced his cherished ambition of becoming an engineer. His father was a merchant, and although Mr. R. disliked a commercial career, he was obliged to go into business and for the last ten years has been at the head of his father's establishment. But, he has never been able to use his eyes for close work.

When I read Mr. Power's interesting article, Mr. R.'s case came vividly to my mind. For not only were the symptoms and the error of refraction in both cases much alike, but the circumstances that in both instances prevented a proper correction of the ametropia were analogous and the final renunciations were the direct outcome of these circumstances.

Mr. R. had 2 diopters of hypermetropia in each eye and was wearing for distance +2 D. sph, with which his vision was 20/20 —. For reading he was wearing +2.75 D. When in the process of testing his eyes, having found that I could not improve on his +2 D. with any spherical lenses, I started to try cylindrical lenses, Mr. R. remarked that cylinders had been tried before, but that he never had been able to see so well with them. As it turned out +0.50 cyl did make matters worse, but +0.25 cyl added to the +2 D. sph, R. E. ax 120, L. E. ax 45, brought the vision up to full 20/20.

The last test that Mr. R. had for distance glasses was made in 1871 or 1872, and as at that time the test cases contained no quarter diopter cylinders, his astigmatism was not discovered, and consequently his asthenopia continued unabated. Why, when he was tested for reading glasses in 1889, the error was not detected I can not understand, for there was no uncertainty about the improvement in vision when the cylinder was put in place.

I did not see Mr. R. after my work was finished, but two months later I received a letter from him in which, after informing me that he was using his eyes with perfect comfort and that he spent his evenings "devouring" books that he had been unable to read in the past, he ended his letter with this sentence: "It is truly tantalizing to realize at my age that my life has been ruined and all my ambitions shattered by an astigmatic error of a quarter of a diopter."

Destroying the Fly.—As 99 per cent. of flies are bred in horse manure, the proper care of horse stables means fly extinction. Although the house-fly is the chief carrier of typhoid germs, the little fruit-fly, genus *Drosophila*, which usually breeds in overripe or decaying fruit may breed in human excrement and therefore should be guarded against.—U. S. Department of Agriculture. Farmers' Bulletin, No. 153, Washington, 1908, p. 16.

NARCOTIC DRUG ADDICTION AS REGULATED BY A STATE DEPARTMENT OF HEALTH

THOMAS S. BLAIR, M.D.
Chief, Bureau of Drug Control, Pennsylvania Department of Health
HARRISBURG, PA.

By an act of the Pennsylvania General Assembly, session of 1917, concurrently with the United States Congress, the Harrison Narcotic Law, to all intents and purposes, was placed on the statute books of the commonwealth. Under the police power of the state, the department of health regulates the possession, etc., of certain narcotic drugs now under the control of the United States Bureau of Internal Revenue as relates to interstate commerce. But special provisos in the Pennsylvania act make it unlawful to supply the named drugs in any quantity whatsoever to known habitual users thereof, except in pursuance of a prescription of a duly licensed physician or dentist, and physicians may, under proper regulations, and after a physical examination of an addict and a report in writing, take addicts under treatment, in good faith, for the purpose of curing the habit, and not merely for the purpose of satisfying a craving for the drug.

Section 5 of the Pennsylvania act prohibits administration of these drugs to any person except under the advice and direction, and with the consent, of a duly licensed physician or dentist; but a dentist may not treat an addict.

Records must be kept of administration except in an emergency case. Inspections and reports are provided for, as directed by the commissioner of health. Licenses of physicians and others may be suspended and revoked on conviction of violation of the act or for being a drug addict. Veterinarians may not supply the named drugs for the use of a human being, but may administer them to an animal which has been regularly examined and is under their care.

The commissioner of health was authorized to establish, in the department of health, a bureau or division for the purpose of enforcing the provisions of the act, to require reports to the bureau, and, under the powers conferred on him, to issue rulings and orders necessary for enforcement.

Under the provisions of the act, the bureau of drug control has been created, and, by means of monthly reports covering all purchases of narcotics by physicians and other professional persons, statements from all registered retail druggists of every prescription carrying material quantities of narcotic drugs and giving the names of the patients and physicians, registration of addicts, inspections, police investigations, detective work, and a clinical study of addicts themselves—all followed up intensively in a "This Means You" campaign—is accumulating dependable data which justify some comment.

From the pharmacologic point of view, physicians commonly fail to differentiate between narcotism and narcosis. Narcotism is stupor due to narcotics, while narcosis is the aggregate of influence or effect from continued use of narcotic substances. The latter constitutes a syndrome, a more or less permanent toxication, which is relieved only by renewed intoxicating doses of the enslaving drug, which, in turn, continue the narcosis or toxication, and so on indefinitely. While drug addiction may be considered as a vice, a disease, a habit; while it may be viewed sociologically, criminologically or psychically, it is, at base, a prolonged toxication. The other matters are incidental, serious though they may be.

Many physicians who have chronic or painful conditions to meet in practice, and who prescribe narcotics for relief, do not seem to realize the danger of addiction, and the fact that the final state of the addict with disease is more aggravated than if narcotics were never prescribed or were used most sparingly. The result is that about one half of the addicts reported to us are diseased persons. We consider them victims of poor therapeutics.

Sporadic, half-way measures of repression are a failure, for commercial effort steps in and offsets all the good done, and peddling of drugs, "underground traffic," and illicit professional use become aggravated by such measures. Only by a sustained and every-day effort, constantly followed up, is good accomplished. General propaganda, while useful incidentally, does not reach the persons involved, and serves only to attract attention to evils that are soon forgotten unless it is the daily business of certain capable people to ferret them out.

We find it necessary to give as much attention to the village as to the large city, for we find that, as to relative population, there is more free and unrestrained addiction in the small places than in the large cities. The larger number of our bad reports come from communities of from 3,000 to 30,000 population, many of them within easy reach of large centers of population. But this statement must be qualified by the further one that in the slums and vice districts of the cities may be found the largest pro-rata indulgence in drugs, although the vicious population is relatively small, even in the larger places. Furthermore, the federal authorities, and some city police departments—by no means all of them—exercise a large measure of control in the cities, while the addicts in small places, and outsiders going there for supplies, have rather free rein.

SOURCES OF SUPPLY

So far as we have been able to ascertain, prescriptions by physicians constitute the main source of supply by addicts, that is, taking the state at large. Much of this catering to the addict is unconscious on the part of the average physician, for there is always a plausible excuse offered, and the physician is unaware of the fact, as shown by our records, that most of these addicts visit several physicians. When we inform the physicians by mail of the facts in the cases, most of them are astonished; they have yet to learn the psychology of the addict. Then, there are many physicians of ready sympathy who think that the laws are oppressive and who forget that addicts lie; these physicians are exploited most shamelessly.

Smuggling is probably the next largest source of supply; but of this matter we have little exact knowledge, since its elimination lies within the province of the federal authorities.

Physicians prescribe narcotics for plausible strangers, who get the prescriptions filled, and it is common to find forgeries presented soon after. Many forged prescriptions are collected in our work. Recently, at our instance, a woman was arrested for forging twenty-six prescriptions and thus illegally coming into possession of narcotics; and yet five physicians were writing prescriptions for her. Two of them wrote on scraps of paper with pencil. These she found easy to be forged.

Some forgers steal pads of prescription blanks from physicians and druggists; sometimes they steal the drugs themselves, or get confederates to do so. We apprehended two of these men, but had to release them because the physicians would not appear against them. Such tactics simply encourage such thefts and discourage the police. Many physicians write prescriptions so illegibly that they cannot themselves tell the genuine from the forgeries.

Some physicians order their drugs from supply houses that shade the price and sell short weight. The possibilities here are immense as regards narcotic drugs.

Physicians write many prescriptions for preparations exempt under the provisions of the Harrison law, more especially for paregoric. Thousands of prescriptions for paregoric are written by Pennsylvania physicians for use by adults, despite the fact that the ordinary use for this preparation is in treating children. The Harrison law does not interdict its sale, and many druggists sell it freely. Most druggists realize that frequent purchase of paregoric in quantity means that the purchaser is an addict who wants both opium and alcohol. One druggist, with a store fronting the University of Pennsylvania, sold more than 2 gallons of it in the month of March. We ordered him to cease such sales, as they are against our regulations.

NARCOTIC DRUGS MOST FREQUENTLY PRESCRIBED

The federal-law-exempt National Formulary elixirs of terpin hydrate and codein, and terpin hydrate and heroin, as well as the host of similar proprietary preparations, are the "best sellers" in the narcotic field, so far as our records in Pennsylvania show, and this was especially the case during the influenza epidemic. Some people take to tippling with codein and heroin on their own account.

Codein is the narcotic appearing most frequently on the reports, morphin next, and then preparations of opium, followed by heroin and others. Cocain prescribing is becoming relatively infrequent. Codein, however, is rarely prescribed in excessive dosage, whereas heroin is very frequently so prescribed, especially in Philadelphia. There lies on my desk, just received, a report from a small drug store on South Eleventh Street, Philadelphia, noting fifty-six prescriptions for narcotics during the month of March. Fifty-one were for heroin, more than 1 ounce of heroin being incorporated in the aggregate number, or, to be exact, for these prescriptions were all written in the metric system, 35.351 gm. These prescriptions were all for addicts alleged to be under treatment for the cure of the addiction by reduction, so the *letter* of the law is obeyed. Of course, few drug stores handle so much heroin in a month. Naturally, we shall investigate every addict appearing on this report, which is difficult to do, for as soon as an addict begins to feel the reduction he usually goes to another physician and begins at the top again.

Proprietaries not federally exempt are largely prescribed by physicians, as our records show. Chief among them is glyco-heroin; papine is prescribed with relative infrequency. Although not under the narcotic laws, hydrated chloral is justly considered dangerous by the druggists, and many of them are reporting prescriptions for this agent, nearly all of those reported being for bromidia. I have personally examined nine addicts to the latter product. Addicts take paregoric and proprietary preparations containing narcotics in excessive amounts, 1 pint of paregoric at a dose being the extreme we have noted. The extreme dose of morphin, reported by a reliable druggist of Lebanon, was 6 drams at one dose, taken by a woman living in that city. She died some time later, and the details cannot be ascertained.

PRESCRIPTIONS

It is a relatively frequent occurrence for the reports we receive from druggists to carry prescriptions for as much as 1 ounce of morphin. There were three such prescriptions in the January, 1919, report from a drug store in a small town in Northumberland County, as well as five for 1 dram each. In many small towns, similar prescriptions are written, one from a small place in McKean County, carrying 1-dram prescriptions written by a single physician during the month of March in the aggregate of 14⅝ ounces of morphin sulphate. The last is our "prize" record, but we get numerous others which are not far behind it. One drug store in Dauphin County, during the month of February, filled three prescriptions, each for 1 ounce of morphin, and a few months ago filled one for a pound of gum opium. It is common to find a score of prescriptions calling for 1 dram of morphin listed from the stores of one town in a single month.

Records of the foregoing instances, and many more, are on file here, but are open to inspection only by officers of the law, federal or state. Any of the officers named are welcome to come and see, provided they will *do* something in the matter. So far as we can ascertain, the Harrison law has not deterred any of the prescribers noted.

We take up each prescription for an excessive amount of drug with the physician writing it. Of course, most of these are for addicts; but a surprisingly large proportion of them are for aged persons who are a burden to themselves and to every one else. What can the physician do with these people? Many of them have been addicts for forty years, and the physician inherits them from a predecessor who started them on the drug. But many are pure addicts, a few are even of the criminal class. Very many are prostitutes. The medical profession faces a problem—one which we are studying and trying to handle constructively.

Our follow-up on these heaviest prescriptions reveals the fact that some are written for people living at a distance in the country, to save them the inconvenience of a trip to town; it also reveals another fact, which is that there are often in the same family two or three addicts, only one of whom is known to the physician writing the prescription. Occasionally the addict divides with a friend who is a secret user. Occasionally a heavy prescription by a physician turns out to have been for animals on the farm.

We do not conceive it to be the function of the department of health to arrest physicians for technical violations. Our interest lies in the line of prevention and public health, with fair and humane treatment of addicts who are victims of circumstances. We carefully collect evidence, evaluating it judicially and from the clinical standpoint. We issue many warnings to physicians, but report to the authorities the derelict and incorrigible ones, as well as addict physicians and dentists who refuse treatment for their own cure.

Our experience is that the druggists realize the dangers of addiction better than do the physicians. Certainly it is the druggists, and not the physicians, who are the better cooperating with us. We are under many obligations to the pharmacists of the state, practically all of whom are registered with this bureau, while only about one half of the physicians have registered, despite the requirements of the law to this effect. Physicians voluntarily report addicts to us rarely, while the druggists do so very generally.

The heavy prescriber of narcotics always justifies himself in his own eyes, while the druggist compares one physician with another, to the discredit of the heavy prescriber and dispenser. Comparatively few dispensing physicians are heavy buyers of narcotics, but there are enough of them to cause much trouble. The heaviest narcotic purchaser of record with us was a physician, now dead, who bought 400,000 one-quarter-grain morphin pills in one year. He has left a fearful proposition to his successors. Purchases of from 5,000 to 10,000 morphin pills in one year are made by a considerable number of physicians, especially in the north-central district of the state. We fear that some of these physicians come to look on narcotic tablets as so much merchandise, little realizing the harm they are doing with them, for some become very indignant when we write to them about it, and explain, in some instances, that the internal revenue officials raise no issue with them as to their purchases. Of the truth of the latter allegation we have no proof, but as there are about 25,000 dealers, etc., to inspect in the state, and one inspector can adequately examine only six to eight of these in one day, a dozen inspectors, constantly working, are required to cover the state once a year. Naturally, then, a great deal "gets by" without issues being raised.

Hypodermic tablets of morphin figure very prominently in our records of purchases by physicians, and a great many prescriptions are written for them, ranging from twenty-five to 200 tablets each. Some physicians furnish addicts with hypodermic syringes, more especially when the addict's home is remote from the physician's office.

Despite the warnings in the journals and the action of the government, heroin seems to be almost universally used by physicians as a cough sedative. It is displacing codein, largely owing to the fact that, per dose, it costs less than codein. In our view, the manufacture of heroin should be absolutely suppressed.

CLASSIFICATION OF ADDICTS

For purposes of classification we list pure addiction, addiction with disease, addiction with incurable disease, addiction in the aged, and addiction of the criminal.

On the face of the reports, pure addiction is rare; for nearly all addicts claim to have some disease, and any of these persons can find some renegade physician to testify in writing that the individual has disease. Investigation shows the fallacy of most of these reports. We believe that pure addiction really constitutes the larger proportion of all addiction.

Addiction with disease is commonly the result of poor medical or surgical treatment, or of none at all except by medication, which is usually empiric. In relative frequency the diseases named in reports are: neuralgia, chronic diarrhea, asthma, cystitis, other genito-urinary diseases, chronic bronchitis, tertiary syphilis, tuberculosis, various surgical troubles, postoperative troubles, cardiac affections, diabetes and cancer.

Be it noted that conditions actually justifying the continued use of narcotics are relatively infrequent in the reports. The report is commonly "incurable," which means nothing to us here, for we find that while some of these persons have cancer, various other inoperable conditions, etc., most of these reports mean incurable addict; that is to say, the physician does not care to bother with the treatment of addiction, and roughly classes addicts as "incurable."

Except in obviously incurable conditions and addiction, physicians do not like to write "incurable" on a prescription or report, for the very valid reason that it discourages the patient and his friends, and often drives the patient to the quack or the cultist.

VIOLATORS OF THE LAWS

We believe that the greater proportion of the worst medical violators of the narcotic laws are men past 50 years of age. Before restrictive laws were enacted, narcotics could be freely bought and freely prescribed, and many of the elder physicians became accustomed to carrying addicts along, and want to do so now. Empiricism largely accounts for the aged addict and the aged medical offender against the narcotic laws. It is a real charity, in the larger sense, to give aged and diseased addicts adequate modern treatment, for many can be cured of both the disease and the addiction in the hands of capable physicians. To take a charitable view, misplaced sympathy accounts for some physicians catering to drug addicts.

Catering to addiction has become commercially profitable, and it is carried on by two classes, physicians and pedlers, the latter being a small factor as compared with the nefarious activities of a certain class of debased physicians who are commonly in league with equally debased pharmacists and with the underworld. The pedlers we have had arrested are a sordid lot, not half as shrewd as the newspapers credit them with being. We are accumulating evidence against the debased physicians, pedlers, underworld folk, and criminal addicts, and are beginning to employ the Pennsylvania state police in this work. They are one of the finest police organizations in the country, and we expect good results from their activities. They commonly "get" the man they are after.

A striking fact revealed by our records is that veterinarians are very small purchasers of narcotics, despite the fact that the doses they must use are relatively large. Horses and cattle never have drug habits, and they get the drug only when indicated. We wish the same could be said of human beings.

TREATMENT

Some day, we hope, the treatment of drug addiction will be placed on a rational basis. Thus far it has not been. True, there are some institutions and a few men having excellent results. The best results we have seen were in prisons, and for obvious reasons. Perhaps some of the prison methods might be modified and applied elsewhere.

The gradual reduction method, except in the case of addicts with disease, and of aged addicts, appears to us to be a failure. The matter is one, primarily, of detoxication, and vigorous methods are necessary in most cases. Unfortunately, the average physician is opposed to any method of treatment which entails suffering or discomfort on the part of the patient, and hence his treatment is a mere bluff. Yet he expects the patient with peritonitis, typhoid fever, or pneumonia to suffer discomfort during treatment. Until the profession at large changes its attitude toward the treatment of the drug addict, it will accomplish little of definite value. We need a scientific study of the problem in the general hospitals, and they are in better position to treat the addict successfully than are most of the advertised institutions which make a specialty of such cases. What is their duty in the premises? We do not feel like dictating in such a matter, for the principal function of the health officials is prevention, not treatment. We do not recommend any special form of treatment, but the state has provided for the erection of a special hospital for the treatment of alcohol and drug inebriates, which, when completed and in operation, we hope will develop worth-while methods.

Our Pennsylvania experiment has thus far justified itself, but we are not dealing in illusions. It is on a good legal basis, which we hope to strengthen, and we are fully impressed with the immensity of our task. We believe the department of health is in good position to conduct such work. As yet there is little of scientific value to guide us, and the medical profession is not awake to the perils to society and to public health of the various drug addictions, or to what they threaten to become after national prohibition is in force.

Statements regarding bad medical reports, as made in this article, are recorded with infinite regret. But we must face the issues as they actually are. We are going strictly by the law and the evidence, and have no preconceptions. On the other hand, there is ground for great medical encouragement, for fully three fourths of the records coming into this office are so good that they are merely checked off and filed. So, then, we conclude, justly we believe and hope, that ultimately the whole Pennsylvania profession will be found working side by side with us in this reform. We crave medical interest and noncommercial suggestion, and will welcome them.

RECOMMENDATIONS

One engaged in such work as we are undertaking here is apt to become radical. Be this as it may, kindly permit an expression of personal view, for what it may be worth.

After sufficient administrative machinery, both federal and state, is developed, I believe that the importation and sale of *all* habit-inducing drugs should be made a government monopoly; that it should be unlawful for any physician to prescribe or dispense any of these drugs in any but the accepted therapeutic dosage under any conditions, or to buy or possess them in quantity greater than the legitimate therapeutic needs of his own or institutional practice fully justifies; that pharmacists be prohibited from selling them in any quantity whatsoever, and be allowed to fill no prescription calling for more than the usual therapeutic dosage; and that no ready-made or proprietary product carrying any narcotic whatever be allowed to be sold.

I would have an official, not in medical, pharmaceutical or dental practice, in every district, to whom every particle of the government supply for the district should be sent. It would be his duty to estimate the legitimate needs of all professional people and to supply them so much and no more, except in time of public emergency or unusual circumstances. To him should be reported every addict in the district, even inoperable surgical cases, as well as all persons requiring, on the testimony of a physician, doses in excess of the usual; and this official would supply to these persons such amounts as would appear necessary, humanely caring for the addicts already made, but sternly refusing to supply new ones except those with disease which positively demand large doses.

This plan would yield definite results and would relieve the physician of an unwelcome class of work that, in the nature of the case, he cannot handle well. Perhaps there would be much medical objection at first; but I believe it would work so well that the profession at large would soon come to support it most enthusiastically. Certainly it would relieve the profession of a great amount of narcotic bookkeeping and reports, and I believe it would control the problem much better than does any existing plan.

PROTRUSION OF ARTIFICIAL PNEUMOTHORAX INTO THE OPPOSITE UNTREATED SIDE *

BARNETT P. STIVELMAN, M.D.
AND
JOSEPH ROSENBLATT, M.D.
BEDFORD HILLS, N. Y.

The effect of unilateral increase in intrapleural tension, as seen in pleural effusion and spontaneous pneumothorax, on the position of the mediastinal organs, had been well known long before artificial pneumothorax was added to the armamentarium of phthisiotherapy. Indeed, one of the most important signs of pleural effusion and spontaneous pneumothorax is displacement of the heart toward the sound side. Grocco's triangle as a sign of pleural exudate is also supposed to depend on the shifting of the mediastinal contents toward the unaffected side.

Most of the information regarding the effect of increased intrapleural tension on the mediastinum gathered in previous years was, however, mainly the result of observations in cases of pleural effusion. Nitch,[1] in a rather instructive article based on experimental evidence, describes most lucidly the anatomy of the mediastinum, laying particular stress on those vulnerable points which are most likely to yield to increased intrapleural pressure. He, however, seems to put pneumothorax and pleural effusion in one and the same category. It must be pointed out that the hydrostatic pressure of pleural effusion and the pneumatic pressure of pneumothorax will not at all behave in the same manner, the essential difference being that fluid exerts its pressure on most dependent parts, while air exerts pressure equally in all directions. Hence, while fluid will cause displacement mostly of the heart and the lower mediastinal organs, air will produce displacement of these organs as well as distention of the pleural sac at the most vulnerable points, whether this vulnerable point be at the upper or the lower portion of the mediastinum.

It has already been pointed out by various observers that the displacement of the mediastinum during the course of artificial pneumothorax is a rather frequent occurrence. The degree of displacement will depend on the presence or absence of pleural and pleuropericardial adhesions, on the extent of the mobility of the mediastinum in the individual patient, and on the amount of pressure created.

Along with marked displacement of the mediastinum during the course of artificial pneumothorax, we have had occasion to observe another phenonenon, of which, so far as we could find, no mention has been made before. This phenomenon, though associated with displacement of the mediastinum, is dependent on an entirely different factor, and that is extreme distensibility of the pleura.

As has been proved by physical signs and confirmed by roentgenologic examination, the cases that came under our observation showed a pocket of pneumothorax extending into the untreated side to about 3 inches beyond the median line on a level with the first space to the third rib anteriorly. Considering that at this area the two pleural sacs meet at the median line; and furthermore, since, as pointed out by Nitch,[1] the mediastinal space at this area contains nothing but loose areolar tissue, it is surprising, indeed, that we do not observe the pneumothorax extending beyond the median line more often. It is possible, however, that many such cases passed unnoticed.

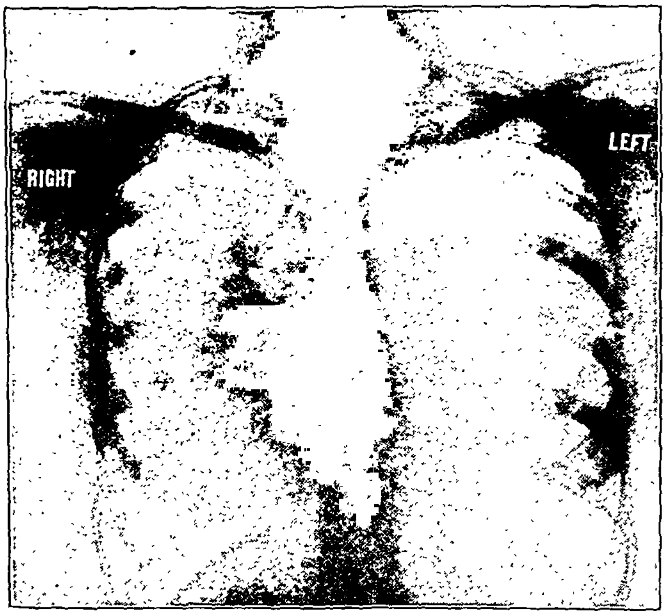

Fig. 1 (Case 1).—Left pneumothorax: mediastinum markedly displaced to right; semicircular area of pneumothorax to right of sternum.

REPORT OF CASES

Case 1.—*History*.—E. H., schoolgirl, aged 17, admitted to Bedford Sanatorium, June 18, 1918, with negative family history and previous personal history, though subject to occasional cough for an indefinite time, had not had symptoms in any way disturbing until about one and a half years before admission, when cough and expectoration greatly increased. At this time, she also experienced elevation of temperature in the late afternoon hours, the fever occasionally rising to 104 F. This condition continued for about three months. During that time she also suffered from frequent night sweats and considerable loss of weight and strength. Accordingly, the patient was admitted to an institution for the tuberculous in New York City, where a physical examination disclosed marked infiltration and cavity formation in the upper half of the left lung, infiltration at the right apex, displacement of the heart considerably to the left, and considerable retraction of the diaphragm on the left side. In view of these physical findings and the rapid progress of the disease, pneumothorax was induced on the left side, Oct. 16, 1917. Subsequent refills were given at regular intervals till March 11, 1918. At no time were there more than 600 c.c. of gas given. The final intrapleural pressure was usually about plus 2 to plus 3 cm. of water. Roentgenograms taken on various occasions disclosed progressive increase in the pneumothorax area and gradual displacement of the mediastinal organs to the right. The improvement in the patient's condition was remarkable. The fever abated, cough and expectoration diminished, and a considerable increase in weight was noted. The patient was transferred to the Bedford Sanatorium, June 18, 1918.

---

* From the Montefiore Home Country Sanatorium.

[1] Nitch, A.: Beitr. z. Klin. d. Tuberc. 18: 1, 1911.

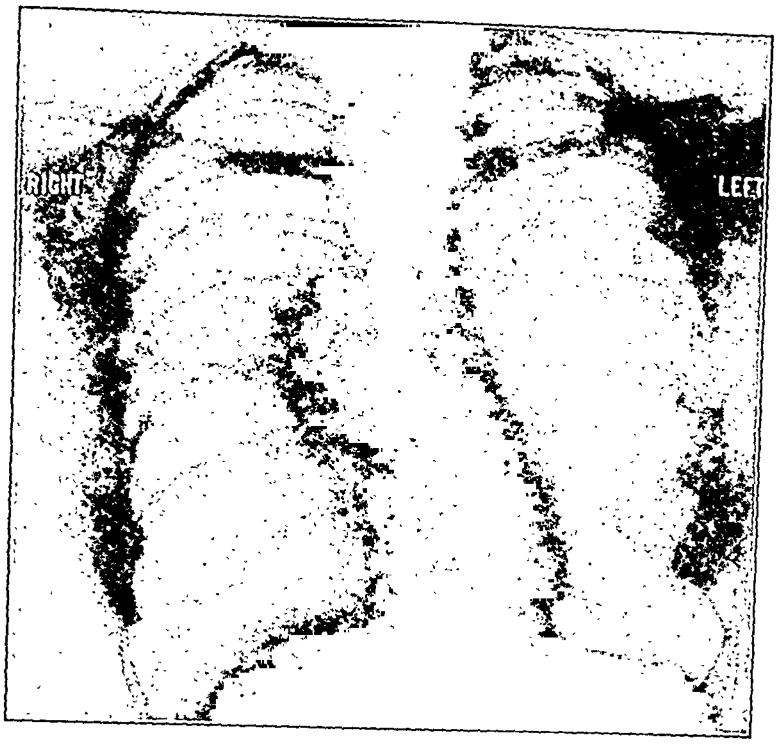

Fig. 2 (Case 1).—Condition five months later: absence of semicircular area of pneumothorax to right of sternum.

Physical Examination.—The left chest was hyperresonant throughout except at the extreme apex. The right chest showed impaired resonance from the apex to the second rib aneriorly. On auscultation, distant amphoric breathing and amphoric whisper were elicited all over the left chest. Breathing and whisper of the same character were heard also over the upper part of the sternum and in the first, second and third spaces to the midclavicular line on the right side. The coin sound during percussion over the left side posteriorly was heard all over the left side anteriorly, extending over the upper part of the sternum and to about the midclavicular line on the right side. There was an area of loud amphoric breathing and whispered pectoriloquy just above and outside of the right nipple.

Fluoroscopy and a roentgenogram (Fig. 1) taken June 10, 1918, disclosed pneumothorax occupying the entire left pleural cavity with the exception of the apex, marked displacement of the mediastinal organs to the right, and a definite semicircular air-containing area extending to about 2 inches to the right of the sternum on a level with the first to the third rib.

Treatment and Course.—Refills were continued at intervals of from three to four weeks, the final pressure at most refills not being more than plus 1 cm. of water. The degree of mediastinal displacement was gradually lessened, and the air-containing semicircular area to the right of the sternum gradually disappeared, as shown in Figure 2.

Case 2.—*History.*—C. P., schoolgirl, aged 16, admitted to Bedford Sanatorium, July 18, 1918, with unimportant family and previous personal history, reported that one and a half years before admission she had caught cold, and had begun to cough and have pain in the chest on breathing. Afternoon rise of temperature and night sweats soon made their appearance, with the inevitable loss of weight and strength. She was confined to her bed for about three months, when she finally gained admission to the Mount Sinai Hospital, New York, where, on account of continued symptoms, marked involvement of the left upper lobe, and a relatively clear right lung, a left pneumothorax was induced, Feb. 1, 1918. Subsequent refills were given at the usual intervals until June 11, and although at no time were there more than 700 c.c. of gas introduced, the final intrapleural pressure was permitted to rise to plus 3 and even to plus 5 on several occasions. The patient improved markedly, most of the symptoms disappearing, and was transferred to Bedford Sanatorium, July 18, for further treatment.

Physical Examination.—On the day after admission there was hyperresonance throughout the left chest and the inner part of the right infraclavicular region. Distant amphoric breathing and amphoric whisper were elicited all over the left chest anteriorly and posteriorly. Breathing and whisper of the same character, pitch and intensity as over the left side were also heard over the upper part of the sternum and to about the midclavicular line in the first, second and third spaces on the right side. During percussion with a coin over the left side posteriorly, a metallic sound could be heard over the upper part of the sternum and over the same area on the right side above described, as well as all over the left side anteriorly. No coin sound could be elicited on percussing the right side posteriorly. The heart was markedly displaced to the right. There was evidence of a small amount of fluid at the left base.

Fluoroscopy and a roentgenogram (Fig. 3) revealed pneumothorax occupying the entire left pleural cavity. An irregular air-containing area, extending to about 2 inches to the right of the right sternal margin encroaching on the right lung and partially collapsing it, was definitely seen.

Treatment and Course.—While the patient remained at the sanatorium, refilling was done at intervals of about three weeks. The amount of air introduced was usually about 400 c.c. and the final intrapleural pressure was never above plus 2 cm. of water.

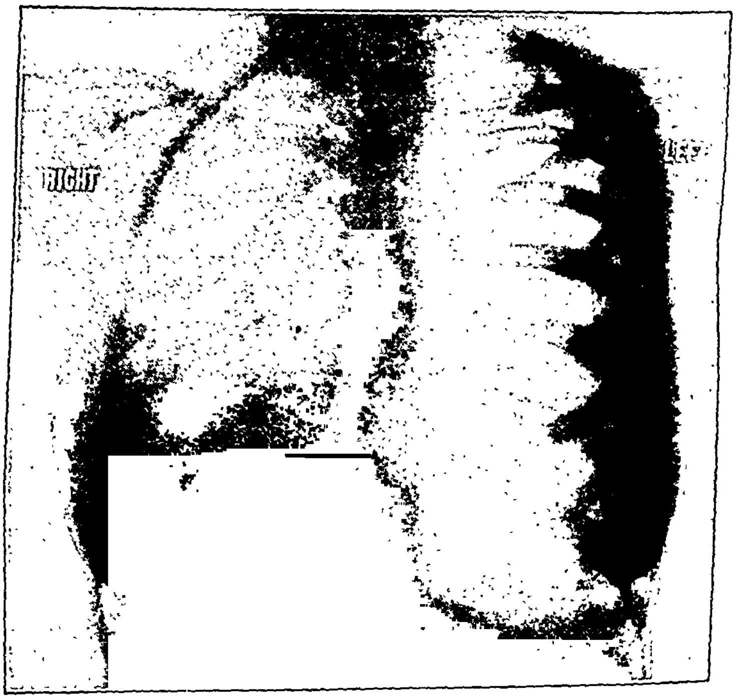

Fig. 3 (Case 2).—Left pneumothorax: mediastinum markedly displaced to right; air-containing space to right of sternum.

During the course of treatment a moderate amount of fluid formed at the left base. The fluid was promptly absorbed, leaving behind rather extensive adhesions at the left base, and as a result of these adhesions the mediastinum was drawn considerably to the left.

Frequent fluoroscopy and roentgenographic examinations showed that the degree of displacement of the mediastinum gradually diminished, the air-containing area that extended to the right of the sternum gradually disappeared, and finally the mediastinum was drawn markedly to the left, as seen in Figures 4 and 5.

COMMENT

These cases deserve scrutiny, since both of them show a characteristic protrusion of the distended pleural sac, encroaching on the untreated side, in addition to marked displacement of the mediastinal organs.

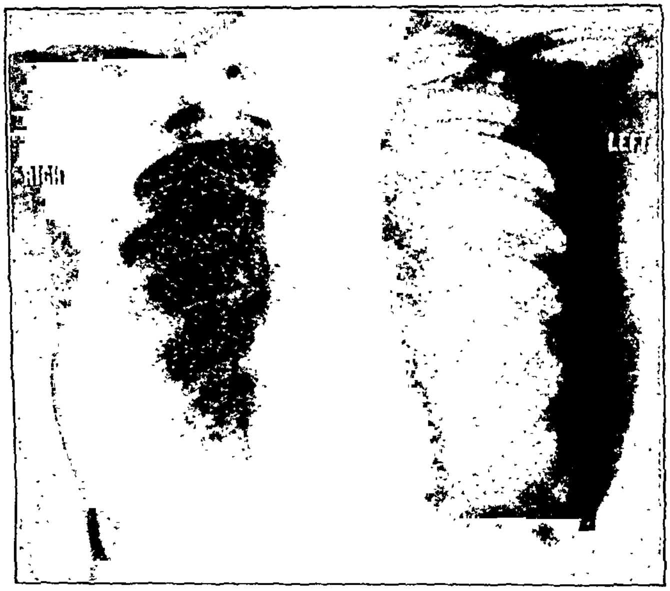

Fig. 4 (Case 2).—Condition six weeks later: air-containing area to right of sternum considerably smaller.

On superficial examination, the amphoric breathing and amphoric whisper that were elicited on the right (untreated) side could be considered as evidence of cavitation on that side. But, as stated above, the amphoric breathing and amphoric whisper that were heard over the upper part of the sternum and over the first, second and third spaces on the right side were exactly of the same quality, pitch and duration as those heard over the left (pneumothorax) side. The same was also true of the coin sound. On percussion over the left side posteriorly, a definite metallic sound was elicited over the above described area on the right side as well as all over the left side anteriorly. These physical signs leave hardly any doubt that the signs on the right (untreated) side were due to the pneumothorax on the left side.

But whether these signs were due to a pocket of pneumothorax actually protruding into the right side, or the pneumothorax signs were merely transmitted from the left to the right side, had as yet to be determined. But this was definitely decided by fluoroscopy and roentgenographic examination.

Figure 1 (Case 1) shows a definite semicircular, air-containing area to the right of the sternum which can hardly be considered as anything else but a protrusion of a left pneumothorax into the right side. Furthermore, Figure 2 of the same patient, taken a few months later, when the intrapleural pressure was reduced, shows that this area has absolutely disappeared, at the same time that the mediastinal organs have returned nearer to their normal position.

Figure 3. Case 2, is perhaps less typical of a protruding pleural sac, as most probably the air-containing area merges into the light area produced by the displaced trachea; but, correlating the physical signs and the roentgenographic findings in both these cases, it could hardly be doubted that in both of them we are dealing with a gas-containing pleural sac protruding from the left to the right side.

The causation of such protrusion can easily be explained, when we remember that opposite the second and third ribs anteriorly the two pleurae meet at the median line. Furthermore, as mentioned above, Nitch has found that at this area the mediastinum contains nothing but loose areolar tissue, owing to the fact that the thymus gland is atrophied in the adult. It is clearly seen that when the pleura is distensible and a certain amount of pressure is introduced, the pleura will easily protrude in this area, which is undeniably its most vulnerable point.

Displacement of the mediastinum was rather marked in both cases. Case 2 shows, in addition, extreme mobility of the mediastinum, since at first a marked displacement to the right is noted, as shown in Figure 3. Figure 4 shows the mediastinum almost in its normal position, and finally marked displacement to the left is to be seen, as an examination of Figure 5 will show.

The degree of mediastinal displacement is dependent on a variety of factors. While a considerable amount of pressure is necessary to produce marked displacement, there are various modifying influences which will either prevent or facilitate displacement of the mediastinal organs. The most important factors that will facilitate mediastinal displacement are absence of pleural and pleuropericardial adhesions, and elasticity and distensibility of the ligaments that hold the mediastinum in place.

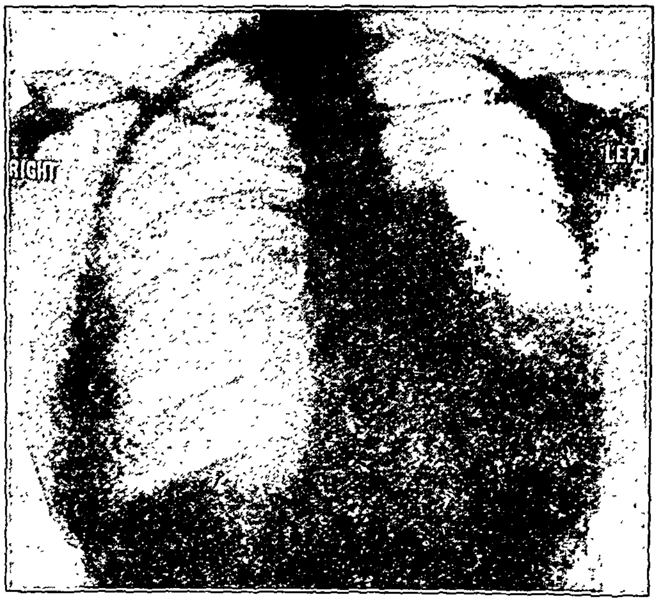

Fig. 5 (Case 2).—Two and a half months after Figure 4: marked displacement of mediastinum to left, and absence of pneumothorax area to right of sternum.

It is to be noted that both our patients are young adults (16 and 17 years of age), and undoubtedly their youth had something to do with the ease with which their mediastinal organs were displaced and their pleurae distended. It is reasonable to suppose that in the young the ligaments are more elastic and the pleura more distensible than in older persons.

EPIDEMIC ENCEPHALITIS LETHARGICA

OR EPIDEMIC SOMNOLENCE, OR EPIDEMIC CEREBRITIS, WITH REPORT OF CASES AND TWO NECROPSIES

BEVERLEY R. TUCKER, M.D.
Professor of Neurology and Psychiatry, Medical College of Virginia
RICHMOND, VA.

In taking up the subject of epidemic encephalitis lethargica I have not gone into the history of the condition because in doing so I would be repeating matter which has already appeared in The Journal.[1] These articles, however, do not refer to certain previous publications on the subject. Dr. I. P. Battle of Rocky Mount, N. C., has kindly furnished me with reference to an article published by Landon Carter Gray, W. B. Pritchard and R. C. Shulz.[2] In this article is described a condition known as "nona" which seems to closely resemble the present epidemic. There also appeared an article by Trautjen[3] in 1890 in which he attributed the condition to the influence of the recent epidemic of influenza. Another article on the condition appeared in 1890 by Hammerslough,[4] and another the same year by Mauthner.[5] This article attributed the pathologic lesions to polioencephalitis superior.

REPORT OF CASES

Case 1.—L., a colored man, aged 21, had no history of influenza or other infectious disease except a probable chancre one year before. There was no history of secondary syphilis, no glandular enlargement, nor apparent signs of syphilis. Somnolence appeared in the latter part of December, 1918, and followed a pain in the chest, a sense of sudden hunger, and great muscular weakness, especially of the legs. He also had headache, vertigo and tinnitus. There was slight elevation of temperature at times. The respiration and pulse were normal. The deep reflexes were exaggerated, there was double ankle clonus, no Kernig's sign and no Babinski reflex. General spasticity was present to a moderate degree. Examination of the eyes revealed photophobia, nystagmus, diplopia, and limitation of lateral excursions. Mentally, the patient was normal when aroused. The cerebrospinal fluid was under greatly increased pressure, globulin test negative, Wassermann test negative. Examination of the blood gave a leukocyte count of 8,200. A Wassermann test on the blood was negative. Examination of the urine was negative. The patient lay in one position unless aroused, but when aroused talked rationally and took medicine and food. There was no incontinence. He was somnolent about a week, and died shortly afterward. Necropsy revealed very severe congestion of the superior longitudinal sinus; cobweb adhesions over the base of the brain involving the cranial nerves and extending down into the cord; marked congestion of the entire cortex; tremendous distension of the third, fourth and lateral ventricles, and swelling and congestion of the pituitary.

Case 2.—P., a white man, aged 30, with no history of influenza, began to be somnolent about one week before coming to the sanatorium. He had a slight elevation of temperature, headache, nausea and vertigo. Preceding the onset he had several days of restlessness and excitement. There was no respiratory involvement. The right knee jerk was absent and the left diminished. There was no Babinski reflex, no clonus and no Kernig's sign. There was no muscular rigidity. He had double ptosis, conjunctivitis and diplopia and the pupils were sluggish to light. The patient had slight exophthalmos, choked disk on the right, and slight blurring of the left eye ground. The blood pressure was normal. A lumbar puncture revealed the fluid under increased pressure; the cell count was 35, and the globulin slightly increased. Wassermann tests on both the cerebrospinal fluid and the blood were negative. There was a leukocytosis of 17,600. The urea content of the blood was increased. The urine showed a specific gravity of 1.014, some hyaline and granular casts, and no albumin, but there were no clinical signs of a uremic condition. The patient slept most of the time and lay in one position, speaking only when spoken to, and then only in monosyllables. He could be aroused for food and medicine and urination and defecation, but immediately became somnolent again. He died after sixteen days of somnolence. His respiration kept up ten minutes after his heart stopped. Necropsy was refused.

Case 3.—C., a white boy, aged 7 years, had influenza in October, 1918, recovered, and remained well until Feb. 22, 1919, when he began to be somnolent, and had a temperature between 100 and 102 F. for four or five days. Since then his pulse and respiration have been normal and there has been no respiratory involvement. He has had no nausea or headache but occasional vomiting. The patient had no clonus, no Kernig's sign and no Babinski reflex. His knee jerks were normal. There was no cranial nerve involvement. The muscular tone was catatonic, and "lead pipe" rigidity was present. The pupils were slightly dilated and sluggish to light, but the fundi were negative. When aroused he would look at one, but he spoke only a few words the four weeks he was somnolent. The cerebrospinal fluid showed moderately increased fluid pressure; cell count, globulin and the Wassermann test were negative. There was a leukocytosis of 12,400; polymorphonuclears, 43 per cent.; small lymphocytes, 50 per cent.; large lymphocytes, 6 per cent.; eosinophils, 1 per cent.; malaria, negative. The blood urea was increased. The urine was negative. The child did not change his position in bed; he could be aroused for food and medicine, but refused to talk. He had incontinence of urine and feces unless aroused. He recovered after four weeks of somnolence.

Case 4.—T., a white man, aged 41, had influenza in November, 1918, and was sick ten days with fever, cough, headache and delirium. This was followed in a few days by a right hemiplegia with aphasia, thought to be due to a cerebral thrombus. The somnolence began about two weeks after the influenza, and has kept up ever since. The patients temperature was between 100 and 102 F. for two months, but it has since been normal. His respiration has been normal and his pulse has ranged between 66 and 90. He has had no respiratory involvement since influenza in November. He has had occasional headache and vomiting, but no vertigo. At first he had a slight Kernig's sign, Babinski reflex on the right, right hemiplegia, left facial palsy, slight clonus on the right, and general spasticity. The Babinski reflex and clonus have disappeared, and the spasticity has improved. The pupils were sluggish, and at first there was moderate choking of both disks. The patient rarely speaks or attempts to speak, and is very lethargic. The cerebrospinal fluid was under pressure, the cells and globulin were increased, the Wassermann test and culture on the fluid were negative. The leukocyte count was 10,000 and the blood Wassermann test negative. A blood culture disclosed the presence of *Bacillus pyocyaneus*, but this disappeared under autogenous vaccine. The urine has been negative throughout. The blood pressure has ranged around 130 systolic and 90 diastolic. The patient can be aroused for food and medicine and looks around, but otherwise has been profoundly somnolent for over three months, and has incontinence of urine and feces.

Case 5.—S., a white man, aged 28, with no history of influenza, began to be somnolent, Feb. 25, 1919, and developed a rise of temperature ranging from 99 to 100 F. The pulse and respiration were normal and he had no symptoms of respiratory tract involvement. At first he had headache, but no vomiting nor vertigo. He had no Babinski reflex, no Kernig's sign, no clonus and no rigidity. The knee jerks were absent. When aroused, he complained of diplopia; the pupils were dilated and did not react to light. He had bilateral choked disk and bilateral ptosis. The conjunctivae were somewhat injected. The spinal fluid was under greatly increased pressure, the color clear, and the cell and globulin content increased. The Wassermann test was negative. There was a leukocytosis of 14,000. The blood showed a moderate increase in the urea content. The urine was negative and the blood pressure normal. The patient was profoundly somnolent but could be aroused for food and medicine. When aroused, he would answer questions only in monosyllables and would not speak voluntarily. He lay in one position unless moved, and had incontinence of urine and feces. He died after twenty days of somnolence. A necropsy of the brain was performed by Dr. S. W. Budd of Richmond.

[5] Mauthner, Ludwig: Wien. med. Wchnschr., July, 1890.

The skull was opened in the usual manner. After removal of the skull-cap it was noticed that there was considerable congestion of the dura and underlying tissues, and that along the longitudinal sinus there were many varicosities on each side in the region of the fissure of Rolando. On removal of the dura it was noted that all of the membranes were attached to the cortex for 1½ or 2 inches on each side of the longitudinal sinus. Elsewhere the brain was in no way adherent to the membranes. On removal of the brain there was noticed a thin, delicate, inflammatory membrane over the base and extending well up over the temporal lobes of the brain. This membrane was prominent around the cranial nerves, the pons and the medulla, and there were a number of cobweb adhesions between the cranial nerves and the brain. On section of the cortex of the brain the capillaries were distended, but there was no evidence of macroscopic hemorrhage. The lateral and third ventricles were not dilated. There was no evidence of congestion or hemorrhage in the region of the fourth ventricle. On section through the cerebellum the tissues looked normal. Microscopic examination of the cortex of the temporal lobes showed a slight enlargement of the capillaries, with occasional polymorphonuclear leukocytes around the capillaries, and the individual nerve cells seemed a little larger than normal. The pia mater and the arachnoid were infiltrated with a moderate amount of fibrin and polymorphonuclear leukocytes, and the capillaries were much distended. The medulla, pons and cerebellum showed the same histologic changes as the cortex. Cultures from the base of the brain and the meninges were negative for pathogenic organisms. The pituitary body was much congested and infiltrated with blood cells into the tissues. There was also some cloudy swelling of the cells of the pituitary body. This congestion was in both the anterior and the posterior lobes of the gland. The pituitary body was also enlarged in size.

CASE 6.—B., a white man, aged 51, was thought to have influenza in August, 1918. He had taken sick, March 1, 1919, with a temperature ranging from 100 to 101 F. for a week, but with no cough or respiratory symptoms. March 14, the patient became somnolent and slept most of the time for a week. Pulse and respiration were normal. There was no respiratory tract involvement, vomiting nor headache, but there was some vertigo. There was a bilateral Babinski reflex, but no clonus. The knee jerks were negative, and the speech was a little thick. The conjunctivae were injected. The patient complained of diplopia, and the pupils were somewhat contracted. The blood pressure was normal. The spinal fluid was under increased pressure, the cell count 25, globulin increased, Wassermann test negative. The leukocyte count was not made. The urine was negative. The patient was very somnolent, did not change his expression or his position in bed, and rarely spoke, but would eat, urinate and defecate when aroused. He remained somnolent for a week.

The symptoms in the remaining five cases practically corresponded to those in the cases more fully reported. Only the striking points of these five are mentioned:

CASE 7.—F., a child, was somnolent for three days, and for several days afterward showed marked difficulty in gait with practically no changes in the deep reflexes. He made an uneventful recovery in a week.

CASE 8.—B. showed the usual symptoms, and was the only patient that showed difficulty in hearing. He had considerable nerve deafness on the right. There was also paresis of both oculomotor, right facial and the right hypoglossal. Somnolence lasted a week, and he made an uneventful recovery.

CASE 9.—M. did not give a history of influenza but had considerable rigidity, and the case somewhat resembled meningitis. The spinal fluid, however, was negative and the somnolence lasted only four days. The patient made an uneventful recovery.

CASE 10.—C. presented a typical case in which somnolence lasted about twelve days. This was the only case in which a roentgenogram of the skull was made. The roentgenographic findings were entirely negative.

CASE 11.—T. resembled the others except that he had very low blood pressure, it being 76 systolic and 58 diastolic on admission. This gradually became normal within three weeks. His somnolence lasted five days, and he made an uneventful recovery.

DEDUCTIONS

The incidence of influenza in these cases, and in others I have seen, is so striking that I believe epidemic encephalitis lethargica is either a manifestation of a recrudescence or recurrence of influenza, or in certain cases the expression of influenza per se. This is not absolutely proved, but is the most probable conjecture.

Since the height of the influenza epidemic there have been observed, all over the country, numerous cases of influenza which had, as sequelae, vertigo, depression of spirits or mania, and one or more cranial nerve affections. These cases are probably cases of encephalitis of more or less severity sine lethargica.

I cannot see any relation between epidemic encephalitis lethargica and infantile paralysis, either clinically or pathologically, nor do I think these cases should be termed meningitis, because the usual organisms of meningitis cannot be found in the cerebrospinal fluid, and pus is not found in the meninges at necropsy. Again, the clinical symptoms are not typically those of meningitis, even in the cases presenting spinal rigidity.

Epidemic encephalitis lethargica appears to resemble brain abscess more than any other condition. In fact, I have had three cases sent to me with the diagnosis of brain abscess. The history of rise of temperature, vomiting, vertigo and headache, and the finding of choked disks, cranial nerve palsies, drowsiness, leukocytosis and increased cerebrospinal fluid pressure in both conditions make a careful differential diagnosis necessary.

Epidemic encephalitis lethargica seems to be due to congestion of the pia and the encephalon, chiefly at the base of the brain, and to be accompanied by a slight inflammatory exudate affecting various cranial nerve roots and causing, as a rule, increased intracranial pressure with increased globulin content and increased cell count in the fluid.

Examination of the urine reveals nothing of special interest, but examination of the blood presents an almost constant moderate leukocytosis, and commonly an increase in the urea content.

We seem to be dealing more with a syndrome than with a new disease, and this syndrome is chiefly manifested by moderate transient elevation of temperature and frequently by headache, vertigo, vomiting, conjunctivitis, diplopia, choked disk, various cranial nerve palsies, muscular rigidities, changes in reflexes, increased cerebrospinal pressure with increased cell count and globulin content, increased blood urea, and last, but not least, somnolence, from which the patients may be aroused for food and medicine, but in which they usually lie without change of position or expression, and have incontinence of urine and feces.

I believe that the somnolence is chiefly due to pressure and inflammation of the pituitary gland.

ANTERIOR DISLOCATION OF THE ATLAS WITH A BREAK IN THE CONTINUITY OF THE ANTERIOR ARCH *

JACOB J. SYBENGA, M.D. (Pella, Iowa)
First Lieutenant, M. C., U. S. Army
COLONIA, N. J.

In view of the fact that the combination of a break in continuity and dislocation of the atlas is rather unusual and that the patient gave a history of symptoms from the date of injury which might be attributed to this condition, this case seems of interest to report.

REPORT OF CASE

A private, aged 24, a ground man in an aero squad, a college student before entering the army, with a negative history, was injured by making his escape from a German air raid on the aerodrome to which he was attached, Aug. 17, 1918. He was found in an unconscious state along the roadside, and was taken to a dressing station, where a few hours later he regained consciousness. The patient remained here for ten days, during which time he suffered from intense headache and pain in the neck. Morphin was administered and also acetylsalicylic acid, but a diagnosis was not made.

He was transferred from this station to Hospital No. 13, at Boulogne. Here a roentgen examination was made and a diagnosis of skull fracture was reported. The symptoms increased in intensity, and the treatment was continued. After several days he was removed to Base Hospital No. 37, Dartford, England. The roentgen examination at this hospital was said to be negative. A diagnosis of eyestrain was made and the patient was fitted with glasses. The severe headache and the pain in the neck continued, in conjunction with which the patient said that his mind would become a blank at times. He lost weight and suffered from insomnia. Morphin and acetylsalicylic acid were administered for pain.

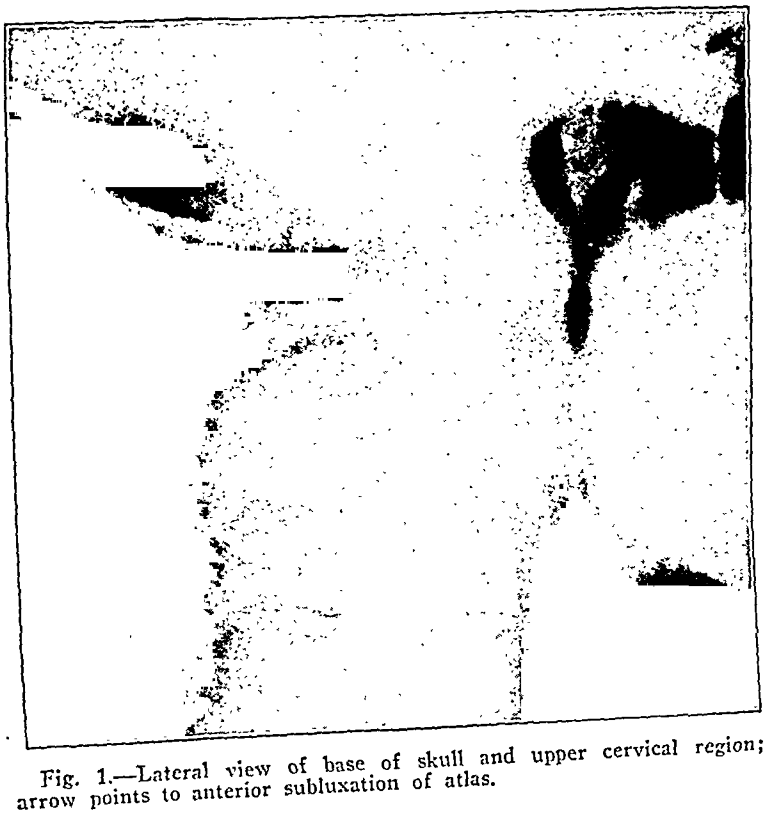

Fig. 1.—Lateral view of base of skull and upper cervical region; arrow points to anterior subluxation of atlas.

After two months he returned to this country, arriving at Staten Island, December 16. One month later he was transferred to U. S. Army General Hospital No. 3, at Colonia, N. J.

On admission the condition of the patient was good, but he complained of severe pain in the head and the neck which was more marked on the right side. The neck was stiff, rotation was limited, and the patient maintained a characteristic position of the head.

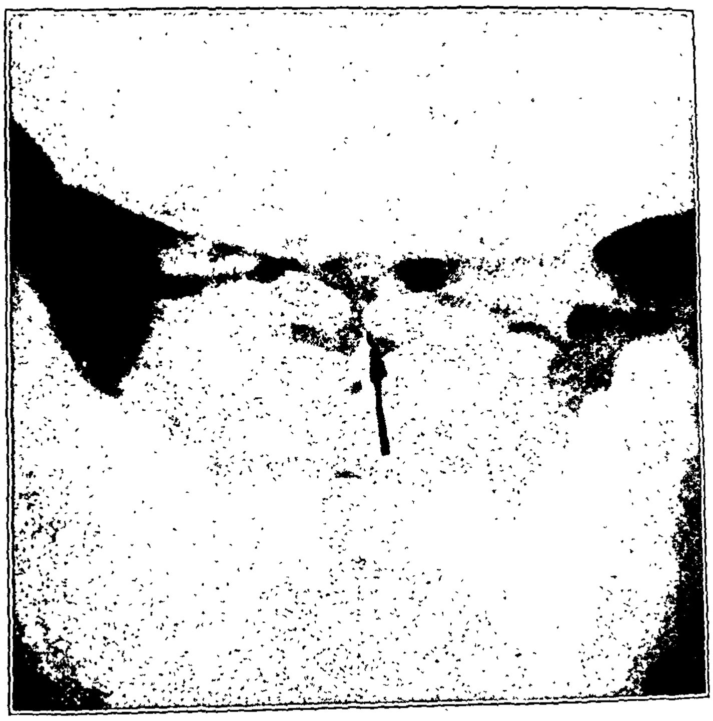

Fig. 2.—Anteroposterior view of atlas and axis through open mouth; arrow indicates break in continuity of anterior arch of atlas.

The department of neurology reported: cranial nerves negative; no palsies nor ataxias; superficial reflex active and equal; deep reflex exaggerated; right knee jerk definitely more active than left. The musculature of the limbs of the right side suggested more tone, and there appeared also to be somewhat stronger power in the left limbs (which, however, might be more apparent than real). There were no sensory changes, but some tenderness was found on percussion just below the inion. Another important and interesting symptom which developed just recently is that while the patient was on his way home on furlough, he temporarily had to abandon his trip and was taken to a hospital because of the severe pain which he developed in the head and the neck as a result of the jolting of the train.

The patient was referred to the department of roentgenology, Jan. 20, 1919, for the purpose of determining a possible skull fracture.

A stereoscopic examination was made of the skull and the upper cervical region. It was found that the skull was free from fracture, but that there was an anterior displacement of the atlas, as shown in Figure 1. An anteroposterior exposure was then made through the open mouth. This examination shows a break in the continuity of the anterior arch of the atlas, as shown in Figure 2.

Although several other plates were made to determine a possible error, each following examination showed an absence of skull fracture, but with these findings always present, namely: There was an anterior displacement of the atlas with a break in continuity of the anterior arch; the odontoid process was intact and free from bony articulation, and the anterior surface of anterior tubercle of the atlas was on a plane anterior to that of the anterior margin of the body of the axis.

The nasopharynx was examined, and a definite bulging mass, which was thought to be the anterior arch of the atlas, was found to occupy part of the cavity.

In view of the fact that the anterior arch sometimes develops from two centers instead of one, we have

---

* From U. S. Army General Hospital No. 3.

thought about the possibility of the break in continuity as being a lack of fusion of the centers, rather than the result of a fracture due to the injury. There is, however, no question in regard to the anterior subluxation of the atlas, both from the roentgen findings and also clinically.

SPONTANEOUS PERIRENAL HEMORRHAGE (HEMATOMA)

KARL A. MEYER, M.D.
Medical Superintendent, Cook County Hospital
CHICAGO

The infrequency of spontaneous rupture of the kidney, only about thirty cases being recorded, and its seriousness without early surgical intervention, lead me to make this report of two cases. The fact that the patients were admitted to medical services and were kept under observation for some time before being transferred for surgical treatment is evidence that the condition is also of importance to internists.

REPORT OF CASES

Case 1.—*History.*—J. S., man, aged 27, admitted, Dec. 26, 1916, to the service of Dr. Roger T. Vaughan, with a diagnosis of lumbago, gave a history of pain over both kidneys for three weeks, increasing each day, and with exacerbations every ten to twenty minutes, so acute as to cause writhing and groaning. There was no vomiting nor nausea, and the pain did not radiate.

For five months, and ending four months previous to admittance, he had been employed in a place where anilin dyes were made. He left this occupation perfectly well, but urination for some time had occurred three or four times each night, and from four to six times daily. The family history was negative. The only prior illness, about four years previously, was diagnosed as a severe stomach trouble and was accompanied by vomiting and pain in the epigastrium and at a corresponding level in the back. This illness lasted three months. Syphilis and gonorrhea were emphatically denied. The patient was accustomed to drink about one-half pint of whisky every day. With the present illness there was no nausea nor vomiting.

Examination.—On admission the patient was very ill; the face was drawn; the eyes were sunken, and he was groaning most of the time and rolling about at times on his hands and knees and again lying flat on the abdomen. The temperature was 100 F.; pulse, 76; respirations, 20. Physical examination of the head, neck and chest was negative. The abdomen was flat, soft and without rigidity. There was tenderness on the left side in the region of the descending colon. There was no palpable mass in the abdomen. The Wassermann test was negative, culture mediums inoculated with the blood remained normal. Blood count revealed: leukocytes, 24,000; polymorphonuclears, 67 per cent.; small mononuclears, 16 per cent.; large mononuclears, 7 per cent. There were many pus cells and a few hyaline casts in the urine. The specific gravity was 1.020. There was no sugar. The roentgenographic examination for renal and bladder calculi was negative.

Jan. 7, 1917, there was pain in the shoulders and arms and lumbar region. There was increase of pain with movement. Blood count disclosed: leukocytes, 30,000. There were pus cells in the urine.

January 20, there was sharp, severe and continuous abdominal pain in the right iliac region and tenderness over McBurney's point. There was rigidity of the right rectus abdominal muscle. Constipation had been in evidence for two days, and was relieved by colonic flushing, but this failed to relieve the pain. There were 78,000 leukocytes. A diagnosis of appendicitis was reached, and the patient was transferred to the surgical service.

Operation.—When the abdomen was opened through a right rectus incision, the only lesion found was a large, dark, retroperitoneal mass which was opened external to the cecum and emptied of about 30 ounces of clotted blood. The clots were laminated and obviously the result of repeated hemorrhages. Exploration of the cavity revealed a perforation of the kidney. The abdominal wound was closed and the kidney was removed by the usual lumbar incision. The clamps left on the kidney pedicle were loosened after three days and were removed on the fourth. Recovery followed without noteworthy developments, and the patient was discharged, March 7, 1917.

Examination of the Kidney.—Gross and microscopic examination of the kidney demonstrated an ascending infection with multiple abscesses, with erosion (necrosis) of an arcuate artery and the formation of a small crater-like tear in the lower pole, 2 cm. deep in the cortex with extension of the hemorrhage from here into the perirenal fat, where there was still considerable blood.

Case 2.—*History.*—M. S., man, negro, aged 42, admitted to the medical service of Dr. Milton Portis, Aug. 8, 1918, complained of pain in the abdomen and back, vomiting and retention of urine. The illness had begun two months previously and one month after pneumonia, with the pain as stated in the back and abdomen, and with sharp attacks when the pain radiated to the genitals, the left thigh and occasionally to the left knee. Tenderness all over the left side was constant. There was a history of polyuria and of two urinations, as a rule, each night. About three weeks before admission the urine was red with blood and contained small clots on two occasions.

Examination.—On entrance a systolic murmur was heard at the apex, and the heart was apparently pushed upward a little. Expansion of the left side of the chest was somewhat limited. Systolic blood pressure was 120 mm.; diastolic, 60 mm. Pulse, respirations and temperature were normal. There was tenderness over the whole left side of the back up to the eighth rib and to the midline behind. The abdomen bulged somewhat on the left side, where a mass was felt extending up to the fourth rib and down to the iliac crest—a firm mass without notches, unmoved by breathing. Tenderness was present on the left side, as was found by rectal examination.

Cystoscopic examination by Dr. Harry Culver revealed the fact that a 24 French urethral sound passed without difficulty. The bladder was tolerant to fluid and to instruments. There was no blood in the urine, but a large, partly organized clot was found on the lining of the base of the bladder. The mucosa of the bladder was otherwise normal. Both ureters were catheterized without difficulty. The urine became clear after irrigation with sterile water. Of the left renal pelvis, the capacity of which was 18 c.c., a pyelogram was made.

Blood test revealed: hemoglobin, 75 per cent.; leukocytes, 25,500; polymorphonuclears, 94 per cent.

The clinical diagnosis was hypernephroma of the left kidney.

Operation.—Following transference to the surgical service, the abdomen was opened, August 15, through a long vertical incision in the left rectus abdominis region. Conditions in the abdomen were found normal, except for an enormous, dark purple mass located retroperitoneally on the left side. An opening was made through the mesocolon and about 3 liters of blood, most of which had been clotted for some time, were removed. The clots in this case were also somewhat laminated. The kidney appeared to be softer than normal, but was normal in size and no tumor was found. On account of the serious condition of the patient, the cavity was packed with gauze and the abdomen closed. Death occurred the next day. It was impossible to obtain a postmortem examination.

COMMENT

In view of the history of pneumonia and a heart murmur, it may well be thought, in this second instance, that the lesion of the kidney was originally a hemorrhagic infarct. According to Lippens,[1] with these spontaneous hemorrhages, dissection of the capsule from the kidney may be either localized or general. An extracapsular hemorrhage may become circumscribed or encysted.

---

[1] Lippens, A.: L'hématome périrénal spontané, J. de chir. **11:** 1, 1913.

Severe pain in the kidney region, the presence of a tumor-like mass of variable dimensions, and evidence of internal bleeding are important symptoms. The pain is quite variable in character, radiating usually downward, but sometimes toward the shoulder. It may simulate closely the pain of renal colic. At times it is acute. Of great importance is the presence of blood in the urine. In some cases, jaundice, but not marked, has been noted. In only one case[2] has the diagnosis been made before operation.

Perirenal hemorrhages, such as these, need prompt operation and the amount of hemorrhage may make the prognosis grave. Whether nephrectomy should be done or not must depend on the conditions.

POSTINFLUENZAL ALOPECIA

H. H. HAZEN, M.D.
Professor of Dermatology, Georgetown University School of Medicine; Professor of Dermatology, Howard University School of Medicine
WASHINGTON, D. C.

Alopecia following any severe febrile affection is a common occurrence. Morrisey[1] states that the older literature gives no references to a postinfluenzal alopecia, but Jackson and McMurtry[2] note that, of ninety-seven private patients suffering from a febrile alopecia, influenza was responsible for nine.

There is still some question as to whether the loss of hair after fevers is due to interference with the nutrition or to a toxin acting directly on the hair papillae, although the former view is more generally held. Most of the writers agree that a preexisting seborrhea makes the loss of hair more certain.

To date I have seen fifty patients suffering from alopecia following influenza. Of these, three were men and forty-seven were women. It is highly probable that women are much more apt to consult a physician, men feeling that the affection is trivial and hardly worth troubling about. Several of the more intelligent barbers have told me that practically all of their customers who had had influenza lost much of their hair. As the epidemic was more severe among the young it is only natural that the alopecia patients were all young. Unquestionably the severity of the disease has much to do with the subsequent loss of hair. One third of my patients had had a severe pneumonia, and only five of the fifty had had fever of less than 102.5 F. On the other hand, I am by no means convinced that a preexisting seborrhea played any great part, for twenty of the fifty stated that they had had practically no dandruff, and the scalps of twenty-two of the fifty were absolutely free from any local trouble, care being taken that in no instance were the scalps washed less than ten days before examination. The average time elapsing from the onset of the influenza to the beginning of the alopecia was nine weeks. The shortest time was two weeks, and the longest three months. The amount of hair lost varied greatly. In one case there remained only one tuft of hair on the back of the scalp, and as another extreme, not more than a tenth of the hair was lost. As nearly as can be estimated, largely from the thickness of braids, the average loss of hair was from one third to one half. As a rule only the long hairs fell, and these were almost immediately replaced by short hairs, so it is probable that new hairs simply push out the old hairs that have been damaged. The greatest loss of hair was usually over the anterior and parietal portions of the scalp. The alopecia was diffuse, not patchy, although in two cases there was a tendency toward patchiness. In one instance there was one completely bald area about 1½ inches in diameter. Only twelve of the patients complained of sensitiveness, either local or general, of the scalp. In forty-one cases both scalp and hair were abnormally dry.

Without exception every patient has developed new hair in a very short space of time; in fact, it would probably be difficult to prevent new hair from coming in.

The treatment is simple: First, the patient must be put in good physical condition and reassured that the prognosis is good. Next, the scalp must be cleansed of any seborrhea. This can usually be done by means of a sulphur ointment. Sufficient vegetable oil must be supplied to the hair to keep it glossy; this is best done by wetting slightly a cloth with the oil, and then rubbing it over separate strands of hair. Sufficient massage should be done twice a day to cause a brisk tingle of the scalp. When the scalp is cleansed of seborrhea, a simple stimulating lotion should be used at night. A dram of salicylic acid to 6 ounces of alcohol or bay rum will work perfectly well. There is not the slightest need for treatment with ultraviolet light or with any form of electrical stimulation. Also there is not the slightest excuse for cutting the hair, unless it be to make the ends even, so that it can be more easily dressed. In all cases a light hat should be worn so as not to interfere with circulation or ventilation.

Postinfluenzal alopecia differs in no wise from any other postfebrile alopecia. In practically all cases the prognosis is excellent. Simple cleansing of the scalp and a stimulating tonic with ordinary hygiene of the scalp is all the treatment required.

1621 Connecticut Avenue.

Central Council for Infant Welfare.—A Central Council for Infant and Child Welfare was inaugurated in London recently. The council consisted of representatives of various infants', children's, mothers' and allied organizations, thirteen in number. The object of the council are to coordinate the work of the various national and local voluntary organizations concerned in the care of motherhood, infancy and childhood by organizing the supply and distribution of funds and workers, both voluntary and salaried; to establish, supervise and maintain, with the help of government grants and payments by beneficiaries, such residential institutions or to make such other arrangements for the benefit of the mothers and young children as the constituent societies may from time to time find necessary; to provide and promote a standardization of training for social welfare workers in connection with motherhood, infancy and childhood, and to raise the status and remuneration of the workers. The chairman of the council is Sir Arthur Stanley, and the secretary is Miss Wilson; the offices for the time being will be at 83, Pall Mall.—*Medical Officer* **21**:122, 1919.

AN INDEX OF BODY RESISTANCE IN ACUTE INFLAMMATORY PROCESSES

AS INDICATED BY EXAMINATION OF THE BLOOD

ORVILLE J. WALKER, M.D. (Oklahoma City)
Lieutenant, M. C., U. S. Army
CAMP SHERMAN, CHILLICOTHE, OHIO

Hematology today is recognized as one of our most valuable aids in the diagnosis and prognosis of acute inflammatory processes. Still, we find many who are at a loss as to the significance and interpretation of blood pictures in any given condition. In many hospitals a total leukocyte count alone is made, even though it is a well recognized fact among hematologists that of the two parts of a blood picture, that is, total leukocyte count and differential count, the latter is by far the more valuable, while the most valuable data are obtained from the comparative relation of the total leukocyte count and the polymorphonuclear percentage.

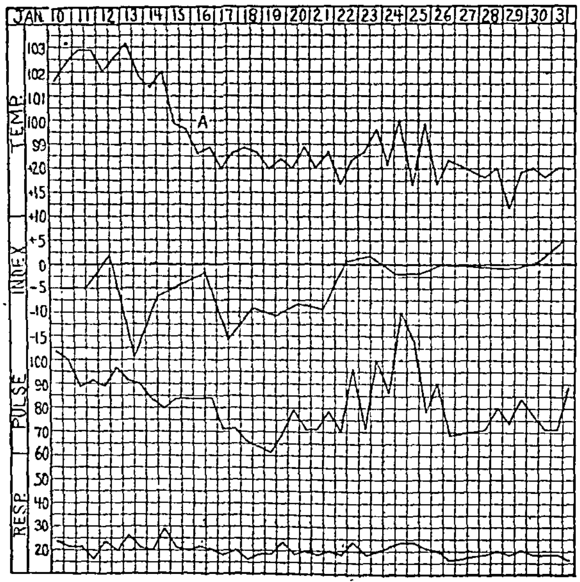

Chart 1 (Case 74).—Temperature, pulse, respiration and index on one chart in a case of influenzal pneumonia: *A*, lysis.

In the early days of blood counting when this branch of hematology was receiving a great deal of attention from investigators, Sondern[1] published a paper which stands out as a high light among the numerous ones appearing on the subject at that time. After careful blood examinations of more than 5,000 cases, including 1,415 surgical cases, he drew hypotheses that have stood the test of time.

His conclusions were in part as follows:

> Leukocytosis is largely dependent on body resistance toward infection, and therefore the degree of increase can be no guide to the intensity of the pathological process. Good resistance will produce pronounced leukocytosis, even in slight infections; and poor resistance, but little leukocytosis in slight infection, and possibly none at all in grave infections. . . .
>
> The quantitative relation or differential count of leukocytes offers a far better guide to the status of an inflammatory process, and is one which is not influenced to a perceptible degree by body resistance. Furthermore, the leukocytosis present with a given differential count is a direct indicator of body resistance, which may also be of great clinical value.

He very aptly divided blood findings into three distinct pictures:

1. A relative percentage of polynuclear cells below 70 with an inflammatory leukocytosis of any degree excludes the presence of gangrene or pus at the time the blood examination is made, and usually indicates good body resistance toward infection. For example: serous otitis media with a total leukocyte count of 28,400 and a percentage of polynuclears of 59.7; and acute appendicitis with a total leukocyte count of 25,100 and a percentage of polynuclears of 63.5.

2. An increased relative percentage of polynuclear cells with little or no inflammatory leukocytosis is still an absolute indication of inflammatory process, and the percentage is a direct guide to the severity of the infection. For example: pelvic abscess with 7,200 total leukocytes and 87 per cent. polynuclears; gangrenous appendicitis and spreading general peritonitis with a total of 13,200 leukocytes and 82.4 per cent. polynuclears, and brain abscess following mastoiditis with a total of 11,900 leukocytes and 82.3 per cent. polynuclears.

3. An increased relative percentage of polynuclear cells with a decided inflammatory leukocytosis (most cases like this).

Gibson,[2] making use of Sondern's hypothesis, after a study of several hundred blood pictures in appendicitis and other acute surgical conditions, evolved a "standard chart" which was cleverly arranged to show graphically the disproportion between total leukocyte and polymorphonuclear percentage in any blood examination. He found that "in acute inflammations which are well resisted, the polynuclears are increased approximately one degree per cent. for every one thousand of the total above 10,000." Using millimeter graph paper and allowing a square millimeter to represent each 1,000 increase of the total above 10,000 and likewise each degree per cent. increase above 75, he was able to follow from time to time the change in the "disproportion" in any condition. His conclusions were as follows:

> The differential blood count and its relation to the total leukocytosis is the most valuable diagnostic and prognostic aid in acute surgical diseases that is furnished by any of the methods of blood examination.
>
> It is of value chiefly in indicating fairly consistently the existence of suppuration or gangrene, as evidenced by an increase of the polynuclear cells disproportionately high as compared to the total leukocytosis. The greater the disproportion the surer the findings, and in extreme disproportion, the method has proved itself practically infallible.
>
> As the relative disproportion between the leukocytosis and the percentage of polynuclear cells is so much more valuable than the findings based on a leukocyte count alone, this latter method should be abandoned in favor of the newer and more reliable procedure.

However, Gibson's chart met with the objection that if many successive counts were entered on the same chart, it was apt to result in a jumble of lines that were difficult to follow. So Wilson[3] modified the "standard chart." After using it at the Mayo Clinic in several hundred cases, his conclusions were as follows:

1. Sondern's hypothesis, that the polynuclear percentage is an index of infection, the total leukocytosis an index of body reaction, and their proportionate relationship an index of resistance, seems to be supported. The more important exceptions to this are in moribund cases and perhaps children.

2. As practically applied in early appendicitis cases, a disproportional polynuclear increase, i. e., a rising resistance line,

[3] Wilson, L. B.: Value of Sondern's Differential Leukocyte Resistance Line in the Diagnosis and Prognosis of Acute Appendicitis, Collected Papers of the Mayo Clinics, 1905-1909, p. 280.

indicates a more or less severe infection, which is not being properly cared for by the body. The higher and longer this line, the more serious the case.

3. A proportional polynuclear percentage or a disproportional polynuclear decrease, if well marked, indicates mild or well-cared-for infection.

4. The value to the surgeon in early cases is but little, since most early cases are operated on anyway. It may be of some value negatively in indicating that a supposedly acute exacerbation of chronic appendicitis is not present.

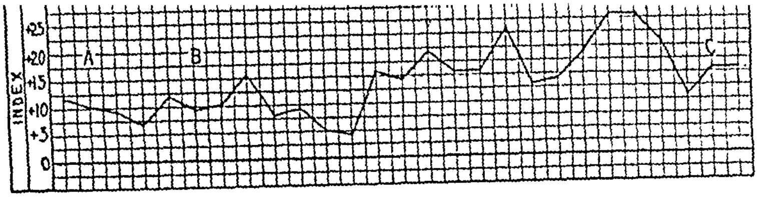

Chart 2 (Case 6).—Positive index of resistance in an uneventful convalescence in influenzal pneumonia: *A*, improving; *B*, good; *C*, lungs clear.

5. In cases between the fourth and eleventh days, the resistance line is of great value to the surgeon in indicating the patient's poor resistance and the necessity for immediate operation. The operative findings in the cases bear out the leukocyte determination with wonderful accuracy.

6. A horizontal or falling resistance line indicates that the patient is taking care of the infection. If the infection is severe, as shown by a high though falling line, the patient may perhaps best be given medical treatment rather than submitted to operation.

After further study of this subject, Sondern,[4] in a later paper, made the following observations which are significant in considering a blood picture from the point of view in question:

> The increase in the relative number of polynuclear cells is an indication of the severity of toxic absorption, and the degree of leukocytosis is an evidence of body resistance toward infection.
>
> Purulent exudates were rarely if ever present with low polynuclear percentage irrespective of the height of the leukocyte count, while high polynuclear percentages almost invariably indicated their presence, even if the total leukocyte count was low.

He also noted the following exceptions to the foregoing statement:

1. Children present a more variable normal polymorphonuclear percentage, and therefore Gibson's resistance chart is not applicable to them.

2. In conditions in which pus is confined so that no toxic absorption occurs, or when the purulent exudate is of tuberculous or typhoid origin, there is no leukocytosis and no polymorphonuclear increase.

3. Mixed infections with or following tuberculosis or typhoid does not show as high polymorphonuclear percentage as primary streptococcic or staphylococcic infections.

4. The exact nature of infection has direct bearing on the degree of polymorphonuclear increase, some organisms causing a higher percentage than others.

THE INDEX OF RESISTANCE

Sondern's hypothesis as applied by Gibson and modified by Wilson deserves a wider application and more general utilization in interpreting blood pictures. Perhaps the chief reasons that it has not been used are that the work is not generally known, and that such interpretation depends on the presence of the "standard chart." As these charts are not always at hand, and if used, require an extra sheet on the hospital record with that added expense, this very valuable aid has been neglected.

The "resistance line" is simply a visual expression of the disproportion between the total leukocyte count and the polymorphonuclear percentage, starting with the normal figures for these factors, and assuming that they normally increase in the ratio of 1 per cent. of polymorphonuclears to 1,000 total leukocytes per cubic millimeter. Therefore, we can express the same thing in the formula.[5]

$$(T-10)-(P-70)=\text{I. R.}$$

T is the digits in the thousandths place in any given leukocyte count; 10 is the digits in the thousandths place in the high normal leukocyte count; *P* is any given polymorphonuclear percentage; 70 is the high normal polymorphonuclear percentage; I. R. is the "index of resistance."

Example A:
Total leukocyte count.........15,000
Polymorphonuclear percentage.. 80
$(15-10)-(80-70)=-5$ I. R.

Simple mathematics reduces the foregoing formula to:

$$T-(P-60)=\text{I. R.}$$

Example A:
$15-(80-60)=15-20=-5$ I. R.

Example B:
Total leukocyte count.........25,000
Polymorphonuclear percentage.. 75
$25-(75-60)=+10$ I. R.

Example A would correspond to a rising resistance line, and Example B to a falling resistance line on the "standard chart."

In example A there is a disproportionate increase in the polymorphonuclears, or in other words, the severity of the infection is comparatively greater than the reaction of the body to it, with a consequent "negative index." In Example B there is a good reaction to a comparatively mild infection, with a resultant "positive index."

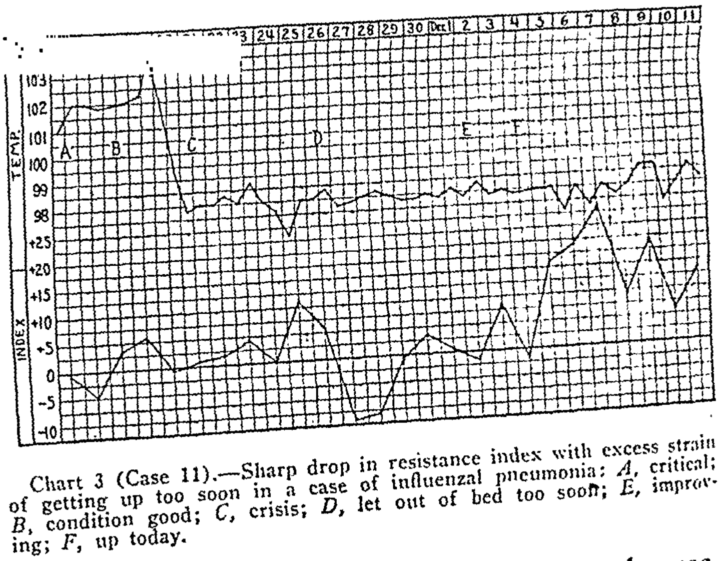

Chart 3 (Case 11).—Sharp drop in resistance index with excess strain of getting up too soon in a case of influenzal pneumonia: *A*, critical; *B*, condition good; *C*, crisis; *D*, let out of bed too soon; *E*, improving; *F*, up today.

Although there is a rather wide range in what is considered normal total leukocyte and polymorphonuclear counts, it was thought best to consider 10,000 as the extreme upper limit of normal total white count, and 70 per cent. as the corresponding polymorphonuclear normal.

---

[4] Sondern, F. E.: The Value of the Differential Leukocyte Count in Diagnosis, Am. J. M. Sc. **32**: 889 (Dec.) 1906.

[5] Some time previous to my entrance into the army, Miss Marie Bump and I, at the Bierce Memorial Laboratory, St. Anthony's Hospital, Oklahoma City, evolved a formula which in a single figure essentially expresses the same thing as the "resistance line" of Gibson and Wilson.

Use of the formula *T*—(*P*—60)=I. R. gives one a quick and tangible interpretation of a blood picture in any acute inflammatory process. The positive or negative figures can be entered on a record sheet in a vertical column from day to day, and a glance down the column quickly gives one an idea of the blood resistance index. Or the index figure may be plotted daily along with temperature, pulse and respiration, and so produce a graphic picture corresponding with these signs (Chart 1).

At any time one can readily calculate mentally the index from any white and differential count, and thus quickly decide the diagnostic or prognostic value of the blood picture.

Although this study includes no observations in acute surgical cases, the index is obviously of the same value in this class of cases as the Gibson "standard chart." As this has already been used extensively and the statements of the early workers corroborated, it was not thought necessary to include any such cases here.

This study includes observations in 105 cases of various diseases, thus distributed: pneumonia, forty-six; influenza, thirty-five; empyema, twelve; measles, twelve.

The work was begun with the purpose of determining the value of the index of resistance as an aid in prognosis, and in the early detection of complications, such as empyema and otitis media. Incidentally, other interesting observations have been made.

Daily total leukocyte counts and differentials were made in each case for periods varying from three to sixty-five days. Counts were begun on the same day the patient entered the hospital in nearly all cases, and the study was terminated either by death of the patient or dismissal from the hospital; or, the convalescence being well advanced, it was considered unnecessary to follow the case farther. Eight large squares on a Levy hemocytometer were counted in the estimation of the number of total white cells, and 300 cells were counted in each differential. Particular attention was given to obtaining even, uniform blood smears. Blood was collected at approximately the same time each day from any given patient, thus ruling out any changes that might arise due to exercise, meals, baths, etc. Our patients were all men between the ages of 21 and 31 years. Each day the clinical condition temperature, pulse and respiration were checked up with the blood findings. Altogether 1,710 total leukocyte and 1,710 differential counts were made.

RESULTS IN PNEUMONIA

Of the forty-six pneumonia patients observed, seventeen died, twenty made a more or less uneventful recovery, and the remaining nine developed complications and intercurrent infection. Of those who died, four developed empyema during the course of the pneumonia.

In all cases of uneventful recovery, the index became positive and remained so (Chart 2). Often this was quite high early in convalescence, but gradually came back toward the normal.

In seventeen cases terminating in death during the acute stage of the disease, the index was very markedly negative, and in general the lower the index the more critical the condition of the patient appeared. In most instances, this negative index continued to the end. However, in six out of seventeen deaths, there was observed a sharp and marked antemortem rise to positive. This occurred usually from twenty-four to forty-eight hours prior to death.

In the event of an intercurrent infection occurring during convalescence, or the onset of a complication, a positive index suddenly became negative and remained so for several days before the body apparently won the battle and the index again rose to plus. A similar phenomenon was seen in a case in which the patient was allowed out of bed too soon (Chart 3). In cases of empyema or purulent otitis media which were undrained for some time, the index curve was of an irregular saw-tooth character, rising above and dropping below the zero line, not unlike a septic temperature curve (Chart 4). With complete drainage, the curve rose to positive.

The blood index is as sensitive an indication of trouble as the temperature curve or other clinical signs. A negative index was observed coincidentally with a rise of temperature in a number of cases, and often slightly before the temperature was affected. Moreover, in convalescents who were not improving as rapidly as was expected, a hyperleukocytosis and a negative or irregular index were noted to persist long after the temperature, pulse and respiration had become normal. Often, no other signs of trouble could be found besides the blood picture and the apparent

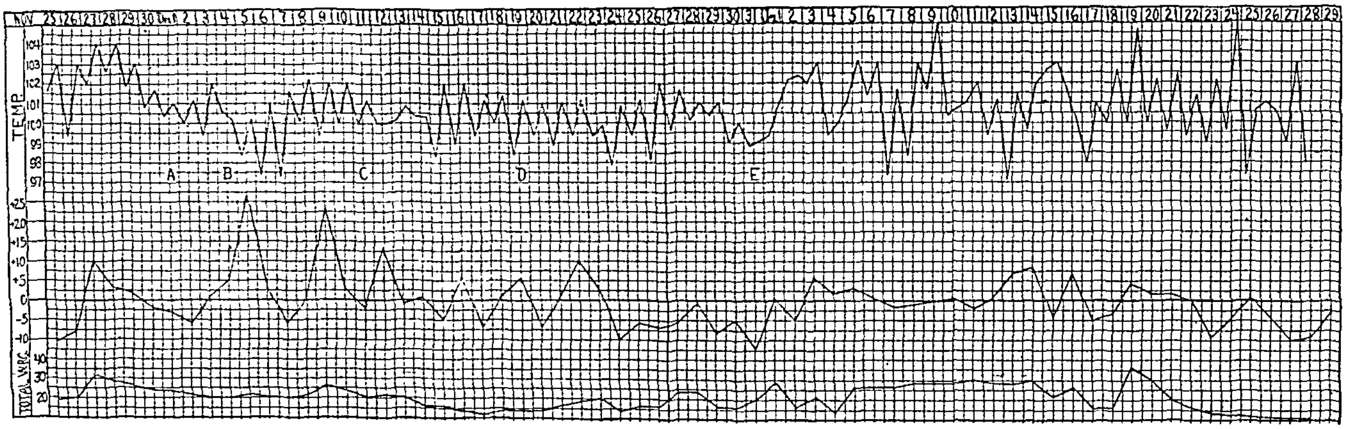

Chart 4 (Case 16).—Temperature, index of resistance, and total leukocyte count in a case of influenzal pneumonia with complications of acute suppurative otitis media and bilateral empyema: *A*, discharge from right ear; *B*, paracentesis, right ear; *C*, swelling and pain in right leg; *D*, no fluid on aspiration; *E*, pus on aspiration and costatectomy discovered clinically. At necropsy there was bilateral empyema; one side undrained.

lack of response on the part of the patient (Chart 1). This feature was noted particularly in influenza and measles cases.

RESULTS IN INFLUENZA AND MEASLES

The blood picture in these two conditions was so similar that we can easily discuss them together. Development of complications or the onset of other mild infections, such as bronchitis, alveolar abscess, tonsillitis and arthritis, was marked by a sudden drop of the leukocytic index to negative, returning in a few days to positive, apparently as the resistance of the individual increased and overcame the infection (Chart 5). In these conditions, a negative index was frequently seen to persist for days after the temperature, pulse and respiration became normal. This occurred in that class of individuals who do not "pick up" readily after measles and influenza, but continue weak and languid and altogether "below par." As these patients improved, the index gradually rose to positive (Chart 1).

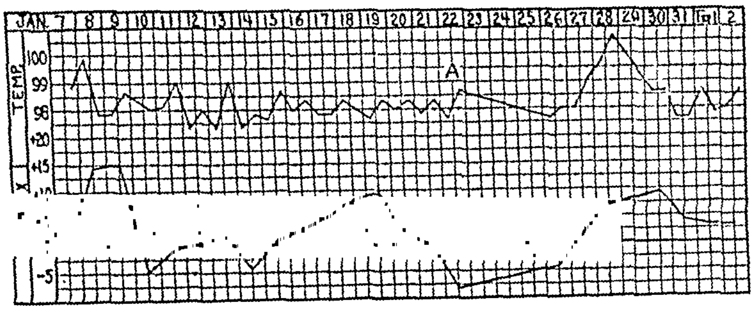

Chart 5 (Case 69).—Index the first sign of trouble in a case of influenza with arthritic complications: *A*, arthritis, discovered clinically.

Early in influenza and measles the total leukocyte count was normal or slightly reduced. Only one in thirty-five cases of influenza and two in twelve cases of measles showed a hypoleukocytosis below 5,000 per cubic millimeter. On the other hand, after the disappearance of the acute symptoms and during convalescence, it was not unusual to find the count ranging anywhere from 12,000 to 25,000 cells per cubic millimeter. Parallel to this the temperature, pulse and respiration were normal, or nearly so, and in most cases no cause for the hyperleukocytosis could be found. In a few cases, mild infections, such as chronic catarrhal pharyngitis, chronic tonsillitis, and chronic apical abscesses about the teeth, were the only apparent cause. Influenza and measles appear to render the hematopoietic organs very sensitive to even the slightest stimuli from the mildest infections, to which they respond with unusually high production of polymorphonuclear cells.

RESULTS IN EMPYEMA

In empyema that was draining well and in which the body was overcoming the infection, the blood index remained steadily positive. However, if an acute disease, such as tonsillitis, occurred during such a convalescence, the index dropped suddenly and often before any other signs appeared (Chart 6). In cases of incomplete drainage, such as those with walled off pockets, or clogging of the drainage tube or its displacement, the index was prone to simulate a septic temperature curve.

Eosinophilia was a rather common occurrence in our empyemas. In seven out of fourteen cases, eosinophils appeared in percentages varying from 6 to 31.

COMMENT

It is estimated that with the most careful and skilful technic, the factor of error in the total white count is about 5 per cent. With careful, even preparation of smears, the error of differential counting is no more than 2 per cent. Allowing for these factors of error, there should be a variation of no more than three or four points from day to day in the index, other things being equal. Practically, there is actually a daily fluctuation of from five to eight points, which must be considered in the interpretation of any given blood picture. There is probably a slight normal variation from day to day in the total leukocyte and polymorphonuclear count for any given individual. Generally speaking, the greater the departure from the normal, the more significant the index. Also, just as a single temperature observation is of comparatively small value in judging the course of any given condition, so a single blood picture is not to be relied on. A daily blood picture is ideal, but may encounter objections on account of the large amount of work involved. However, an index determination every second or third day during the course of the acute infectious diseases is desirable and not at all unreasonable.

There is a very wide variation in the absolute response of the leukocytes to any infection independent of the severity of the infection, and therefore the total leukocyte count when taken alone is of little or no value in getting at the exact condition of the patient, or the degree of the infection.

It might be well to warn against dogmatic dependence on the index alone. It should be used only as a *factor in completing* the study of any given case, and should always be considered in the light of other clinical and laboratory findings.

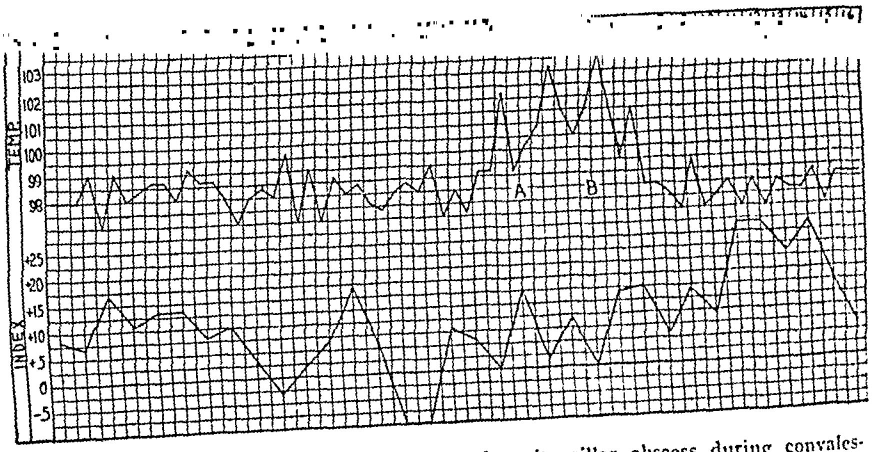

Chart 6 (Case 4).—Empyema; tonsillitis and peritonsillar abscess during convalescence; negative index four days before other signs of tonsillitis; *A*, tonsillitis; *B*, peritonsillar abscess.

I feel that this study has not been exhaustive enough to determine the true value of the leukocyte index in pneumonia, influenza, measles and empyema, and this report is made with the hope that others will help by trial in this determination and possibly find assistance in its application.

CONCLUSIONS

When used alone, neither the total leukocyte nor the differential count will give the examiner a true idea of the degree of an infection or the condition of the patient.

Sondern's hypothesis that the proportional relation of the total leukocytes and the polymorphonuclear percentage is an index of body resistance seems to be true.

A ready and tangible method of determining the degree of resistance from the leukocytic examination, that is, total leukocyte and polymorphonuclear percentage, is afforded by the index of resistance, which expresses essentially the same thing as Gibson's "resistance line," but is a more accessible means of interpreting a blood picture than the "standard chart."

The index of resistance has the same value in acute surgical conditions as Gibson's "resistance line."

The blood index is as sensitive an indication of change in the condition of an acute inflammatory process as the temperature curve and other clinical signs. In some instances it has seemed to be more delicate than any other sign.

In acute infectious diseases, such as pneumonia, influenza, and measles, the leukocyte index is of value chiefly as a danger signal of the onset of septic complications. The lower and more persistent the index, the more certain is the sign and the more serious is the condition.

THE BLOOD PICTURE OF THOSE INOCULATED WITH INFLUENZA VACCINE *

GUTHRIE McCONNELL, M.D. (Philadelphia)
Major, M. C., U. S. Army
NEW HAVEN, CONN.

One of the most widely discussed questions at the present time is the relation, if any, that exists between *B. influenzae* (Pfeiffer's bacillus) and the recent pandemic. From the bacteriologic point of view it would seem that many investigators throughout the world have serious doubts as to the etiologic significance of the influenza bacillus in this condition. Many believe that some form of micrococcus is the exciting agent, while other well-known men, such as Hektoen and Vaughan, state that it is "a disease of unknown origin."

In the clinical reports of the epidemic, the majority of observers agree as to the presence of a more or less well-marked leukopenia. Little, Garofalo and Williams[1] report that the present epidemic is not characterized by a sharp leukocytosis and polynucleosis, but rather by a very slight leukocytosis with a proportional lymphocytosis of the small mononuclear variety. Keegan,[2] in the examination of twenty-eight early cases from the first to the fourth day, found an average count of 6,700 white blood cells with 63.7 per cent. polymorphonuclears and 33.3 per cent. lymphocytes. He states that the white blood cell count in uncomplicated cases is below the normal. Nuzum, Pilot, Stangel and Bonar[3] noted that blood counts taken early after the initial symptoms exhibit a striking leukopenia as low as 1,800 and averaging from 3,000 to 4,000. With the onset of pneumonia, a definite leukocytosis quite commonly appears. Strouse and Bloch[4] note that a leukopenia was the rule, except when an empyema developed. Keeton and Cushman[5] report that influenza has a high (46.6) percentage of leukopenia in the early stages. Blanton and Irons[6] made white blood cell counts in 580 cases in the prepneumonia stage, of which 70 per cent. showed less than 8,000 white cells. This leukopenia was the most impressive feature of the blood count. The polymorphonuclears showed but slight increase over the normal, nor was there any conspicuous lymphocytosis. Of 1,000 white cell counts in pneumonia patients, 67.5 per cent. showed 8,000 or less. Ely, Lloyd, Hitchcock and Nickson[7] state that of seventy-five white cell counts, twenty-five gave 5,000 or less, thirty-four between 5,000 and 10,000, and sixteen over 10,000. Brem, Bolling and Casper[8] found that in the influenzal stage leukopenia was practically always present, and at first it appeared to be a feature of the pneumonia stage. The average count in eighty-six influenza cases was 6,000, and in 148 pneumonia cases 6,800. Synnott and Clark[9] made counts in more

TABLE 1.—RESULTS OBTAINED IN ONE HUNDRED AND FIFTY-EIGHT CASES AT VARYING PERIODS AFTER INOCULATION

Character of Case Counted	Number of Cases	Average Age	Total: Red Blood Cells	Total: White Blood Cells	Differential: Neutrophils	Differential: Eosinophils	Differential: Basophils	Differential: Lymphocytes	Differential: Mononuclears

than 700 cases and found an absence of leukocytosis in the more severe ones, and during the acute stage of those running a more favorable course. The average white cell count during the acute stage was about 5,000, the lowest recorded being 1,200. Gotch and Whittingham[10] found a distinct leukopenia (3,000 to 4,500) at the height of the fever. Cole[11] found that there was usually a leukopenia of from 2,400 to 9,000 in purely toxic cases, and even in extensive bronchopneumonia.

TABLE 2.—RELATION EXISTING BETWEEN THE DEGREE OF REACTION AND THE BLOOD CHANGES

Reaction	Cases	Per Cent.	White Blood Cells	Total Polymorphonuclears	Total Mononuclears	Age	Days After Inoculation
++	16	11.2	8,765	66.5	33.5	32.2	7.9
+	7	4.9	7,890	65.0	35.0	29.5	8.4
±	21	14.7	8,647	66.3	33.7	30.5	11.0
No reaction	99	69.2	8,563	65.2	34.8	26.5	9.0

In averaging, as well as possible, the figures given in the foregoing quotations, we get a white blood cell count of approximately 5,700 per cubic millimeter. As one of the methods employed in combating this epidemic was the use of an influenza vaccine made up of numerous strains, it was thought that some information might be obtained by making white cell counts of those who received the vaccine. If the primary infecting agent was the bacillus of Pfeiffer, and if, according to the clinical reports, such infection was accompanied by a leukopenia, it would seem logical to suppose that the injection of the organisms should cause a more or less similar reaction.

TABLE 3.—DISTRIBUTION OF WHITE CELLS IN FORTY-EIGHT OFFICERS

Number of Cells	Counts	Per Cent.
Below 6,000	5	10.4
6,000 to 7,000	4	8.3
7,000 to 8,000	17	35.4
8,000 to 9,000	6	12.5
9,000 to 10,000	5	10.4
10,000 to 12,000	5	10.4
12,000 and up	6	12.6
Total	48	100.0

Average age, 34.9 years.
Days after inoculation, 10.98.

TABLE 4.—DISTRIBUTION OF WHITE CELLS IN ONE HUNDRED AND TEN ENLISTED MEN

Number of Cells	Counts	Per Cent.
Below 6,000	5	4.5
6,000 to 7,000	22	20.0
7,000 to 8,000	32	29.0
8,000 to 9,000	21	19.1
9,000 to 10,000	10	9.1
10,000 to 12,000	13	11.8
12,000 and up	7	6.5
Total	110	100.0

Average age, 24.7.
Days after inoculation, 7.71.

The present report gives the results of blood counts made in 158 cases—110 enlisted men and 48 officers. Of this number, 143 were apparently normal individuals who had received the influenza inoculation. Of the remaining fifteen, there were eleven who had had influenza, three who had had influenza and the inoculation as well, and one who had had neither the disease nor the inoculation. This work was done during November, 1918, at the Yale Army Laboratory School, New Haven, Conn., Col. Charles F. Craig, M. C., in command.

From an examination of the accompanying tables, it would seem that there was little effect, if any, on the total count of white cells, or on their relative percentages. Nor does the length of time intervening after the inoculations make any difference. There also seemed to be no relationship between the severity of the reaction and the number of white cells, those having no reaction giving practically the same average as those having the most severe.

TABLE 5.—FINAL AVERAGES OF DISTRIBUTION OF WHITE CELLS FOR TOTAL OF ONE HUNDRED AND FIFTY-EIGHT COUNTS MADE

Number of Cells	Counts	Per Cent.
Below 6,000	10	6.3
6,000 to 7,000	26	16.4
7,000 to 8,000	49	31.0
8,000 to 9,000	27	17.1
9,000 to 10,000	15	9.5
10,000 to 12,000	18	11.3
12,000 and up	13	8.3
Total	158	100.0

Average age, 27.8 years.
Days after inoculation, 8.73.

The final average gave a total of 10,000 white cells per cubic millimeter for the officers, and 7,700 for the enlisted men.

A study of the tables would indicate that *B. influenzae* when injected subcutaneously into an individual does not have any effect on the tissues concerned in the formation of the white cells. That it is not due to a lack of effect on the individual is shown by the fact that even in those instances in which there was a marked constitutional reaction there were still no changes in the blood picture. Since the general opinion of clinicians is that a leukopenia is one of the characteristic findings in the recent epidemic, it would seem justifiable to consider the findings here reported as an additional argument against the bacillus of Pfeiffer being the causative agent.

TABLE 6.—SUMMARY OF FINDINGS IN THE ONE HUNDRED AND FIFTY-EIGHT CASES EXAMINED

Character of Cases Counted	Number of Cases	Average Age	Total		Differential				
			Red Blood Cells	White Blood Cells	Neutrophils	Eosinophils	Basophils	Lymphocytes	Mononuclears
Total	158	27.8	4,940,000	8,451	63.6	1.4	0.3	32.1	2.6
Inoculations only	143	27.9	4,944,000	8,565	63.9	1.4	0.2	32.0	2.5
Not inoculated	15	27.1	4,896,000	7,374	62.1	1.6	0.1	33.1	3.2
Total officers	48	34.9	5,125,000	10,000	65.6	0.4	0.2	31.5	2.3
Total enlisted men	110	24.7	4,859,000	7,776	63.0	1.8	0.3	32.4	2.7

Counts taken on officers on average of 10.98 days after last inoculation.

Counts taken on enlisted men on average of 7.71 days after last inoculation.

Beginning of Epidemics.—Consider every case of typhoid you discover as the first one of an epidemic.—*Weekly Bulletin, A. E. F.*

Clinical Notes, Suggestions, and New Instruments

A ONE-PIECE SURGICAL OPERATING SUIT

W. Wayne Babcock, M.D., Fort McPherson, Atlanta, Ga.
Lieut.-Col., M. C., U. S. Army

All surgeons have doubtless experienced the inconvenience of having buttons drop off of operating suits at inopportune moments. Some may have also found separate trousers a disadvantage. To such the one-piece suit here described and illustrated will surely appeal. This one-piece suit has no buttons, but is secured by two tapes. It is adjustable to considerable variations in size, although in a large service it may be well to provide two sizes. The idea for this garment was developed by Mrs. T. H. Hinman and the supply was furnished by the Atlanta branch of the Red Cross. We feel greatly indebted to the designer and to the Red Cross for developing and supplying us with this garment, which we find very useful and convenient.

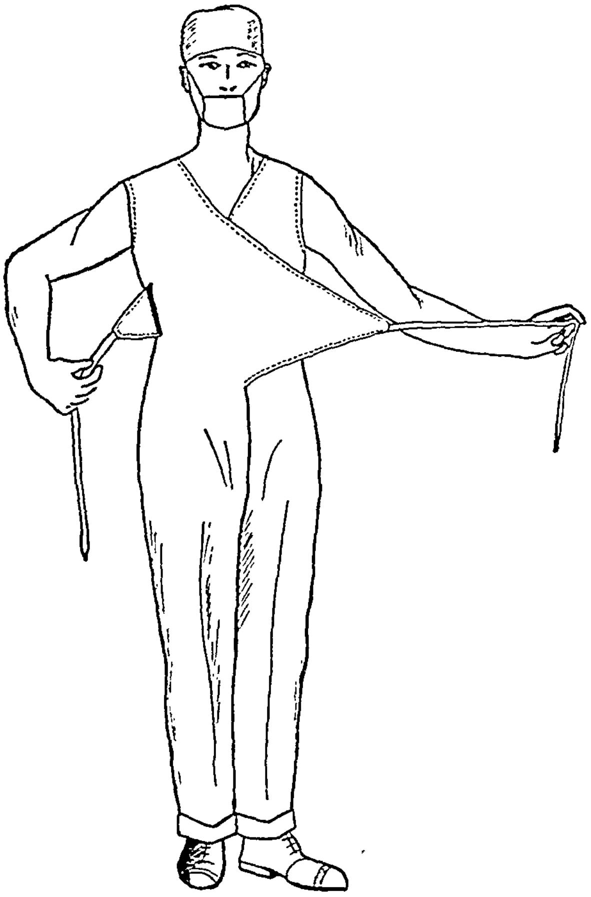

Fig. 1.—The manner of securing the one-piece surgical operating suit by two tapes.

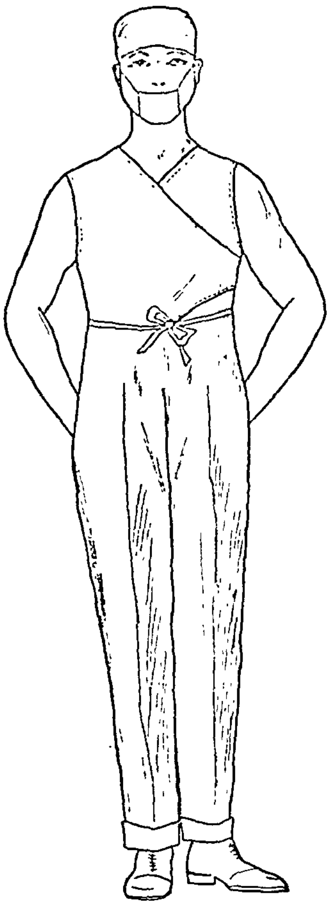

Fig. 2.—The manner of tying the tapes in front.

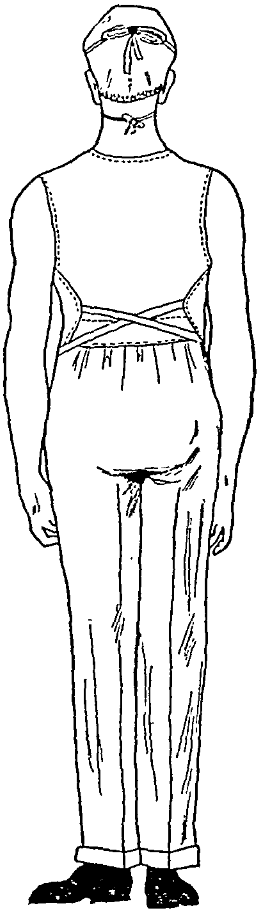

Fig. 3.—The manner of adjusting the tapes at the back.

TUBERCULIN TREATMENT OF TUBERCULOUS EPIGLOTTIS

Herbert F. Gammons, M.D., Carlsbad, Texas

The tissue changes resulting from injection of tuberculin in or near tuberculous foci have been most remarkable in some instances.

White and Marcy[1] report good results from such treatment of a tuberculous tongue; Patterson[2] gives his final results in eye conditions treated similarly, and Pottenger[3] remarks on the good results obtained in laryngeal cases treated by tuberculin locally.

The following case is of interest and study of similar cases may help us to get a better understanding of immunity in tuberculosis:

S. A., showing a moderately advanced case running normal temperature and pulse, complained of irritation in the throat. Examination of the larynx revealed a localized area of inflammation on the upper right of the epiglottis posteriorly. This was treated with different local applications, but regardless of treatment the area extended and ulceration with slight edema resulted. Amputation was considered, but it was thought best first to try tuberculin.

March 15, 0.00001 mg. bacillary emulsion was injected at the base of the ulcer. In twenty-four hours there was a slight local reaction with some swelling and redness and slight elevation of temperature. Four days later 0.0001 mg. of the same variety of tuberculin was injected. One week later 0.001 mg. of the same variety of tuberculin was injected. In twenty-four hours a marked general and local reaction resulted. The epiglottis was markedly swollen, deglutition was difficult and temperature went to 104 F. Fever rapidly subsided as did the swelling in the epiglottis. The ulcerated area is now covered with new epithelium, and there is no evidence of acute inflammation. The epiglottis on the right side is a trifle thicker, but there are no subjective symptoms referable to the larynx. The patient's general condition is better than before the reaction. The patient was taking artificial pneumothorax at intervals during the treatment.

HOSPITAL SERVICE IN RURAL COMMUNITIES

A PRELIMINARY REPORT

Prepared by Ernst C. Meyer, Director of the Department of Surveys and Exhibits of the Rockefeller Foundation International Health Board

New York

(Concluded from page 1367)

PART IV. LEGISLATION CONCERNING RURAL HOSPITALS

LAWS MAKING THE ESTABLISHMENT OF COMMUNITY HOSPITALS OPTIONAL

Iowa was the first state to pass a law allowing counties to tax themselves for the purpose of providing hospitals. The Munger bill, passed in 1909, provides that any county by a vote of its electors may levy a tax for the building, equipment, and maintenance of a county general hospital for the care of all classes of the sick, particularly the tuberculous.

Michigan, in 1909, also passed a law allowing county supervisors to raise a tax for constructing or maintaining or assisting to construct and maintain a hospital or sanatorium. In 1913, this law was amended so that 5 per cent. of the county electors could petition the supervisors to issue bonds and levy a tax for establishing and maintaining a public hospital. Such a petition then required submission to a general vote.

Indiana passed a state law in 1913 allowing the necessary funds for county hospitals to be raised by a tax levy and bond issue. In the same year, North Carolina permitted counties to vote on bond issues for the establishment of county or community hospitals. In 1915, Kansas passed a law along similar lines which allowed cities with the commission form of government, and with a population of from 3,000 to 6,000, to levy a tax for equipping and maintaining a hospital. Missouri, New York, and South Carolina have enacted laws resembling that in force in Iowa. The New York state law is a township law. In addition, Colorado, Idaho, Maryland, Montana and Vermont have passed laws authorizing cooperation in hospital construction on the part of different counties, cities, and towns.

LAWS MAKING THE ESTABLISHMENT OF COMMUNITY HOSPITALS COMPULSORY

A compulsory law for the establishment of county hospitals was passed in Texas only. This law, enacted in 1913, makes it mandatory for counties of more than 20,000 population to build and operate general hospitals, and compels them to tax themselves. Counties of less than 20,000 are permitted to join with other counties, taxing themselves pro rata to help pay for both hospital construction and operation.

EFFORTS TO SECURE LEGISLATION CONCERNING HOSPITALS

The people of Mohave County, Arizona, at a recent election adopted a resolution petitioning the state legislature to pass a law authorizing county boards to establish hospitals in which persons, whether able or unable to pay for treatment, might be accepted.

The Northwestern Nebraska Medical Society recently petitioned the legislature of the state to enact a measure enabling cities of the second class to vote bonds and levy a tax for the establishment of hospitals. The proposed measure is modeled on the Iowa county hospital law except that it enables municipalities instead of counties to erect and operate the hospitals.

Pennsylvania has introduced a bill for the establishment of a cottage state hospital at Honesdale. South Dakota and Utah have drafted bills for the establishment of county hospitals. It was also reported that the legislature of Utah would be called on to consider a county hospital bill.

POPULAR ACTION UNDER HOSPITAL LAWS

Nov. 8, 1910, eight counties in Iowa asked for a vote concerning hospitals. Washington County was the only one that succeeded in having the tax levied. The hospital is reported to have been a success from the start. In the same year that the Washington County Hospital was opened, a further county hospital was being built for Jefferson County. Up to December, 1916, so far as is known, the hospital issue was before the people for a vote in twenty-two counties. It was defeated in twenty counties and carried in the two counties mentioned above.

It is not known what progress was made in Michigan. Indiana has two county hospitals, at least one of which, the Bartholomew County Hospital, was opened in December, 1916, shortly after the bill had passed. Kansas has two county hospitals, but it is not known whether they were opened before or after the passing of the law. The same applies to the Anderson County Hospital in South Carolina. In North Carolina, two counties (North Hampton and Pitt) waged campaigns but lost the election. In one county (Lenoir) the bond issue was voted. No hospitals had been built in this state up to March 7, 1917.

According to latest reports, the compulsory hospital law in Texas was in full operation. The law specified that the following cases were to be cared for in these hospitals; medical, surgical, gynecologic, obstetric, children, tuberculosis, and the communicable diseases. Construction of hospitals of this type is now under way in various parts of the state.

PART V. SOME THINGS THAT NEED TO BE KNOWN TO SOLVE THE COMMUNITY HOSPITAL PROBLEM

In its simplest elements, the hospital problem resolves itself into two parts: provision of the hospital plant in which service is to be rendered, and provision of the services for which the plant is created. The provision of the plant in turn resolves itself into two subsidiary problems: How large shall the building be, that is, how many beds should the hospital contain, and where should it be located? A correct answer to the first question is desirable in order that there may be economy in the use of funds. A correct answer to the second question is desirable in order that the community may be served with the least possible waste in time and money, and the smallest individual inconvenience or effort. In seeking an answer as to the size of the building, it is necessary to gain a definite idea concerning the extent of hospital needs. This presupposes, first, a sickness rate formula, and second, a hospital case formula, the latter obviously being dependent on the former. Unfortunately, as emphasized in Part I, little information is at present available concerning either the rate of sickness or the proportion of all cases of sickness that should have hospital treatment. Estimates and guesses have frequently been made, but they are not based on definite statistical data.

Before a correct sickness rate formula can be worked out, it will be necessary to secure facts which will serve to indicate the trend of sickness in the future. A hospital is not a thing of a day. It is intended to endure through many years, and even generations. Decrease or increase in sickness, were it to follow a definite course, might be a matter of serious import in the original planning of the building.

It is well known that the trend of the death rate among modern civilized populations is steadily downward. It would seem to follow that the sickness rate will likewise continue to be downward. There are, however, numerous uncertain elements. The speed of this downward tendency, as is obvious, will depend, among other things, on the accomplishments of scientific medicine and their application in a practical way, both through the medium of the private practicing physician and of the public health officer. Striking results have been secured in the recent past. It is not unlikely or improbable that further startling advances will be made particularly in the control of communicable disease. All calculations as to the extent of the need of hospital facilities may be upset. Increased ability in the control of constitutional diseases, and the elimination of chronic cases, coupled with the awakening of the population to the importance of these diseases, may also radically affect any hospital case formula that might be established at the present time.

In establishing a hospital case formula, numerous other difficulties are encountered. Whether or not a given case needs hospital care may depend on many factors—nature of sickness, availability of physician's care or of nursing care, home conditions, the ability of the patient to stand transportation, the distance of transportation, etc. Any hospital case formula which might be established would need to be modified to suit a particular community, and to meet the peculiar conditions that may prevail there. Clearly, communities differ in matters of health as in matters of wealth, and in other things. The most important factors to be considered are the death rate, character of population with respect to wealth, probable increase or decrease in the population of the area to be served, social conditions, percentage of the foreign group, degree of prejudice against hospital service, character of industries and industrial diseases, prevailing types of general diseases, etc.

A reasonable answer to the question of the size of a hospital plant is of importance mainly in two ways. If the plant is too small, the services it can render will not be complete. There are apt to be unnecessary deaths in the community, some unnecessary prolongations of sickness, and some unnecessary temporary or permanent disabilities. If, on the other hand, the plant is built too large, money will have been wasted in its construction, and money will continue to be wasted in its maintenance as long as the building stands.

LOCATION OF HOSPITAL

The problem of location is second only to that of size and arrangement. It is a matter that cannot be lightly disposed of, although abundant instances appear on record in which little thought has been given to it, and in which the whim or prejudice of some local philanthropist has fixed the place to put it. Attention need be given to the location of other hospital facilities and their character, together with the extent to which they draw on local needs; the distribution and shifting of population together with possible increase and decrease; the convenience of the medical profession, and the promptness of medical aid in emergency; current transportation facilities, with forecast of future developments; topography and healthfulness of the region; and proximity of industrial enterprises.

MAINTENANCE

Of equal importance with the mere establishment of a plant is provision for its maintenance; yet it has been the history of small hospitals that adequate provision for maintenance has frequently not been made, with the result that many of them have soon found themselves on the rocks, and have dragged through discouraging years, too weak financially to be properly equipped and maintained, and with too inadequate service to attract the revenues which might keep them on their feet. From what facts are available in the printed records, few hospitals have encountered serious difficulties when proper provision for their maintenance has been made.

RENDERING HOSPITAL SERVICE

Considerable difference of opinion appears to prevail as to the best organization of medical service of the community hospital. There are advocates of the so-called "closed staff" system, under which the hospital medical service is administered by a permanent paid staff which takes care of all patients brought to it. Others favor the "open staff" system, under which any physician of the community may bring his patient to the hospital and continue his care until convalescence or death. There are also modifications of these two systems under which a hospital superintendent, often a surgeon, and occasionally certain assistants, supervise all medical service within the hospital, and strive in varying measure to secure certain standards of service.

According to the history of hospitals thus far established in small communities, the solution of the hospital staff question seems to be one of the most difficult that confront hospital administrators. This arises largely from the fact that the good will and cooperation of the local medical profession is almost a sine qua non for hospital success. If the statements of medical men themselves may be taken at face value, it would seem that nowhere is prejudice, envy and petty policy so rampant as among small town physicians.

PART VI. HOW SOME OF THE INFORMATION NEEDED TO SOLVE THE COMMUNITY HOSPITAL PROBLEM MAY BE SECURED

From what has been said, it would seem that adequate standards on the strength of which hospitals may be established and operated in rural communities are still largely to be created. Various steps suggest themselves by which the fundamental data that are necessary for this purpose may be provided.

1. The experience of existing community hospitals may be studied. This would include a study of the

methods used in establishment and administration, attitude of the public, patronage, and above all a careful investigation into the case history of the hospital through an extended period of time to throw light on the growth and change in the hospital needs of the locality. The International Health Board has on file a fairly complete statement (as of January, 1918) of small hospitals in operation in all parts of the United States, together with a further statement on such hospitals as have been planned, or the establishment of which is being agitated in various communities.

2. In carefully selected communities, experiments might be conducted through the construction of typical community hospitals, coupled with a close study of community health conditions and hospital needs of individual cases of sickness, as well as the numerous other factors concerning which information appears desirable.

3. Community surveys could be made to supply a large basis of statistical fact concerning the extent and character of sickness, with particular reference to its relation to the extent of hospital care needed by the sick. This information could be collected only through personal visits to the homes of the sick and careful investigation of all facts surrounding each case. Such work obviously would need to be in the hands of a competent investigator who was able to secure access to cases of sickness and to receive complete information with regard to them. It is believed that where such a survey is planned, the rural home visiting nurse would deserve close consideration as an effective enumerator. A number of important advantages at once come to mind:

1. The nurse can gather statistical data in the course of her regular duties. Being a by-product of her regular work, the survey would not be expensive. This method would also be a diplomatic way of getting information. The community will not be likely to feel that it is being made the object of "high-brow curiosity," as has so often been the case in the conduct of social investigations. The visit of the nurse will be in the spirit of a service, not of a study.

2. The nurse would also be in a position to follow each case with greater care, and by use of more time than could be devoted to it by a special enumerator whose effort would probably of necessity have to be limited to a single call. Repeated visits would tend to eliminate errors and in other ways increase the accuracy of the record.

3. Where surveys have been attempted it has been found that frequently reluctance is shown in giving information. The nurse, as a welcome attendant of the sick, would be apt to encounter open hearts and minds and complete confidence, such as would not be accorded an enumerator, no matter how tactful, who was unknown to the family approached.

4. Overshadowing in many respects the considerations already set forth is the fact that the actual hospital needs of a community can hardly be accurately determined without first ascertaining what cases of sickness may be properly cared for in the home. Information has already been presented which shows that 65 per cent. of the cases of sickness studied are cared for in homes. The work of the home-visiting nurse will serve to demonstrate what cases at present cared for in homes should be cared for in hospital, and vice versa. Nowhere does it seem to have been found wise to seek to drive a maximum number of cases of sickness into hospitals. Hospital care is always expensive because the plant is expensive and the space is comparatively limited. The home is the logical place for the care of the sick who can be cared for there. It is also the most economical, the most satisfactory, and the sort of care which, other things being equal, gives promise of quickest recovery. The work of an efficient home-visiting nurse will serve to delimit the sphere of home care, on the one hand, and of hospital care, on the other.

5. An exceedingly important by-product in the form of favorable public sentiment is also likely to result when a survey made with a view to the possible establishment of a hospital is conducted by a home-visiting nurse. It seems to be generally conceded that, as an efficient educational force, practical daily demonstrations by a tactful and helpful home-visiting nurse can hardly be excelled. Nothing teaches like demonstration. The nurse will deal with the raw material of the future hospital, and can drive home her arguments with a convincing certainty. A death that might have been avoided, invalidity due to lack of hospital facilities, tardy surgical attendance which prolongs suffering in place of speedy relief—all these things may be used to impress local sentiment deeply.

By the time a survey of this kind has been completed, it would seem that public sentiment would probably be ready to back a hospital of the type required to meet the established needs of the community.

It seems not unlikely that in many communities the diagnostic clinic and laboratory may prove a nucleus from which local hospital facilities will be developed. Such a clinic is likely to develop in physicians the spirit of cooperation, and will bring them together at a central point where, through provision of special facilities, far more accurate diagnoses can be made than are possible under ordinary circumstances. It seems but a step, even though an important one, from such a central clinic to a hospital. The hospital may then house the clinic as well as the patient who needs hospital care in accordance with the diagnosis of the clinic.

Though the hospital occupies an important place in any health program, it may be pointed out that other steps looking to health preservation may well precede it. A hospital established with public funds and maintained by the public results from organized local action. The more efficient the organization of health forces, and the more careful the planning which preceded its establishment, the more secure is the foundation of the hospital likely to be, and the more valuable its services.[11]

A hospital represents a considerable outlay of funds. Numerous important lines of health work, which as life-saving and health-improving factors may outrank hospital service, can be put under way and effectively prosecuted in a community with an expenditure far less than that required for the establishment of a community hospital.

Hospital experience seems to have shown that the full benefits of the service will not be enjoyed by a community until sentiment has ripened to an adequate appreciation of exactly what hospital service means. Through the organization of the health forces of a community, by which is meant the formal getting together of those who are appreciative of the public health movement and have come to acquire an interest in matters of personal hygiene, it will be possible to set on foot important constructive measures which are likely to accomplish distinct improvements in health conditions long before the local hospital should appear on the scene. Such movements are always worth encouraging. The personal touch thus given to work, which is likely to be constantly extended, may prove much like the snowball rolling downhill that gains in size and momentum as it courses on its way. In time—in a short time in some communities, and a longer time in others—the occasion may be ripe for the launching of the hospital project with the assurance that the institution is likely to receive the support of the community and to be utilized to its fullest extent. No aspect of the hospital movement seems more unfortunate than that of a community which has burdened itself with a hospital before the bulk of the people have become appreciative of its mission, and which as a result must struggle to get the patronage needed to maintain the institution and to enable it to render the services for which it was established.

---

[11] An interesting statement by Joseph J. Weber, at the time executive secretary, and chairman of the Committee on Hospitals, State Charities Aid Association of New York, which is intended as an argument for the organization of local health forces through the establishment of county health associations prior to the establishment of general county hospitals, appeared in *The Survey*, October 16, 1915.

New and Nonofficial Remedies

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

W. A. Puckner, Secretary.

DIPHTHERIA ANTITOXIN, CONCENTRATED (See N. N. R., 1919, p. 265).

The Gilliland Laboratories, Ambler, Pa.

Gilliland's Concentrated and Refined Diphtheria Antitoxin.—Prepared according to Banzhaf's method and preserved with 0.4 per cent. trikresol, contains less than 20 per cent. of solids. Marketed in ampules containing 1,000, 5,000 and 10,000 units each.

TETANUS ANTITOXIN, CONCENTRATED (See N. N. R., 1919, p. 266).

The Gilliland Laboratories, Ambler, Pa.

Gilliland's Concentrated and Refined Tetanus Antitoxin.—Marketed in ampules containing 1,500, 3,000 and 5,000 units each.

ANTIPNEUMOCOCCUS SERUM (See N. N. R., 1919, p. 271).

The Gilliland Laboratories, Ambler, Pa.

Antipneumococcus Serum, Type I.—Marketed in vials containing 100 Cc.; also in double ended vials containing 50 Cc. each, with a gravity injecting apparatus for intravenous injection.

VACCINE VIRUS (See N. N. R., 1919, p. 274).

The Gilliland Laboratories, Ambler, Pa.

Small-Pox Vaccine.—Marketed in sealed capillary tubes, in packages containing two tubes each.

OLD TUBERCULIN (See N. N. R., 1919, p. 277).

The Gilliland Laboratories, Ambler, Pa.

Original Tuberculin, "O. T."—Marketed in 3 Cc. vials.

BARBITAL (See N. N. R., 1919, p. 82).

The following dosage form has been accepted:

Barbital-Abbott Tablets, 5 grains.—Each tablet contains barbital-Abbott 5 grains.

PROCAINE (See N. N. R., 1919, p. 30).

The following dosage forms have been accepted:

Procaine Hypodermic Tablets, ¾ grain.—Each tablet contains procaine-Abbott 0.05 Gm. (¾ grain).

Procaine-Adrenalin Hypodermic Tablets.—Each tablet contains procaine-Abbott 0.02 Gm. (⅓ grain) and adrenalin 0.00002 Gm. (1/2500 grain).

ATREOL.—Ammonium Atreolate.—An aqueous solution containing as its principle constituents the ammonium salts of a mixture of organic acids containing nitrogen in the sulphonic radical which results from the action of sulphuric acid on certain petroleum distillates.

Actions and Uses.—Atreol is a mild antiseptic in solution or in ointment and may even destroy staphylococci with which it is brought in contact. It is applied locally for promoting the absorption of swellings and effusions in contusions following fractures, etc.

It is claimed to be useful in gynecologic and dermatologic practice.

Dosage.—Atreol may be employed in aqueous solution or with ointment bases, with lard, wool fat or petrolatum, or in suppositories with oil of theobroma. Preparations containing up to 50 per cent. may be used.

Manufactured by the Atlantic Refining Co., Philadelphia, Pa. U. S. patent Nos. 1,271,387 (July 2, 1918; expires 1935) and 1,073,548 (Sept. 16, 1913; expires 1930). U. S. trademark applied for.

When crude petroleum from any of the known American fields, except from those of Texas or California, is distilled to coke according to U. S. Patent No. 1,073,548 a "lubricating distillate" is obtained. When this distillate is freed from solid paraffin and from lighter oils, the residue is a form of crude lubricating oil. This is purified by treatment with sulphuric acid with production of two classes of sulphonic acids, one soluble in oil, the other insoluble in oil. The latter class of acids, called crude atreolic acid, is isolated according to U. S. Patent No. 1,271,387. This mixture of acids is purified and converted to ammonium salts. The solution of these ammonium salts in water, to which is added some glycerin, constitutes atreol. The mixture of acids which constitutes the basis of atreol is stated to have the following composition: carbon, 75.25; hydrogen, 7.63; sulphur, 6.20; nitrogen, 1.50; oxygen (by difference), 9.42.

Atreol is a black, syrupy liquid with a bitter, though not nauseating taste. It is completely soluble in water, almost entirely soluble in ethyl alcohol, but insoluble in chloroform. It is miscible with glycerin, lard, wool fat, and petrolatum in all proportions.

The aqueous solution of atreol (1:10) has a faintly acid reaction to blue litmus. The aqueous solution (1:10) yields a greenish black precipitate upon the addition of hydrochloric acid. This precipitate becomes tar-like on heating, and dissolves in water after the removal of any excess of hydrochloric acid and may be precipitated upon further addition of hydrochloric acid. Other acids and salts, e. g., sulphuric acid or aluminum sulphate, also precipitate a resin-like precipitate from the aqueous solution of atreol.

Boil an aqueous solution of atreol (1:10) with sodium hydroxide solution. Ammonia is evolved.

Incinerate 1 Gm. of atreol. Not more than 1 per cent. of residue remains.

Atreol loses not more than 38 per cent. of its weight when dried at 100 C.

Introduce 5 to 8 Gm. (accurately weighed) of atreol into a flask, add 100 Cc. of water and an excess of potassium hydroxide solution. Distill the mixture until no more ammonia passes over, collect the distillate in 20 Cc. of normal sulphuric acid volumetric solution, add two drops of methyl orange test solution and titrate the excess of acid with half-normal potassium hydroxide volumetric solution; the amount of normal sulphuric acid volumetric solution consumed corresponds to from 1.3 to 1.6 per cent. of ammonia (NH_3).

Place 5 to 6 Gm. (accurately weighed) of atreol into a beaker, add 50 Cc. of water and 10 Cc. of a 10 per cent. solution of albumin followed by 5 portions of 5 Cc. each of diluted hydrochloric acid, shaking after each addition. Make up the mixture to a volume of about 350 Cc. and filter through a dry filter. Heat to boiling, add 10 Cc. of a 10 per cent. barium chloride test solution and allow the mixture to stand. Filter off the precipitate of barium sulphate, wash, heat and weigh. The weight of barium sulphate obtained corresponds to less than 0.5 per cent. of ammonium sulphate.

Introduce about 1 Gm. (accurately weighed) of atreol into a Kjeldahl flask, dilute with 30 Cc. of water, add 5 Gm. of potassium chlorate followed by 30 Cc. of nitric acid and evaporate the mixture to about 5 Cc., on a bath of boiling water; add 25 Cc. of hydrochloric acid and evaporate to 5 Cc.; again add 25 Cc. of hydrochloric acid and evaporate to 5 Cc. Then add 100 Cc. of water, heat to boiling and add 10 Cc. of barium chloride test solution; allow the precipitate of barium sulphate to settle; filter, wash, heat and weigh. The weight of the barium sulphate corresponds to from 3.75 to 4.75 per cent. of total sulphur. Calculate the ammonia in the ammonium sulphate, as previously determined in atreol, and subtract the result from total ammonia as previously determined. The remainder represents the ammonia in the organic sulphonic acid group. Multiply this value by 1.88. The result represents the sulphur in the sulphonic group, or the "sulphonic sulphur" and amounts to at least 2.4 per cent. Calculate the sulphur contained in the ammonium sulphate as previously determined in atreol and subtract the result from "total sulphur" as previously determined; from this, subtract the "sulphonic" sulphur. The remainder represents the sulphur present as "organic" ("sulphid") sulphur and amounts to from 1.3 to 2.0 per cent.

Place about 5 to 8 Gm. (accurately weighed) of atreol into a 300 Cc. Kjeldahl flask and repeatedly evaporate to dryness with an excess of potassium hydroxide test solution to remove all combined ammonia. Determine the nitrogen in the residue by the Kjeldahl method. The amount of nitrogen in this residue corresponds to at least 0.75 per cent.

THE THEORIES OF MILK SECRETION

The progress of physiologic chemistry after the middle of the last century contributed indisputable proof of the untenability of the theory of milk secretion which prevailed prior to 1850. At that time it was assumed that the function of the mammary gland, as well as that of other secretory structures, involved essentially a filtering out from the blood of those substances that constitute the respective secretions. For certain components, such as the inorganic salts and water, an explanation of this sort seemed plausible. But as milk contains lactose, a sugar that is not present in the circulating fluid which perfuses the mammary gland, it became evident that the old theory of filtration must be given up.

To account for the appearance of specific products like lactose and casein in milk, when they are found nowhere else in the body, other secretory hypotheses were formulated. According to the oldest of these, the cells of the gland break loose bodily and disintegrate in the alveoli to form the milk solids. A trenchant criticism of this explanation was offered many years ago by the Breslau physiologist Heidenhain.[1] He pointed out that the actual disintegration for the milk produced by some cows in one day would require the replacing of all cells in the udder at least five times a day, a replacement of cells unprecedented in our knowledge of cell division.

Greater plausibility is attached to the theory that associates the activity of the mammary gland with a growth and subsequent detachment of the parts of the cells nearest the alveoli. Loaded with products partly in the form of granules, they are asserted to break away from the basal portions and then disintegrate to produce the milk solids. This conception of the process of the formation of milk has derived its support largely from histologic examinations of the appearance of the gland cells and structures in various stages of the lactation process.

Finally, there is a theory of milk formation which assumes that the cells secrete the materials of which milk is composed without unusual cell destruction. In other words, mammary secretion is analogous to the process for which structures like the salivary or pancreatic glands are responsible.

In an elaborate statistical study of the variation of different components of the milk, notably the fat and the solids not fat, in relation to age in a single breed of cows, Gowen[2] of the Maine Agricultural Experiment Station has disclosed deviations which cannot be reconciled with the cell disintegration hypotheses. Whereas the fat concentration of the milk is maintained throughout life, the proportion of solids not fat, which include sugar, proteins and salts, declines somewhat. Similarly the butter fat constituent increases in the evening milk, whereas the other solids do not share in this proportionate increment. This change of the ratio of fat to solids not fat can scarcely be reconciled with the cell destruction hypotheses; for it is not likely that the cell constitution should change morning and evening in the gland. Such inconsistencies, therefore, support the secretory hypothesis for milk production. Even the theory of a common antecedent for the milk solids can no longer be maintained. As Gowen concludes, the correlation of fat and of solids not fat with amount of milk and age precludes that possibility; for if such a common origin occurred, the fat and the solids not fat would necessarily be correlated to these other variables by comparable amounts. The milk components are not correlated equally with either milk quantity or with age; consequently the hypothesis of a common origin is not tenable. Surprisingly little is known about the process in the case of woman. There is no reason to assume, however, that what occurs in the lactation of cattle differs in its fundamental physiologic principles from the process of milk secretion in the human mammary glands.

NONSPECIFIC PROTEIN THERAPY

The treatment by nonspecific methods in a series of cases of influenzal pneumonia has been the subject of two recent papers.[3] These methods are a development of the work of Ichikawa, Kraus, Lüdke, Jobling and Petersen, and others on the treatment of typhoid fever and of Miller and Lusk's work on arthritis. In the original work in this field it was recognized that there were certain inherent dangers in the method and that wide application would be permissible only with the greatest caution and under careful control.

When vaccines and other toxic protein substances are injected intravenously a train of reactions takes place that includes: (*a*) a primary leukopenia, followed by a leukocytosis; (*b*) a primary lessening of the coagulability of the blood, followed after some interval by a reduction of the coagulation time; (*c*) a pronounced lymphagogue effect, the flow of lymph from the thoracic duct being increased three-fold; (*d*) a hyperistalsis of the intestinal tract, and (*e*) a marked splanchnic engorgement with a resulting lowering of the systemic blood pressure. The alteration of the coagulability of the blood, together with the vascular engorgement of the splanchnic area and the coincident increase in motility of the intestinal tract that follow the therapeutic injection, all tend to increase the possibility of intestinal hemorrhage. Protein therapy is therefore not a safe procedure in this particular disease. That we are able to terminate a certain number of cases of typhoid fever by crisis by means of such injections is of very great interest from a theoretical point of view.

In the treatment of arthritis the results seem much more satisfactory. The work of Miller and Lusk[4] has been confirmed by a number of observers, among them Culver, Cecil, Snyder, Cowie and Calhoun, and there seems little doubt that we may be able to give prompt relief and even permanent freedom from symptoms in a considerable percentage of cases of acute and subacute arthritis, especially those classed as of rheumatic origin—and this with practically no risk to the patient.

As with other new therapeutic measures, there is still some uncertainty as to the proper dosage, which is a matter of considerable importance, in order to arrive at a just estimate of the relative advantage or danger in the treatment. Typhoid vaccines have been extensively used because they are readily procured and give a prompt and sharp reaction. However, they have the disadvantage of inexactitude in the bacterial count, as well as being of varying degrees of toxicity, this latter factor depending not only on the use of different strains of bacteria in their preparation but on the age of the vaccine. Snyder,[5] as well as other workers, is of the opinion that the primary dose should be small—from five to ten million organisms—and that the dose of typhoid bacilli injected should never exceed two hundred and fifty million. While a sharp reaction on the part of the patient is apparently a desideratum, a sufficient response can usually be elicited with a relatively small dose. There is no object in subjecting the patient to the risk of the profound depression that follows occasionally in the wake of large doses. Indeed, the only serious results so far ascribed as due to this form of therapy have followed very large doses or the use of relatively large doses in moribund patients; or such unreasonable procedures as the intravenous injection of milk. It is true that milk injections were recommended by some of the German investigators, but they were always used intramuscularly.

In the treatment of pneumonia, Roberts and Cary[1] have employed a vaccine made up of 100 million of each of the following organisms per cubic centimeter: influenza bacilli, pneumococci, staphylococci and streptococci. Of this vaccine they injected intravenously first 0.5 c.c., later 1 c.c. In the series of 200 patients so treated there was no evidence of injury to the patients in any way. The mortality in this series was 9.5 per cent.; in a series of eighty-six patients not treated with vaccine the mortality was 31.2 per cent. In the untreated series 20 per cent. recovered by crisis; in the treated, 36 per cent. so recovered. Before any reliance is placed on such statistics they should be analyzed and compared carefully according to age periods as the death rate may vary at different ages. Cowie and Beaven[1] used typhoid vaccine in the treatment of their patients, and they consider the vaccine shock as indicated only in the early stages of pneumonia.

Before applying the treatment to such diseases as pneumonia it would seem that prudence would demand a thorough familiarity with the range of the reaction and the degree of toxicity of the preparation it is intended to use by first employing it in some arthritic cases. In pneumonia we must ever keep before us the vital factor of cardiac impairment and certainly we must not undertake any measure that may depress the function of the heart. In arthritis this danger is largely a negligible one and, with proper precaution, nonspecific therapy is not only without risk but indeed frequently followed by gratifying clinical improvement. Only in the light of experience gained in the manner indicated would it seem permissible for us to attempt to extend this form of therapy to more acute infections.

MALARIA CONTROL IN THE FUTURE

The discovery of the cause and mode of transmission of malaria has paved the way for eradication of the disease. A few years ago the task might have seemed almost hopeless in its magnitude and presumable cost. The experience of Gorgas and his co-workers in the Panama Canal Zone has, however, changed the prospect. It has given a new inspiration to the effort to overcome a menace to personal happiness and community spirit, and to eliminate a source of deterioration of physical and mental vigor. Few organizations or governments could aspire to cope with the malaria problem as efficiently and successfully as is likely to be done by the International Health Board of the Rockefeller Foundation, which has begun a world-wide campaign against hookworm disease.[1] With a view to stimulating more energetic measures against malaria, the board has also interested itself in the problem of malaria control. It is a sign of wisdom that before attempting to put into operation any finished antimalaria program, this unique organization of specialists has undertaken to test working methods and to evaluate, separately, a number of control measures.

[1] Report of International Health Board, Social Medicine, Medical Economics and Miscellany, J. A. M. A. **72**: 751 (March 8) 1919.

According to the latest report of the Rockefeller Foundation, all of the four measures tested in a preliminary way have exhibited some degree of success. In cooperation with the Mississippi State Department of Health, under the scientific direction of Dr. C. C. Bass of the Tulane University of Louisiana School of Medicine, an experiment was undertaken in 1916 to test the feasibility of controlling malaria in a community by sterilizing the human carriers. A program of this character might be feasible under conditions in which the extermination of mosquitoes is not regarded as practicable. The results of efforts involving more than 25,000 persons does not yet permit a final conclusion; but the indication, according to the report, is that the malaria rate in a given community can be reduced by direct attack on the malaria plasmodia in the blood of the human host.

An effort to control malaria by screening has been made with characteristic thoroughness in a community in Arkansas. A study of the parasite index among the population showed a reduction of 70 per cent. in the prevalence of infection within a year. From a practical standpoint it is helpful to learn that the average cost of screening in this community was less than $15 a house. The per capita cost was estimated at $1.75, thus giving a forceful justification to the slogan: "A yard of screen in the window is better than a yard of crape on the door." In another rural community, where prophylactic quinin was tried as the sole measure of control and was administered to all persons in the community in doses of 5 grains, morning and evening, making 10 grains a day for two successive days each week, there was likewise noteworthy success. A reduction of 60 per cent. in the parasite index was attained in a few months, the per capita cost of the work, omitting the overhead cost, being 57 cents.

Obviously the control of malaria by antimosquito measures should ultimately prove to be the most beneficent mode of attack. Unfortunately the expense involved is not infrequently greater than the communities concerned can be induced to bear. However, the experiments at Crossett and Hamburg, Ark., where the elimination of breeding places of mosquitoes by drainage and other modern antimosquito measures was undertaken, leave no doubt regarding the efficacy of this type of prophylactic work also. The demonstration of the possibility of diminishing the incidence of malaria by more than one method in a given community is a contribution of unusual value to modern preventive medicine. There is promise that where, for example, the cost of mosquito extermination is temporarily prohibitive, other, perhaps less expensive, methods of malaria control can be instituted.

RECENT OBSERVATIONS ON INFLUENZA IN GERMANY

A recent issue of the *Medical Supplement*[1] published monthly by the British War Office since January, 1918, covers the more recent articles on influenza which have appeared in Germany. It may be of interest to give a brief digest of these articles even at second hand. The influenza bacillus has not been found any more frequently than in this country, which confirms the general impression that it is not the primary cause of the disease. Thus Leichentritt[2] found it in the sputum in from 51 to 60 per cent. of influenza cases and in sputum examined for tubercle bacilli primarily, in 24 per cent. Pfeiffer,[3] the original discoverer of this bacillus, found it in the sputum in 51 per cent. of influenza cases examined. Fränkel,[4] Löwenfeld[5] and others appear to have found it in influenza sputum in a considerably larger percentage. After death the bacillus was found scattered throughout the body in eight of eleven cases studied by Fränkel, and Löwenfeld is said to have demonstrated it postmortem in the bronchial pus in 80 per cent. of cases. Pfeiffer found the bacillus also in the internal organs in some cases. Others, like Graetz,[6] were not able to find the bacillus either in the sputum during life or in the bronchi and lungs after death, except just occasionally. It should be remembered that in no case is there any mention of cultures having been made of material obtained from the throat or nasopharynx by means of swabs and that the results just mentioned refer, so far as concerns examinations during life, to cultures or smears of the sputum.

It would be desirable if more attention were given to the material secured by means of swabs because the results may give a better idea of the bacterial flora in the throat than study of the sputum.

Of all the authors whose work is considered, not a single one ventures to claim that the influenza bacillus is the cause of the disease.

Friedberger and Konitzer,[7] after a careful review of all recent German work, conclude that the epidemic was identical with that of 1890-1891; that the cause of influenza remains unknown; that as to the influenza bacillus, some German investigators have found it in a large percentage of cases, others hardly at all, but that since December, 1918, it seems to have been found more frequently while "diplostreptococci" (not described in detail), which were very frequent and were often found even in pure cultures, have become less frequent since last December. Of organisms other than the influenza bacillus, pneumococci, streptococci, and "diplostreptococci" are mentioned, but it does not appear that any of them have been studied closely. Friedberger and Konitzer made experiments on human beings by spraying, into the throat and nose, filtrates of secretions from the different parts of the respiratory tract in influenza but without any positive result. According to Reuter,[8] the most pronounced changes in acute cases of influenza were in the lower part of the larynx, in the trachea and in the main bronchi, the lining of which was red, swollen and covered with a yellow, gray deposit, underneath which were small hemorrhages. We need further careful observations before we can conclude that such lesions are the primary lesions of influenza, although it is true that the clinical symptoms indicate that such may be the case. He describes the lungs in influenzal bronchopneumonia as simulating the lungs of a hemorrhagic pulmonary edema. In some cases the peribronchial lymph nodes were so swollen that possibly bradycardia might have been caused by pressure on the vagus. This author speaks of the throat as being only slightly red and swollen, and the tonsils as unaffected. From the information furnished by this review it seems safe to conclude that up to the present time, the bacteriologic, anatomic and experimental work on influenza during the recent epidemic in Germany has yielded results of the same general nature as those obtained in this country, and that the primary causative agent of influenza still remains unknown.

THE LENGTH OF LIFE OF RED BLOOD CORPUSCLES

The question as to the usual length of life of the red blood corpuscles has come to have more than mere academic interest. Erythrocytes form an important part of every portion of blood that is transfused from one person to another. Ashby[9] has clearly pointed out that whether transfused blood corpuscles live and function for any considerable length of time or whether the beneficial results that have been observed to follow transfusion, outside the purely mechanical part of increasing the bulk of the depleted blood, are due to a stimulating effect on the hematopoietic function by the product of the broken down corpuscles is still an open question.

When red corpuscles disintegrate, they liberate the pigmentary portion of their constituent hemoglobin. This can be converted into bile by the liver and also excreted as fecal pigments. The fact that these are constantly leaving the body has furnished a reason for the belief that red cells are as constantly being destroyed. Since the number of red cells is ordinarily not decreased, the loss of hemoglobin must be made good by a regeneration of hemoglobin and new corpuscles to contain it. Formerly attempts were made to estimate the extent of destruction of the corpuscles from determinations of the daily excretion of bile pigments. That this plan is untrustworthy has been demonstrated by Hooper and Whipple,[10] according to whom the bile pigments arise, in part at least, from products which the liver has manufactured in excess of its needs for the elaboration of hemoglobin and which, not being needed, are excreted. A still different method of ascertaining how long a corpuscle continues to exist in the circulation consisted in attempting to determine the length of time during which foreign and easily recognized red corpuscles, such as the nucleated erythrocytes of birds, can be recognized in the blood after their injection into the circulation of a mammal. The fallacy of this procedure appeared as soon as modern studies in immunology demonstrated the exceptional instability of foreign cells in the blood serum.

Working at the Mayo Foundation, Ashby seems to have hit on a more promising method. This is based on the observation that it is possible in mixtures of corpuscles of different groups to separate the corpuscles practically quantitatively by treating with a serum that agglutinates the corpuscles of one kind, leaving the others unagglutinated. After a recipient has been transfused with blood of a group other than his own, specimens of his blood treated with a serum that will agglutinate his own corpuscles but not the transfused corpuscles show unagglutinated corpuscles in large numbers. These unagglutinated corpuscles which appear in the recipient's blood after such a transfusion are the transfused corpuscles, and their count is a quantitative indicator of the amount of transfused blood still present in the recipient's circulation.

From counts made on this basis on the blood of persons transfused in the Mayo Clinic, Ashby concludes that the life of the transfused corpuscle extends over thirty days or more. This is a longer lease than was allotted by the earlier estimates obtained by means of the now admittedly invalid assumptions. The conclusions have a practical bearing on transfusion practice. If there is ordinarily no immediate breakdown of the donated corpuscles, the suggestion to push the transfusions until a normal blood cell count is obtained deserves serious consideration. In the absence of disintegration products it becomes more likely that the stimulation of the bone marrow asserted to follow transfusion is the result of improved metabolic condition of bone marrow cells brought about by the increased content of circulating red cells rather than of some stimulatory effect of cellular débris. Or, as Ashby finally concludes, the beneficial results of transfusion may not be due primarily to a stimulating effect on the bone marrow, but more probably to the functioning of the red blood corpuscles.

Current Comment

CONTACT INFECTION VERSUS MILK-BORNE INFECTION IN STREPTOCOCCUS SORE THROAT

An interesting report on a hospital epidemic of streptococcus sore throat is that of Keegan which appears in this issue of the JOURNAL.[1] The evidence submitted by the writer indicates quite definitely that the epidemic in question was spread largely by contact in the hospital wards. The author emphasizes strongly the contact nature of the epidemic. Indeed, he goes so far as to express doubt regarding the nature of certain other epidemics of this disease that have been attributed to milk-borne infection. It seems hardly justifiable to regard epidemiologic evidence of this character as necessarily contradictory. If one epidemic is traced to contact, that need not hinder an investigator from accepting evidence that other epidemics are due to other modes of transmission. There is good evidence that diphtheria can be caused by contaminated milk, but such a statement by no means excludes the possibility or probability of diphtheria contact infection. In point of fact the contact epidemic of streptococcus sore throat reported by Keegan is not the first or the only evidence of cases of this sort on record. An extensive contact outbreak of streptococcus sore throat in the state of New York was reported several years ago by Winslow and Hubbard,[2] and recent editions of standard textbooks contain the statement that the disease may be spread both by milk and through contact. There is no escape from the conclusion that the evidence in favor of milk-borne transmission of this disease is quite convincing, not only in some of the instances cited by Keegan but also in a number of other well-studied outbreaks not mentioned in his article. The epidemic at Galesville, Wisconsin, described by Henika and Thompson,[3] gives a particularly clear-cut picture of a milk-borne epidemic. On the whole, although the report of Dr. Keegan's experience adds to our knowledge of the mode of transmission of streptococcus sore throat, his criticism of the epidemiologic reports of others does not seem particularly cogent. This evidence can hardly overthrow well-established facts such as the occurrence of genuine milk-borne epidemics of streptococcus sore throat.

AN AGE OF QUACKERY

A correspondent having called our attention to a freakish article appearing in a magazine of the "health fad" or "physical culture" type, it became necessary to buy a copy of this magazine. So much by way of apology. In clipping the various advertisements from this magazine for the Propaganda files, we discovered in the fifty-seven varieties of fakes, medical, quasi-medical, and otherwise, the dominant note of the magazine's advertisers: Short Cuts! Short cuts to life, liberty and the pursuit of happiness. Short cuts to health, of course, predominate. One learns that he may cure himself of almost anything from soft corns to cirrhosis of the liver by means of the various "internal baths" so plausibly presented by numerous gentlemen who wish to relieve humanity—of surplus cash. You can be made "a 100 per cent. man" by at least six different methods of physical training, each of which is unique and entirely different from its five worthless competitors. Are your eyes weak? There is a short cut cure for them! Are you deaf? There is a short cut to perfect hearing! Are you ruptured? There is a short cut hernia cure. Do you crave large busts? Presto change, you may have them. Every faddist shrewd enough to keep out of the insane asylum seems to be exploiting his particular panacea. One thing must be said for the advertising department of this magazine: it is at least consistent. It does not confine the short cut methods to the relief and cure of human ailments. Any one with a short cut—and the wherewithal to pay for exploiting it—is welcome. One is able, so the advertisers assure us, to "learn shorthand in 7 days;" to "increase your will power in one hour;" to "gain a thorough knowledge of law in your spare time;" to learn in one evening "the secret of being a convincing talker;" to learn to play the piano "in quarter the usual time at quarter the usual cost, and all by correspondence." Verily, we live in an age of quackery. And all the quacks are not in the medical profession, nor are all the nostrums in the "patent medicine" field. Economists tell us that never in the history of the country has there been so much money per capita as today. As a result, there are abroad in the land gentlemen who, figuratively speaking, wish you to invest. After looking through this magazine, it became obvious that the get-rich-quick fraternity does not confine its talents to selling oil stocks, real estate, or "mountain canaries."

THE INCIDENCE OF DISEASE CONTRASTED FOR WHITE AND COLORED TROOPS

Students of eugenics are wont to point out that "certain races of men, without consciousness of their action, have varied in the character of their choices (sex selection) in such a way as to bring about varied conditions in their races, with respect to resistance to disease, to mental capacity, and to moral quality."[1] Of these three factors, the resistance to disease is susceptible of most accurate estimation because it can be considered on the basis of statistical information regarding the morbidity rate in the case of a wide range of disorders. A peculiarly valuable instance is afforded by the comparison of white men and negroes in the United States Army. The numbers are sufficiently large to give some semblance of validity to the deductions which they permit. The white and colored troops live under equally good sanitary conditions and are examined with equal diagnostic skill. A study of the

[1] Fisher, Irving, and Fisk, E. L.: How to Live, New York, 1915, p. 323.

sort indicated has recently been reported by Lieutenant-Colonel Love and Major Davenport,[2] who have undertaken an analysis of more than half a million admissions to sick report in our army, including more than 15,000 for the colored troops. For many maladies the morbidity rate is the same in the two races. The army officers have, however, ascertained from the statistics that the colored troops are relatively less resistant to diseases of the lungs and pleura as well as to certain general diseases, like tuberculosis and smallpox; they are also much more frequently infected with venereal diseases, and suffer widespread complications of these diseases. Love and Davenport point out, on the other hand, that in general the skin, not only on the surface of the body but also that which is infolded to form the lining of the mouth and nasopharynx, is much more resistant to micro-organisms in negroes than in white men. The white skin seems to be relatively a degenerate skin in this respect. Furthermore, the nervous systems of the uninfected negroes show fewer cases of "instability" than those of white men. Thus there is far less neurasthenia, there are fewer instances of psychopathic states, and there is only half as much alcoholism in colored as in white troops. Nutritional disorders, such as diabetes, urinary calculi, and inflammations of the gallbladder, are also less common among the negroes. As Love and Davenport describe the uninfected negro, "he seems to have more stable nerves, has better eyes, and metabolizes better. Thus, in many respects the uninfected colored troops show themselves to be constitutionally better physiological machines than the white men."

THE MATERIALITY OF GERMS AND AUTOMOBILES

A recent issue of a Newark, N. J., paper reports the death of a 9 year old girl, the daughter of "Christian Scientists," who succumbed to diphtheria under "Christian Science" treatment. According to this report, the parents of the child asked her when she became ill whether she desired a doctor or wished to have "Christian Science" treatment, "and the little girl chose the latter because it was her belief." Presumably the answer to this tragedy on the part of the "Christian Scientists" generally, will be that children also die of diphtheria under medical treatment. This is the stock argument whenever a member of this cult "passes on." The point is not well taken. If this same little girl had been pinned under an overturned automobile, even her parents would not have urged their particular form of treatment to the exclusion of first removing the car from the child. It is true that prying up the car and taking the girl from under might not have saved her life; but in the present state of our knowledge, this would be the first and obvious thing to do. It is equally true that giving the child antitoxin might not have saved her life, but this, too, in the present state of our knowledge, should have been the first and obvious thing to do. Matter may be merely an error of mortal mind, but when it is ponderous enough, even "Christian Scientists" are forced to take cognizance of it, and to use material methods in dealing with it. Although the followers of Mrs. Eddy may not believe it, the Klebs-Loeffler bacillus is a material object, and while not so obvious as a brick, it is, in its own peculiar field, just as pregnant with danger to that other error of mortal mind we call the material body.

Association News

THE VICTORY MEETING

Subcommittee on Hotels of the Local Committee on Arrangements Assures Ample Hotel Accommodations

The chairman of the subcommittee on hotels for the Atlantic City session reports that at the present time the St. Charles, Haddon Hall, Chalfonte, Traymore, Brighton, Marlborough-Blenheim, Dennis, Shelburne and Chelsea are booked to their capacity for the week of the Victory Meeting—the annual session of the American Medical Association. The managements of these hotels have informed the committee that they will make reservations at a later date provided they are in position to do so. The other beach front hotels (The Journal, May 10, 1919, page 1410) are still in position to make reservations.

This announcement does not mean that there will be difficulty in caring for all who attend the Victory Meeting. Atlantic City is a city of hotels, and the large number of excellently equipped hotels on the side avenues will provide ample accommodations. All communications concerning hotels should be addressed to the Chairman of the Hotel Committee, Dr. David B. Allman, 1801 Pacific Avenue, Atlantic City, N. J.

Medical Mobilization and the War

Personnel of the Medical Department

For the week ending May 9, there were 17,560 officers in the Medical Corps, a decrease of 553 from the previous week. The Medical Reserve Corps contained 1,870 officers. The total number of medical officers discharged since the beginning of the war is 15,996.

Army Transfers Hospitals to Public Health Service

The hospitals at Camp Beauregard, La.; Camp Cody, N. M.; Camp Fremont, Calif.; Camp Hancock, Ga.; Camp J. E. Johnston, Fla.; Camp Logan, Tex.; Camp Sevier, S. C.; Camp Sheridan, Ala.; Dansville (N. Y.) General Hospital 13, and Nitrate Plant, Perryville, Md., with their equipment, buildings and land have been transferred by the War Department to the Treasury Department for the use of the Public Health Service in accordance with Act 326 of March 3.

Awards and Decorations

John S. Blackmar, Capt., M. C., U. S. Army, Norwich, Conn., on duty with the 372d Infantry, was awarded the Croix de Guerre.

> "He distinguished himself especially during the period of September 27 to October 6, 1918, when he showed the greatest zeal in the accomplishment of his duty, working day and night, under violent bombardment, and took care of over 400 wounded, many of whom were in a condition requiring the most difficult operations."

William C. Watkins, Major, M. C., U. S. Army, Oconto, Wis., awarded the Croix de Guerre, April 25.

Frank H. McGregor, Lieut., M. C., U. S. Army, Mangum, Okla., has been given the military war cross by King George V of England.

---

[2] Love, A. C., and Davenport, C. B.: A Comparison of White and Colored Troops in Respect to Incidence of Disease, Proc. Nat. Acad. Sc. 5: 58, 1919.

Isaiah Sicotte, Capt., M. C., U. S. Army, National Mine, Mich., has been awarded the Croix de Guerre.

"On the evening of 1st of November, 1918, near Mullen, Belgium, during a terrific enemy artillery bombardment, Lieutenant I. Sicotte, Medical Department 147th Infantry, fearlessly volunteered in the digging out and saving of seventeen men who had been buried in a farm house which was struck during this bombardment. The artillery action was such that the use of any number of men for this duty was absolutely impossible. By his wonderful service and devotion Lieutenant Sicotte dug these men out of the ruins and later rendered exceptional medical service.

Slightly Wounded

In a deferred report published in the *U. S. Bulletin* of May 1, it is reported that Marshall A. Welbourn, Capt., M. C., U. S. Army, Union City, Ind., has been slightly wounded.

HONORABLE DISCHARGES, MEDICAL CORPS, U. S. ARMY

Note.—In the following list, L. signifies lieutenant; C., captain; M., major; L. C., lieutenant-colonel; Col., colonel, and B. G., brigadier-general.

ORDERS TO OFFICERS OF THE MEDICAL CORPS, U. S. ARMY

Arkansas

To Fort McPherson, Ga., from Camp Lee, Lieut. E. B. BUCHANAN, Texarkana.

California

To Camp Dix, N. J., from Tobyhanna, Pa., Capt. C. B. ADAMS, Los Angeles.

To report to the commanding general, Western Department, from Fort D. A. Russell, Major J. E. McKILLOP, Huntington Beach; Lieut. R. S. CARTER, San Diego.

Colorado

To Walter Reed General Hospital, D. C., for instruction, and on completion to his proper station, from Fort Ontario, Capt. E. D. BURKHARD, Delague.

To Washington, D. C., from San Diego, Capt. F. L. DENNIS, Colorado Springs.

Connecticut

To Boston, Mass., from Camp Dix, Capt. E. F. McGOVERN, Bridgeport.

To Camp Zachary Taylor, Ky., base hospital, from Camp Dix, Lieut. J. H. T. SWEET, Jr., Hartford.

To Fort McPherson, Ga., from Camp Jackson, Capt. W. F. COLLINS, New Haven.

District of Columbia

To Army Medical School for instruction, from Camp Devens, Lieut. I. C. RIGGIN, Washington.

Georgia

To Camp Benning, Ga., from Camp Jackson, Capt. W. R. McCOY, Danielsville.

Illinois

To Camp Grant, Ill., base hospital, from Fort Riley, Capt. H. H. SHEETS, Oregon.

To Fort Dupont, Del., from Edgewood, Md., Capt. J. M. HUBER, Chicago.

To Fort McHenry, Md., from Camp Dix, Lieut. I. H. CUTLER, Chicago.

To Fort Sheridan, Ill., from Camp Dix, Capts. E. A. CHRISTOFFERSON, H. C. SCHUMM, Lieut. E. HANS, Chicago.

To Philadelphia, Pa., from Camp Dix, Capt. W. C. SWEET, Chicago.

Indiana

To Camp Dodge, Iowa, from New Cumberland, Pa., Lieut. S. M. COMPTON, Forest.

To Camp Jackson, S. C., base hospital, from Camp Sevier, Capt. O. E. FINK, Terre Haute.

To Fort Leavenworth, Kan., from Fort Benjamin Harrison, Lieut. E. B. M. CASEY, Attica.

To Fort Sheridan, Ill., from Camp Dix, Lieut. R. A. GILMORE, Michigan City.

The following orders have been revoked: *To Denver, Colo.,* from Camp Dix, Lieut. R. W. REID, Union City. *To Fort Riley,* from Camp Shelby, Capt. H. M. SHULTZ, Logansport.

Iowa

To Camp Dodge, Iowa, base hospital, from Camp Dix, Lieut. R. R. KULP, Davenport.

To Waco, Tex., Rich Field, from Fort Sill, Lieut. J. T. McBRIDE, Des Moines.

Kansas

To Fort Riley, base hospital, from Chicago, Lieut. C. H. SMITH, Pittsburg; from Fort Snelling, Capt. S. M. MYERS, Potter.

Kentucky

To Cape May, N. J., for instruction in the diagnosis and treatment of peripheral nerve injury cases, from Fort Thomas, Lieut.-Col. J. T. AYDELOTTE.

To Detroit, Mich., from Camp Dix, Lieut. H. L. PELLE, Louisville; from Charleston, Lieut. C. E. VIDT, Russell.

To Fort McPherson, Ga., from Camp Sevier, Lieut. J. T. MALONE, Jr., Louisville.

To Fort Riley, from Camp Zachary Taylor, Capt. F. M. WALKER, Louisville.

To Hoboken, N. J., from New Cumberland, Pa., Lieut. O. F. HUME, Mackville.

To Philadelphia, Pa., from Camp Dix, Capt. L. W. FRANK, Louisville.

Louisiana

To Walter Reed General Hospital, D. C., from Fort McPherson, Lieut. R. S. KEMP, New Orleans.

Maryland

To Camp A. A. Humphreys, Va., camp hospital, from Edgewood, Lieut. J. F. LUTZ, Baltimore.

To Fort McHenry, Md., from Camp Dix, Lieut. C. C. KELLY, Baltimore; from Garden City, Lieut. V. L. MAHONEY, Catonsville.

To Spartanburg, S. C., from Camp Travis, Capt. I. I. HIRSCHMAN, Baltimore.

To Walter Reed General Hospital, D. C., from Camp Dix, Lieut. I. ZADEK, Baltimore; from Roland Park, Capt. I. K. LOVETT. For instruction, and on completion *to his proper station,* from Camp Meade, Lieut. G. R. MICKLETHWAITE, Baltimore.

Massachusetts

To Army Medical School for instruction, from Camp Grant, Lieut. J. H. MURPHY, Dorchester.

To Boston, Mass., from Baltimore, Capt. J. B. AYER, Boston.

To Camp Devens, Mass., base hospital, from Plattsburg Barracks, Capt. E. S. JOHNSON, New Bedford.

To Fort Benjamin Harrison, from Camp Dix, Lieut. W. A. JILLSON, Westborough.

Michigan

To Camp Custer, Mich., from Long Island, Lieut. W. A. HYLAND, Grand Rapids.

To Chicago, Ill., from North Charleston, Capt. E. SMITH, Jr., Detroit.

To Detroit, Mich., from Camp Dix, Capt. T. B. MARSDEN, Detroit.

To Fort Riley, base hospital, from Camp Dix, Capt. C. G. WENCKE, Battle Creek.

To Walter Reed General Hospital, D. C., for instruction, and on completion to his proper station, from Detroit, Capt. T. S. MEBANE.

Minnesota

To Dover, N. J., from Camp Jackson, Capt. FAVOUR, Jr., Red Lake.

To Fort Moultrie, N. C., from Fort Oglethorpe, Capt. E. SCHONS, St. Paul.

To Fort Riley, from Camp Zachary Taylor, Lieut. F. W. WHITMORE, St. Paul.

The following order has been revoked: *To Fort Snelling, Minn.,* from Camp Dodge, Capt. F. M. MANSON, Worthington.

Missouri

To Biltmore, N. C., from Camp Upton, Capt. J. R. GREEN, Independence.

To Fort Benjamin Harrison, from Camp Dix, Capt. H. UNTERBERG, St. Louis.

To Fort Riley, from Plattsburg Barracks, Capt. H. M. LARUE, Kansas City.

To Fort Sheridan, Ill., from Camp Dix, Lieut. J. C. ROTTER, St. Louis.

To Mineola, N. Y., Hazelhurst Field, from Waco, Tex., Capt. D. APPLEBERRY, Belleview.

The following order has been revoked: *To Fort McPherson, Ga.,* from Fort Sill, Capt. T. J. LYNCH, St. Joseph.

Nebraska

To Fort Des Moines, Iowa, from Camp Dix, Major J. M. HENCH, Omaha.

To Muscle Shoals, Ala., from Camp Boyd, Lieut. C. W. PARKS, Lincoln.

New Hampshire

To Walter Reed General Hospital, D. C., for instruction, and on completion *to his proper station,* from Williamsbridge, Major J. J. POWERS, Manchester.

New Jersey

To Army Medical School, from Camp Dix, Capt. I. D. MINGOS. For instruction, from Camp Dix, Capt. K. F. KESMODEL; from Hoboken, Capt. J. R. DeVELLING.

To Camp John Wise, Tex., from Camp Kelly, Lieut. R. D. HENDERSON, Jersey City.

To Garden City, N. Y., from Camp A. A. Humphreys, Capt. H. D. McCORMICK, Kenvil.

New York

To Army Medical School for instruction, from Governor's Island, Major F. K. HERPEL.

To Camp Dodge, Iowa, base hospital, from Hoboken, Lieut.-Col. J. E. DAUGHERTY, Brooklyn.

To Colonia, N. J., from Hoboken, Capt. J. C. FISK, New York.

To Detroit, Mich., from Camp Jackson, Capt. H. A. GRIFFIN, New York.

To Fort Riley, from Chicago, Capt. A. I. LOWENTHAL, New York.

To Hoboken, N. J., from Camp Jackson, Capt. A. W. BRENNAN, Syracuse.

To Philadelphia, Pa., from Camp Dix, Major C. A. SQUIRES, Binghamton.

To report to the commanding general, Eastern Department, from Surgeon-General's Office, Col. T. W. SALMON, New York.

To Walter Reed General Hospital, D. C., from Camp Dix, Major E. T. WENTWORTH, Rochester.

To Washington, D. C., Surgeon-General's Office, from Camp Dix, Capt. J. M. FLYNN, Rochester.

To West Point, Miss., Payne Field, from Riverside, Lieut. H. M. SMITH, Olean.

The following orders have been revoked: *To Camp Dix, N. J.,* base hospital, from Pittsburgh, Capt. J. J. SINNOTT, Mount Vernon. *To Fort Benjamin Harrison,* from Walter Reed General Hospital, Lieut. J. HARKAVY, New York.

North Carolina

To Fort McPherson, Ga., from Camp Dix, Capt. T. E. WILKERSON, Raleigh.

To Washington, D. C., Surgeon-General's Office, from Camp Dix, Capt. R. S. CLINTON, Gastonia.

Ohio

To Camp Grant, Ill., base hospital, from Walter Reed General Hospital, Capt. C. L. IRELAND, Columbus.

To Camp Sherman, Ohio, base hospital, from Camp Dix, Lieut. G. F. BARNETT, Painesville.

To Fort Douglas, Utah, from Camp Sherman, Capt. W. E. RANZ, Youngstown.

To Fort Sheridan, Ill., from West Baden, Capt. A. N. WISELEY, Ada.

To New Haven, Conn., from Camp Jackson, Major A. B. SMITH, Elyria.

To Walter Reed General Hospital, D. C., from Hoboken, Capt. K. D. FIGLEY, Toledo.

Oklahoma

To Fort Oglethorpe, from Camp Dix, Capt. W. W. WOODY, Tulsa.

To Mineola, N. Y., Hazelhurst Field, from West Point, Capt. D. A. MYERS, Lawton.

The following order has been revoked: *To Camp Logan, Tex.,* Lieut. E. A. LEISURE, Fairfield.

Oregon

To Washington, D. C., Bolling Field, from Riverside, Lieut. C. W. ROBBINS, Gold Beach.

Pennsylvania

To Camp Boyd, Tex., from Muscle Shoals, Ala., Lieut. A. F. KLUTZ, Philadelphia.

To Camp Dix, N. J., base hospital, from Camp Lee, Lieut. J. G. LOGUE, Williamsport.

To Cape May, N. J., from Camp Dix, Capt. B. F. BUZBY, Philadelphia.

To Detroit, Mich., from Camp Dix, Capt. L. F. STEWART, Clearfield; Lieut. F. P. McCARTHY, Erie.

To Fort McHenry, Md., from Camp Dix, Major W. BATES, Philadelphia; from Surgeon-General's Office, Lieut.-Col. E. L. ELIASON, Philadelphia.

To Fox Hills, N. Y., from Camp Dix, Capt. E. W. COLLINS, Philadelphia.

To Lakewood, N. J., from Camp Dix, Lieut. R. L. LEVERTON, Athens.

To Mineola, N. Y., from Camp John Wise, Capt. C. H. KETTERER, Butler.

To Walter Reed General Hospital, D. C., from Fort McHenry, Lieut. F. S. CHAMBERS, Philadelphia. For instruction, and on completion *to his proper station,* from Fort McHenry, Lieut. N. A. TIMMONS, South Bethlehem.

Porto Rico

To Fort McHenry, Md., from Camp Las Casas, Capt. P. R. CASELLAS, San Juan.

Rhode Island

To Walter Reed General Hospital, D. C., from Lakewood, Lieut. H. D. CLOUGH, Providence. For instruction, and on completion *to his proper station,* from Camp Meade, Lieut. J. E. McCABE, Providence.

South Carolina

To report to the commanding general, Eastern Department, from Camp Jackson, Col. T. J. KIRKPATRICK, Jr.

Tennessee

To Fort McPherson, Ga., from Camp Lee, Capt. D. R. PICKENS, Nashville.

To Walter Reed General Hospital, D. C., for instruction, and on completion *to his proper station,* from Fort Benjamin Harrison, Lieut. H. C. LONG, Chattanooga.

Texas

To Biltmore, N. C., from Philadelphia, Major V. V. CLARK, Estelene.

To Camp Pike, Ark., base hospital, from Fort Sheridan, Lieut. F. W. CARRUTHERS, Dallas.

To Chicago, Ill., from Camp Dix, Lieut. M. O. REA, Pottsville.

To Detroit, Mich., from Camp Dix, Capt. L. E. DEVENDORF, Taft.

To Fort Sam Houston, Tex., base hospital, from Camp Dix, Lieut. J. R. WHISENANT, San Antonio.

To Mineola, N. Y., Hazelhurst Field, from San Antonio, Lieut. W. A. BLACK, Marlin.

Utah

To Fort Bayard, N. M., from Camp Dix, Major H. T. WICKERT, Huntsville.

To Hoboken, N. J., from Camp Jackson, Capt. D. K. ALLEN, Salt Lake City.

Vermont

To Walter Reed General Hospital, D. C., for instruction, and on completion *to his proper station,* from Fort McPherson, Lieut. H. F. TAYLOR, Hardwick.

Virginia

To Mineola, N. Y., Hazelhurst Field, from Arcadia, Capt. S. E. BROWN, Norfolk.

To Spartanburg, S. C., from Camp Lee, Major F. H. MILLS.

To Walter Reed General Hospital, D. C., for instruction, and on completion *to his proper station,* from Hoboken, Capt. L. N. HARRIS, Harrisonburg.

To Washington, D. C., Surgeon-General's Office, from Camp Dix, Major F. M. HODGES, Richmond.

Washington

To Fort Des Moines, Iowa, from Camp Dix, Lieut. H. T. BUCKNER, Seattle.

West Virginia

To Walter Reed General Hospital, D. C., for instruction, and on completion *to his proper station,* from Biltmore, Capt. C. R. IRVING, Hansford.

Wisconsin

To Fort Sheridan, Ill., from Fairfield, Ohio, Capt. E. G. FESTERLING, Reedsville.

Wyoming

To Fort Douglas, Utah, from Camp Dodge, Capt. J. H. HOLLAND, Evanston.

ORDERS TO OFFICERS OF THE UNITED STATES PUBLIC HEALTH SERVICE

Asst. Surg.-Gen. J. W. SCHERESCHEWSKY, proceed to Newport News, Va., and Wilmington, N. C., to inspect research work in sewage disposal.

Asst. Surg.-Gen. T. CLARK (Reserve), proceed to Perryville, Md., to inspect schools to determine whether building should be used as school or hospital.

Surg. JAMES A. NYDEGGER, deliver four lectures on quarantine and immigration at the School of Hygiene, Johns Hopkins University, Baltimore, Md., May 9, 14, 16 and 21.

Surg. JOHN McMULLEN, represent the Service at the School for County and City Officers at Louisville, Ky., May 12-15.

Passed Asst. Surg. R. C. DERIVAUX, represent the Service at the annual meeting of the Central of Georgia Railway Surgeons' Association at Macon, Ga., May 14-15.

Passed Asst. Surg. J. G. TOWNSEND, proceed to Rosedale, Kan., to attend the school for Kansas health officers to be held the week of May 12.

Asst. Surg. THOMAS PARRAN, Jr., proceed to Seneca, Md., for the purpose of giving a talk on rual sanitation on the evening of May 7.

Acting Asst. Surg. E. E. CABLE, proceed to Norfolk, Va., to consult with the Commissioner of Health in reference to the installation of clinic tables.

Acting Asst. Surg. R. E. GRAMLING, proceed to Burley, Idaho; to present the government's program for the control of venereal diseases on June 16 and 17.

Acting Asst. Surg. J. C. MONTGOMERY, proceed to Rosedale, Kan., to attend the school for Kansas health officers to be held the week of May 12.

Acting Asst. Surg. A. R. PILLSBURY, relieved at Hartford, Conn., proceed to the U. S. Public Health Service Hospital at Dansville, N. Y., for duty.

Acting Asst. Surg. FRANKLIN M. SEIBERT, proceed to Palo Alto, Calif., for duty in the U. S. Public Health Service Hospital.

Acting Asst. Surg. MELVIN J. TAYLOR, proceed to the U. S. Public Health Service Hospital at Dansville, N. Y., for duty.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ILLINOIS

New Officers.—At the annual meeting of the Shelby County Medical Society, held in Shelbyville, April 10, Dr. Edgar D. Kerr, Westervelt, was elected president; Dr. William G. Turney, Cowden, vice president, and Dr. Roy W. Johnson, Shelbyville, secretary-treasurer.

Personal.—Dr. Albert N. Mueller, health commissioner of Rock Island from 1909 to 1911, and in 1914 and 1915, has been reappointed health commissioner. —— Dr. Herbert Wheeler, for nearly forty years a practitioner of Grant Park, has disposed of his practice and retired from business.—— Dr. Frank G. Andreen has been elected president of the board of trustees of the village of Orion.——Dr. George F. Johnson has been elected mayor of East Moline.

Fort Sheridan Now Military Hospital.—Companies I and G of the Twentieth Infantry, the last of the soldiers of the line remaining at Fort Sheridan, received orders, May 5, to proceed to Fort Riley, Kan., and nothing now will remain at Fort Sheridan excepting the Base Hospital No. 28, under command of Col. William N. Bispham, and the necessary military help.——Major-Gen. Leonard Wood and his staff will reside at Fort Sheridan for the summer.

Tuberculosis Clinic.—A tuberculosis clinic was held in Princeton, May 6, under the auspices of the board of directors of the Bureau County Tuberculosis Sanatorium, acting in conjunction with the Illinois Tuberculosis Association. The program included a discussion of "The Medical Tuberculosis Program for the Progressive County," "Case History in the Diagnosis of Tuberculosis," "Essentials in the Diagnosis of the Early Tuberculosis," and "Inspection in Diagnosis in Early Tuberculosis." The discussion was followed by clinical demonstrations.

Chicago

Blunt Loses Legal Battle.—Dr. Arthur L. Blunt, after a long fight to keep from serving a term in the federal penitentiary for violation of the Harrison Narcotic Act, left for Leavenworth, Kan., May 8, to serve a sentence of two and a half years imprisonment in the federal penitentiary.

Home for Incurables Changes Name.—In recognition of the aid it received from the late Harlow N. Higginbotham, the name of the Chicago Home for Incurables is to be changed to the Higginbotham Home. Mr. Higginbotham was active in the management of the institution for thirty-eight years.

Dedication of Hospital.—At the dedication service of the new Mt. Sinai Hospital, held March 4, the principal address was made by Ignatius Bernard; a fund of $3,500 was started to purchase a roentgen-ray equipment; $1,000 was raised by the auction of door keys, and more than $1,000 was received in donations, by the selling of ward and room privileges. The building has cost about $150,000, and 100 beds are ready for immediate use.

The Speedway Hospital.—Comptroller Warrick of the treasury, ruled, May 3, that the act of Congress providing $3,000,000 for the acquisition by the U. S. Public Health Service of the Speedway Hospital project was not mandatory. Secretary Glass has under consideration a recommendation that the hospital building be purchased for $2,500,000 and the remaining $500,000 of the appropriation be spent in completing and equipping the buildings.

Personal.—Ernest E. Irons, Lieut.-Col., M. C., U. S. Army, has returned from service and resumed practice.——Albert E. McEvers, Major, M. C., U. S. Army, recently returned from overseas, was slightly injured, May 4, when the horse which he was riding, stumbled while attempting to clear a barrier for jumpers, in Lincoln Park.——Walter J. Sullivan, Capt., M. C., U. S. Army, who has been on service with the Fiftieth Division, Fifth British Army, since October, 1917, and who was wounded by a high explosive shell at Chemin des Dames, and after five months in a hospital was transferred to a hospital ship, and later to Malta, has returned from Europe.——Dr. Stephen R. Pietrowicz, James A. Britton and Max Biesenthal have been appointed by the executive committee of the Chicago Tuberculosis Institute, an advisory committee for the president and members of the board of county commissioners, in matters affecting tuberculosis hospitals.——William H. G. Logan, Col., M. C., U. S. Army, has returned from an inspection tour of European military hospitals.——Harry D. Orr, Lieut.-Col., M. C., U. S. Army, has been promoted to colonel and made division surgeon of the Thirty-Third Division.

Conference of Foreign Experts on Child Welfare.—At the invitation of President Wilson, Secretary of Labor, William B. Wilson, and Miss Julia Lathrop, head of the Children's Bureau, ten of the most distinguished foreign experts on child welfare will be present at a two-day conference at the Congress Hotel, May 19 and 20. The foreign speakers are Dr. René Sand, Belgium, professor of social and industrial medicine at the University of Brussels and advisor on medical inspection of the Ministry of Labor; Sir Arthur Newsholme, England, chief medical officer of the local government board; Mrs. Eleanor Barton of the Woman's Cooperative Guild, an organization of the wives of British wage earners which advocates the national protection of maternity and infancy; Sir Cyril Jackson, board of education, London; R. C. Davison, director of the juvenile labor exchanges of England; Dr. C. Mulon of the French War Department, who supervised creches maintained in connection with munition plants; Prof. Fabio Frassetto, Italy, professor of anthropology at the University of Bologna; Mr. Takayuki Namaye, in charge of reformatory and relief work and the protection of children for the Japanese Interior Department; Dr. Radmila Lazarevitch Milochevitch, Serbia, a leader in social service activities; Señorita María de Maeztu, Spain, in charge of child welfare work. Discussions will be held concerning (a) the economic and social basis for child welfare standards, (b) protection of the health of mothers and children, (c) child labor, and (d) children in need of special care.

INDIANA

Summoned Before Board.—The State Board of Registration and Examination has, it is said, cited Dr. George Koons to appear before it and show why his license to practice medicine in Indiana should not be revoked. It is alleged that Dr. Koons is guilty of the violation of the Indiana narcotic law and that on March 25, he was fined $25 and costs and sentenced to imprisonment in the county jail for ninety days, but that the jail sentence later was suspended.

Hospital Items.—Irene Byron Tuberculosis Hospital, Allen County, was opened to the public last month.——An appropriation of $135,000 has been made by the Madison County council for a county tuberculosis hospital, to be located one mile southwest of Pendleton, where a tract of 107 acres, including Idlewold, a summer resort, has been purchased for $35,000.——J. M. Miller, Upland, has offered the Grant County commissioners, 133 acres of land for a new county tuberculosis sanatorium.

Personal.—Dr. Edward E. Long, Shoals, has been appointed health commissioner of Martin County.——Dr. Guy W. Seaton has returned to Indianapolis after a year in Washington, D. C.——Carleton B. McCulloch, Lieut.-Col., M. C., U. S. Army, chief surgeon of Base Hospital No. 32, has been cited for bravery by the French government.——The home of Dr. John A. M. Aspy, Hope, was burned recently with a loss of $3,000.——Dr. Paul E. Bowers, state prison physician, Michigan City, who is at present on leave of absence on duty in war service at Sawtelle, Calif., has resigned.—— Dr. Lloyd A. Elliott has returned from France and resumed his duties as secretary of the health department of Elkhart. ——Dr. Clarence E. Cobb, superintendent of the Healthwin Sanatorium, South Bend, has resigned and has been succeeded by Dr. Robert C. Kirkwood, formerly chief of the medical service at the U. S. Army Sanatorium, Fort Bayard, N. M.——Dr. Adah McMahon, Lafayette, who went to France in August, 1918, to work in military hospitals, returned to the United States, April 25.

KANSAS

Welcome Returning Medical Officers.—The Reno County Medical Association, at its meeting, March 31, extended an official welcome to the members of the society who recently returned from military service.

Personal.—Dr. John R. Scott, Major, M. C., U. S. Army, has been promoted to Lieut.-Col., M. C.——Dr. Benjamin F. Williams, Lincoln, has been appointed a member of the

State Board of Control, for a term of two years, beginning July 1.——Dr. Alexander Haggart, Elgin, has been under treatment in the Swedish Hospital, Kansas City, Mo., for the removal of a lipoma located in the submaxillary space and adherent to the carotid artery.

New Officers.—At the annual meeting of the Seventh District Medical Society, held in Hutchinson, the following officers were elected: president, Dr. Boyd H. Pope, Kingman; vice presidents, Drs. John T. Scott, St. John, and John A. Dillon, Larned; secretary-treasurer, Dr. William F. Schoor, Hutchinson.——The annual meeting of the Golden Belt Medical Society was held in Junction City, April 3, and the following officers were elected: president, Dr. Alfred O'Donnell, Ellsworth; vice presidents, Drs. Benjamin Brunner, Wamego, and Clarence C. Goddard, Leavenworth, and secretary-treasurer, Dr. James D. Colt, Manhattan.

MARYLAND

Personal.—Henry J. Walton, Baltimore, Capt., M. C., U. S. Army, has been released from active service and has resumed his work as head of the roentgen-ray department at the University of Maryland Hospital.——Dr. Martin F. Sloan, superintendent of Eudowood Sanatorium, Towson, has returned to his post after a visit of several weeks at his home in San Antonio, Texas.

Evergreen, Jr., Hospital Under Red Cross Control.— U. S. Army General Hospital No. 7, Evergreen, Jr., has recently reverted from military to Red Cross control. The work of the reeducation of soldiers blinded in the war will be under the general management of Mr. L. W. Wallace, while Col. James Bordley, Baltimore, will remain at Evergreen, Jr., as director of the Red Cross Institute, with Charles F. Campbell as his assistant.

MINNESOTA

Advance Date of Meeting.—The chairman of the program committee of the Southern Minnesota Medical Association announces that conditions have arisen to make it necessary to change the day of the summer meeting to be held at Rochester, from June 30 and July 1, as originally announced, to June 23 and 24.

Personal.—Dr. Robert I. Hubert has been confirmed as chief city health officer of St. Paul, succeeding Dr. Gustav A. Renz, deceased.——Kenneth Taylor, Major, M. C., U. S. Army, St. Paul, has been promoted to the rank of Lieutenant-Colonel and placed in charge of medical work in the Balkans, Palestine and Poland, with headquarters in Paris.——Dr. Edward H. Nelson, formerly mayor of Chisholm, has been appointed health officer of the village.

MISSOURI

Personal.—Dr. E. Haydn Trowbridge has moved his school for nervous and backward children from the suburbs of Kansas City to Kansas City.

Meeting Night Changed.—The St. Louis Medical Society has voted to change its meeting night from Saturday to Tuesday, by a vote of 350 to 96.

Practitioners Fined.—Mrs. Mary Thiel of St. Louis was arrested by the Department of Registration and Education of the State of Illinois for practicing midwifery in Madison County, Ill., without a license and was fined $130.——Dr. Willis V. Smith, Kansas City, charged with prescribing narcotics without first giving addicts a physical examination, thus violating the city ordinance, is said to have been found guilty and fined $1,000, April 21. Six drug addicts were arrested with Dr. Smith, of whom one forfeited a bond of $200; one was fined $50 and sent to the workhouse and the other four were each fined $100 and paroled on condition that they remain away from the physician's office.

The Hyde Case.—After a trial lasting nearly the entire day, Judge Harris Robinson of the assignment division of the circuit court took under advisement the mandamus suit brought by Dr. B. Clark Hyde to compel the Jackson County Medical Society to rescind an order expelling him from the society. It is reported that Judge Robinson believes that the county has the right to try Dr. Hyde on the charge of writing the letter and may take such action as it may see fit, for it is entirely for the members of the medical society to decide whether or not Dr. Hyde is guilty of gross misconduct. The sole question at this time was, in his opinion, whether or not the state medical association had any right to act on an appeal from the Jackson County Medical Society and to order the expulsion of Dr. Hyde from that society.

NEW YORK

Society Bars Reporters.—At a meeting of the Albany Medical Society, April 8, it was voted to exclude all newspaper reporters from future sessions, and it was further decided that no information regarding the proceedings of the society shall be given to the public without having first been passed on by the board of censors.

State May Use Army Hospitals.—The State Hospital Commission has been instructed to inspect the U. S. Naval Hospital at Ward's Island and the army hospitals at Camp Mills and Camp Upton with a view to determining if they can be taken over by the state and used to house insane patients. At present the existing state hospitals are overcrowded to the extent of more than 6,000 patients.

Masonic Memorial Hospital.—At a meeting of the Grand Lodge of the state in New York City, recently, it was reported that a Masonic soldiers' and sailors' memorial hospital is to be built in Utica at a cost of $370,000. The institution will provide free medical care and maintenance for all service men of the order who make application and whose physical condition makes such care desirable.

Women's Medical Society Elects.—The Women's Medical Society of the State of New York at its annual meeting held in Syracuse, May 5, elected the following officers: president, Dr. Elizabeth Burr Thelberg, Poughkeepsie; vice presidents, Drs. Florence I. Staunton, Utica; Sarah J. McNutt, Ne York City, and Mathilda K. Wallin, New York City; secretary, Dr. Ethel D. Brown, New York City, and treasurer, Dr. Phoebe M. B. VanVoast, New York City.

New York City

Army Hospitals Ordered Closed.—Orders have been issued by Surg.-Gen. Merritte W. Ireland for the abandonment before June 1, of Debarkation Hospital No. 5, at the Grand Central Palace, the army hospital at the Rockefeller Institute, and the one at the Hotel Nassau, Long Beach, L. I. Emergency Hospital No. 4, which is at the Polyclinic Hospital, is also to be given up as a clearing house for men forwarded from base hospitals. About 17,000 wounded men have passed through the debarkation hospital at Grand Central Palace.

Conference on Narcotic Drugs.—A conference of the heads of various city departments was held recently at which a demand was voiced for more stringent laws covering the sale of narcotic drugs and explosives. Health Commissioner Royal S. Copeland submitted recommendations for handling the problem, calling for: (1) definition of drug addicts; (2) registration and identification of drug addicts; (3) passage of a law making it a misdemeanor for a physician to prescribe drugs for an addict without this identification card or for a druggist to honor a prescription without identification; (4) passage of a law making it a misdemeanor to sell narcotics without a prescription; (5) regulation by the State Narcotic Commission of amendments to the sanitary code on the subject.

Personal.—Col. A. Depage, Belgium, is accompanying Col. John Van Schaick, Jr., commissioner for Belgium, for the American Red Cross to this country and will deliver a number of addresses before medical societies thanking Americans for their contributions to Belgian relief.——William Darrach, Col., M. C., U. S. Army, has been appointed dean of the College of Physicians and Surgeons of Columbia University to succeed Dr. Samuel W. Lambert, whose resignation was accepted by the trustees of the university about a month ago. Colonel Darrach returned to this country in April.——Dr. Abraham Jacobi celebrated his eighty-ninth birthday on May 6. He received many friends who called to pay their respects.——Dr. William E. Studdiford has been appointed professor of obstetrics and gynecology in the College of Physicians and Surgeons to succeed Dr. Edwin Bradford Cragin.

NORTH CAROLINA

Personal.—Dr. John W. Long, Greensboro, formerly Lieut.-Col., M. C., U. S. Army, and commanding officer of Base Hospital Unit 65, A. E. F., was the orator of the day at the Memorial Day exercises in Greensboro, May 10.

Scavenger Supervision.—The supreme court in a recent decision in the case of Ratchford versus the city of Gastonia has established the validity of a city ordinance prescribing city supervision of the scavenger service and with a levy for such service against the property owners on which the surface closets are located.

Report on Venereal Disease.—The first report on venereal disease in the state as provided for by recent enactment has just been received by the state board of health. According to to the available data for the first month there were reported only 211 cases of gonorrhea; 131 of syphilis; five cases of gonorrhea and syphilis; two cases of gonorrhea and chancroid, and two cases of gonorrhea, syphilis and chancroid. Buncombe county led with forty-four cases, followed by Mecklenburg with forty-two, but Wake county, equally populous, reported only two cases of venereal disease. Better reports are expected by the board as physicians become familiar with the recent legislative enactments.

OHIO

Personal.—Dr. Frank Winders, Major, M. C., U. S. Army, Columbus, director of the medical service at Hoboken, N. J., has been promoted to Lieut.-Col., and has returned from service and will resume practice.——Dr. William H. Booth, Fremont, who underwent operation at the Toledo Hospital recently, has recovered and resumed practice.——Dr. Harry L. Rockwood, acting health commissioner of Cleveland, has received a permanent appointment as health commissioner.

Fight Against Trachoma.—A fight against trachoma is being waged in Portsmouth by state and city officials jointly. The campaign is of interest to other Ohio River cities, in many of which trachoma is believed to be prevalent. As a result of a survey which disclosed hundreds of trachoma cases among Portsmouth schoolchildren, a free clinic has been established. Schoolchildren are being examined and all found with the disease are receiving treatments. It is estimated that there are not fewer than 1,000 trachoma cases in Portsmouth, and a similar situation is believed to exist in other sections which have received heavy immigration from the mountainous southern states, where the disease has long been prevalent.

Hospital District Legislation.—Changes recently made in the laws governing tuberculosis hospitals do not forecast any change in the policy of the state toward these institutions. The hospital measures passed are: The Harter bill, permitting a county which holds membership in a tuberculosis hospital district to provide additional local facilities at its own expense for the care of tuberculosis sufferers, if the district hospital fails to provide adequate accommodations; the Crosser bill, authorizing a county in a hospital district to withdraw from membership and sell its interest to any other county in the district, if this action is approved by the state department of health, and the Gardner bill, authorizing a county in which a municipal tuberculosis hospital is located to establish a county hospital or to buy or lease the existing municipal hospital. All of these measures were drawn to fit special cases. The first two were designed to provide a means of settling difficulties between the counties in the Springfield Lake Sanatorium district, comprising Summit, Stark, Portage, Mahoning and Columbiana counties. The Gardner bill is intended to provide a means to transform the Cincinnati municipal hospital into a county institution. Under former law, no authority for the establishment of county hospitals exists and a county in which a municipal hospital exists may not enter a district organization. "The district hospital law remains unchanged in its essential details," says the state department of health, "and the policy of the department will be to continue encouraging the development of additional districts." Five district tuberculosis hospitals are in operation and two other proposed districts have effected preliminary organizations. Any group of from two to ten counties may by voluntary organization join in establishing a district. It is estimated that the state now has hospital accommodation for only one third of the tuberculosis sufferers who need hospital care.

Cincinnati

Personal.—Dr. Mark E. Bowles, district physician, has resigned.——Egbert W. Fell, Major, M. C., U. S. Army, chief of the neuropsychiatric section of the Walter Reed General Hospital, Washington, D. C., has been released from service and has been appointed resident clinical director of the Cincinnati Sanatorium, College Hill.

Health Prevention Work.—The city health department has asked an appropriation of $194,000 to be used in 1920 for the various phases of preventive disease work. The chief factors planned are special work in tuberculosis among negroes, the establishment of a new division on public health education, the reorganizing of the nursing service so as to have a separate bureau on public health nursing, and the inauguration of a new division on industrial hygiene.

New Department Established by University.—The University of Cincinnati has established in its college of medicine a department in industrial medicine and public health. Under the plans submitted, $100,000 is to be raised by the citizens' committee on finance, for the support of this department for five years. The traning which will be received in this department will make the students competent social and medical engineers and will also enable them to educate the general public as to the value of good health. The course in the new department will be started in October and will be open to graduates in medicine. A portion of the instruction will be given at the college and part at various industrial establishments along the lines now practiced in the cooperative course.

PENNSYLVANIA

Physicians Oppose Narcotic Tax Law.—Pittsburgh physicians, through the Allegheny County Medical Society, have made a protest against the recent amendment to the Harrison law, which increases the tax imposed on the members of the medical profession from $1 to $3. The resolution calls the measure "unjust discrimination against the medical profession in imposing on its members the federal support of a measure distinctly in the interest of the public," and calls for the repeal of the law.

Personal.—Dr. William W. Jones, Pittsburgh, has been commissioned captain in the Medical Corps, Pennsylvania Reserve Militia, and has been assigned to duty with the third infantry.——Dr. Nathaniel Ross, Wilkes-Barre, has been commissioned captain in the Medical Corps, Pennsylvania Reserve Militia, and assigned to duty with the second infantry.——Dr. John B. Lowman, Johnstown, was elected treasurer of the Medical Society of the State of Pennsylvania, April 30, succeeding Dr. George W. Wagoner, deceased.

Philadelphia

Personal.—Drs. Alice M. Seabrooke and Francis O. Allen addressed the graduates of the training school for nurses of the Children's Hospital, May 9, at the New Century Club.

Under-Graduates Hold Meeting.—At the twelfth annual meeting of the Under-Graduate Medical Association of the University of Pennsylvania, May 1, John H. Gibbon, Lieut.-Col., M. C., U. S. Army, professor of clinical surgery in Jefferson Medical College, delivered an address on "The Progress of Surgery During the War."

Clean-Up Campaign.—The week of May 3-10 was appointed as clean-up week and it was estimated that fully 2,600 extra loads of rubbage and materials of various kinds were carted to the dump during that week. Almost the entire city was divided into sections that the carting might be facilitated and both the director and chief of the bureau of city cleaning feel that this has been the most general and effective clean-up week the city has ever had.

Memorial Services for Health Director of Red Cross.—Memorial services for the late Jane O. Delano, former director of the department of health, American Red Cross, was held at the Academy of Music, May 7. Miss Delano died on April 15 in Base Hospital No. 10, Saveney, France. The entire first floor and part of the second was filled with hospital nurses in uniform. On the stage were men identified with the medical service and one hundred nurses returned from overseas. Dr. Edward Martin, late Colonel, and present M. R. C., state health commissioner, presided at the meeting, and addresses were made by M. M. Riddle, superintendent of the hospital training school at Newton, Mass., Brig.-Gen. William Thayer and John H. Finley, commissioner of public health in the state of New Jersey.

Record of Violent Deaths in 1918.—According to the records of the coroner's office, the year of 1918 had an unusual number of murders, suicides, accidents and accidental shootings. There was a marked decrease in industrial accidents, the coroner stated that the latter have steadily decreased since the passage of the workmen's compensation act. The following table shows the accidents for 1917 and 1918:

	1918	1917
Motor Car	223	161
Railroad	106	93
Elevator	24	16
Street car	111	81
Miscellaneous	589	882

In 1918 there were 123 homicides and 211 suicides. Inquests held during the year totaled 5,083. In October, when the influenza epidemic was at its height, 871 inquests were held, a record for the office.

TEXAS

Bills for Lepers Passed.—Two measures in behalf of the lepers of Texas were passed in the state House of Representatives. One repeals the bill appropriating $25,000 to provide for the erection of a leper colony. The other permits the use of this money to relieve victims of leprosy, the relief to be administered by the state health department.

Panhandle Physicians Meet.—The annual meeting of the Panhandle Medical Society, district No. 2, was held at Amarillo, March 18 and 19, and the following officers were elected: president, Dr. John J. Hannah, Quanah; vice presidents, Drs. James R. Wrather, Amarillo, and Francis M. Wilson, Canyon, and secretary, Dr. James J. Crume, Amarillo.

State Health Board Appointments.—The state board of health at its first quarterly session, April 29, announced the following appointments: assistant health officer, Dr. Oscar Davis, Anderson (reappointed); state registrar of vital statistics, Dr. N. V. Perker, Navasota; bacteriologist, Dr. George M. Graham, Austin (reappointed); director of the bureau of venereal diseases, Dr. Horace C. Hall, Laredo (reappointed); director of the bureau of rural sanitation, Dr. Platt W. Covington, Austin (reappointed), and Dr. Douglas Largen, San Antonio, as director of the state health survey.

Personal. — Dr. Thomas A. King, Vernon, has been appointed a member of the state board of medical examiners. ——The mayor of Dallas has appointed the following physicians as members of the municipal health board: Drs. William J. Calvert, Thomas J. Crowe, Joseph W. Bourland, Samuel M. Freedman, John W. Embree, S. L. Scothorne, J. J. Williams, Groesbeck, and Calvin R. Hannah of Dallas.—— Drs. Major H. Leach and Benjamin E. Howell have been appointed members of the negro welfare board of Dallas. ——Dr. Peter H. Scardino, formerly city health officer of Houston, and at present a medical officer on the Italian front, has declined the position formerly held by him as health officer, and tendered him by the city council to take effect on his return.——Dr. Henry B. Combs, Bastrop, has been elected health officer of Bastrop County.——Dr. Sidney J. Wilson has been placed in charge of the free clinic at Fort Worth.——Dr. Paul Gallagher, El Paso, has been elected associate editor of *Southwest Medicine*.——Dr. George H. Sandifer, Abilene, has been appointed a member of the state board of health.——Dr. James H. Ray, Denton, has been elected health officer of Denton County.

WISCONSIN

Antidrug Act Violator Punished.—Dr. John G. Barnsdale, Superior, convicted in the United States Appellate Court last summer for violation of the federal narcotic act, must serve the term of imprisonment of three years and pay the fine of $6,000 assessed against him at that time, as the Circuit Court of Appeals of Chicago, May 2, made a ruling affirming the decision of the lower court.

Personal.—Dr. Bertha V. Thomson has been appointed health commissioner of Oshkosh, succeeding Dr. James R. Bean, Philadelphia, who recently resigned from that position. ——Dr. Carroll D. Partridge, Milwaukee, assumed his duties as health officer of Wausau, May 1.——Gustavus I. Hogue, Major, M. C., U. S. Army, Milwaukee, has been promoted to Lieut.-Col., M. C., and placed in command of an eye, ear, nose and throat hospital in Paris.——Dr. Jacob M. Furstman has been legally confirmed as health commissioner of LaCrosse.——Dr. Clarence A. Baer, Milwaukee, who has been on duty with the American Red Cross in France, expects to resume practice in Milwaukee this month.

Hospital Items.—A three-story building is to be added to the present structure of St. Mary's Hospital, Sparta. New rooms, a new kitchen, laundry accommodations and a heating plant are to be added, and another elevator will be installed. The improvements will cost approximately $35,000. ——The general contract for the building of the Tri-County Tuberculosis Sanatorium near Salmo, Chequamegon Bay, has been let to an Ashland firm. The building, which is to be erected jointly by Ashland, Bayfield and Iron counties, at a cost of $80,000, will be completed this summer.——A hospital to cost $20,000 will be erected at Hartford by Miss Helen Lohr and her associate, Miss Esther Welton.——The Milwaukee branch of the American Fund for French Wounded is raising $6,000 to endow a bed in the Reconstruction Hospital to be built at Rheims, France, as a memorial to Americans.

Report on Charitable Institutions.—In the report of the conditions of the penal and charitable institutions of the state made by the legislature visiting committee to the governor, the institutions were found, as a whole, overcrowded. In many instances feebleminded were found in institutions for the deaf, blind and orphans, in the reform schools and prisons, because there is no other place to put them. An appalling increase of feebleminded with lack of facilities for their accommodation was noted, and immediate sterilization of feebleminded, male and female, in the state was recommended. The School for Dependent Children at Sparta was severely criticized. The committee reports that there seems to be a complete lack of sympathy between the executive and assistants and more than forty out of the 242 inmates are in such low mentality that they should be transferred from the institution. The Home for the Reformation of Women, near Fond du Lac, which has cost about $250,000, is said to be entirely ineffective and the committee recommends $200,000 for new and suitable buildings. At the Industrial School for Girls there was said to have been 247 inmates, 5 per cent. of whom are subnormal, and 20 per cent. of whom are afflicted with venereal disease.

CANADA

Academy of Medicine, Toronto.—At the annual meeting of the Academy of Medicine, Toronto, May 6, Dr. Edmund E. King was elected president; Dr. Jabez H. Elliott, vice president; Dr. Frederick C. Harrison, honorary secretary, and Dr. J. Herbert McConnell, treasurer. The fellowship of the academy is now 500, of whom 132 served overseas. These are now gradually returning to resume practice in Toronto.

Ontario Board of Health and Salvarsan.—Dr. John W. S. McCullough of the Ontario Board of Health states that the action of the Dominion government in refusing a permit to the provincial board to manufacture the German product is the greatest stumbling block to carrying out the Ontario Venereal Diseases Act effectively. Another application has been made to the federal authorities. Since July 1, 1918, there have been reported to the board the following cases of venereal diseases: syphilis, 853; gonorrhea, 1,586; chancroid, 40.

Personal.—Dr. Frederick J. White, Moncton, N. B., has been appointed local representative in medicine by the Soldier's Civil Reestablishment and Invalided Soldiers Commission of Canada.——Dr. Philip I. Nash, New Brunswick, has been appointed to the pension board as specialist in ear, nose and throat for the province of New Brunswick.——Dr. Joseph N. Roy, Montreal, oculist and aurist to the Hotel Dieu Hospital, has been made Laureate of the Academy of Medicine, Paris, France.——Dr. Alfred Massey, Belleville, Ont., has won distinction in the Belgian Congo, where he was medical officer over a battalion of native troops. He has been awarded the rank of major, and has been decorated with La Croix de Chevalier de l'Ordre Royal de Lion.

LATIN AMERICA

Elections in the Lima Medical Faculty.—Dr. E. Odriozola, chief of the editorial staff of the *Crónica Médica* and professor of clinical medicine, has been elected dean of the Facultad de Medicina, Dr. R. L. Flórez, sub-dean; and Dr. M. A. Velásquez, secretary.

Proposed Congress of the Latin American Medical Press.—The Cuban Medical Press Association has appointed a committee, consisting of Drs. Tamayo, Fernández and López Silvero, to start and foster a movement for a congress of the editorial staffs of the Spanish-American medical journals.

Celebration of Núñez' Fiftieth Anniversary.—The Sociedad de Estudios Clinicos of Havana recently presented Dr. E. Núñez, director of the Mercedes Hospital, with a gold medal as a tribute of esteem on the fiftieth anniversary of his entering on the practice of medicine. The presentation was made at a festival meeting presided over by the Secretario de Sanidad y Beneficencia, the chief of the public health service.

Death of Dr. Noguera of Colombia.—Dr. Oscar Noguera, one of the prominent surgeons of Bogotá, Colombia, S. A., has just died. Dr. Noguera had been educated in Germany, and was considered the pioneer in modern surgery in Colombia, having introduced a number of operations. Because of blindness he was compelled to give up the practice of surgery, acting since that time as director of public health of the District of the Atlantic.

New Journal in Cuba.—There has just appeared the first number of a new medical journal, *Revista Cubana de Oftal-*

mologia, published at Havana. The price of subscription is $6 a year. It is the intention to publish it trimestrially, although the first number covers a period of six months, containing two numbers in one volume, as is often the practice in Latin countries. This journal, as its title indicates, will be devoted exclusively to ophthalmologic subjects. The *Revista* is well printed, is illustrated, and contains 226 pages of reading matter. Its editor is Dr. F. M. Fernández and the *secretario*, Dr. J. M. Penichet.

Scarcity of Arsphenamin in Peru.—The *Reforma Medica* of Lima deplores the scarcity of arsphenamin preparations. A single dose of a French neoarsphenamin costs 10 or 12 soles, and any of the drug with a German trademark costs 40, 50 or even 80 soles. Arsphenamin of English and American makes is still unknown in Peru; and the Japanese product sells for about 30 soles, without much demand for it. The price of arsphenamin before the war was about 5 or 6 soles per dose. The consequence of this scarcity of the drug is the pathogenic rehabilitation of syphilis, the editorial declares, and implores the government to take the necessary steps to relieve this intolerable state of affairs. The sol of Peru is equivalent to a little less than 50 cents.

GENERAL

Æsculapian Society to Meet.—The Æsculapian Society of the Wabash Valley, whose membership includes eastern Illinois and western Indiana, the oldest medical society west of the Allegheny Mountains, will hold its annual meeting at Danville, Ill., May 29.

Railway Surgeons Meet.—The Association of American Railway Chief Surgeons, which met at the Commodore Hotel, New York City, May 5 and 6, elected the following officers for the ensuing year: president, Dr. Clarence W. Hopkins of Chicago; vice president, Dr. Duncan Eve, Nashville, Tenn.; secretary and treasurer, Dr. Louis J. Mitchell, Chicago.

Speech Disorder Experts to Meet.—The National Society for the Study and Prevention of Speech Disorder will hold its summer meeting in Milwaukee, July 4, as one of the affiliated societies of the National Education Association. Any one desiring to receive an advance program should address the secretary, Miss Marguerite Franklin, 110 Bay State Road, Boston.

Southern Railway Physicians Elect Officers.—At the annual meeting of the Association of Surgeons of the Southern Railway, held in New Orleans, April 24, the following officers were elected: president, Dr. Harry T. Inge, Mobile, Ala.; vice presidents, Drs. William H. Armstrong, Rogersville, Tenn.; Daniel W. Scott, McDonough, Ga.; Albert R. Wilson, Greensboro, N. C., and William T. Mathews, Greenwood, Miss., and secretary, Miss Edith Foltz, Washington, D. C. Washington was selected as the next place for the annual meeting.

Bequests and Donations.—The following bequests and donations have recently been announced:

St. Vincent's Hospital, New York City, $25,000; St. Francis' and St. Joseph's hospitals, each, $10,000, and Misericordia Hospital, New York City, $2,000, by the will of John E. Manning.

Infants Hospital, Boston, and Industrial School for Cripples and Deformed Children, Boston, each $10,000; Free Home for Consumptives, Boston, the house of testator, Brookline, together with 3,000 feet of land in memory of his son, Frederick W. Thym; Massachusetts General Hospital, $10,000, to be devoted after the death of his wife for an endowment of a free bed; and the Free Hospital for Women, Brookline; all of the residue, personal and mixed, after the payment of bequests and trust funds, by the will of George William Thym, Brookline.

FOREIGN

First Scandinavian Pediatrics Congress.—The *Ugeskrift f. Læger* announces: "The Første nordiske Kongres for Pædiatri is to convene at Copenhagen Aug. 15 and 16, immediately preceding the nordiske Kongres for intern Medicin." The subjects appointed for discussion are acute digestive disturbances with artificial feeding; the etiology, classification and treatment. The main addresses will be by Bloch of Copenhagen and Johannesson of Christiania. The secretary general is Dr. A. H. Meyer, V Boulevard 51, Copenhagen B.

The Spanish Asylum for Orphans of Physicians.—The Colegio del Principe de Asturias is approaching completion so that the candidates are being selected. It is proposed to give the preference to boys between 5 and 10 and girls from 4 to 11, and there will be accommodations for 100 in the completed portion. The asylum is to be maintained in part by stamps which are to be affixed to all medical certificates and other medical documents. Already stamps to the value of 134,881 pesetas have been taken by the fifty different provinces into which the country is divided, and orders for 39,141 pesetas worth are filed.

Invasion of China by American Brewers.—The threatened invasion of China by American brewers owing to the closing down of their business in America by the President's order has stirred the educational and missionary communities of China, and strong protests have already been forwarded to the American minister in Peking to prevent the country from being soaked with beer. The National Medical Association of China favors this condemnation of the proposed introduction of a new evil into China. The people of China have been fighting the opium and morphin dangers and do not wish to see an alcohol problem crop up just as the old ones are disappearing.

Moral Welfare Work in Shanghai.—The Shanghai Moral Welfare Committee, consisting of representatives of about eleven religious and charitable associations in Shanghai, was formed May 16, 1918, for the purpose of effecting the abolition of every form of commercialized vice in Shanghai. This committee proposes to present resolutions before the ratepayers' meetings to secure (1) deletion from the law of the word "brothel," and (2) cessation of examination of female prostitutes by municipal officers and the issuing of certificates to such examinees. It is sought to prohibit placards in streets and advertisements in newspapers of quack remedies for venereal diseases; to publish health cartoons and simple literature on the dangers of venereal disease and their prevention; to organize free treatment places for sufferers of venereal diseases; to discourage the sale of intoxicants and to establish a vice commission to deal with the matter.

Fight on Typhus.—The International Red Cross Committee at Geneva, Switzerland, acting through the American legation at Berne, has invited the United States to name representatives on a joint international commission to consider means and take measures for preventing the further spread of typhus. The cable brings reports of the alarming spread of spotted or exanthematic typhus in eastern Europe, especially in Poland, Siberia and the Ukraine. The epidemic threatens to extend over central and western Europe. The calling of an international meeting to fight the scourge, as was done in Serbia in 1915, was requested of the International Red Cross Committee by the Austrian Red Cross. The general situation affecting the matter in question is now under consideration at the Cannes conference of specialists, who are engaged in preparing reports for submission to the forthcoming international convention of Red Cross societies at Geneva.

International Scientific Relations.—In 1915 the official *Bulletin* of the French Académie de Médecine reported that the Académie had decided to drop from its list of associate members those German scientists who had signed the "Manifesto signed by the 93" upholding the military authorities in their method of conducting the war, protesting that the spirit of German science and the spirit of militarism are one, not in opposition. The Manifesto was issued as a protest against the statements in English and other papers seeking to excuse the German scientists as not upholding "Prussian militarism." When the Allied armies entered Strasbourg they found copies of a similar Manifesto, dated Oct. 16, 1914, which bore the signatures of 3,000 professors and other scientists throughout the German empire. The wording was identical with the "Manifesto of the 93." It bore the notice that it was issued by the "Kaiser Wilhelm Dank," Flottwellstrasse 3, Berlin, and was certified by Prof. D. Schaefer, Berlin-Steglitz, Friedrichsstrasse 7. In 1915, the Académie had been content to drop merely the associate members, hoping to learn that their corresponding members had published later some protest against the ruthless militarism. But, as the contrary has proved to be the case, the Académie, after study of the subject by a committee, voted, March 18, almost unanimously, to drop the corresponding members in the German countries. Consequently, the official *Bulletin* states that all connection has been severed with the following eight German scientists: Erb and Kossel of Heidelberg; Schmiedeberg of Strasbourg; Filehne and Hirschberg of Berlin; Unna of Hamburg, and Benedikt and Adamkiewicz of Vienna. The Académie also voted unanimously against taking part in international gatherings with German scientists who had signed the Manifesto.

LONDON LETTER

London, April 23, 1919.

Graduate Medical Education in London

An elaborate scheme for graduate medical education has been formed, and it is hoped will receive support from the government. Graduate teaching is required for the following classes: (1) physicians in Great Britain who would like to spend a portion of their holidays in getting up to date in all branches of their work, or who wish to spend a few months in learning all that they can about some particular subject in which they desire to specialize, either completely or in conjunction with general practice; (2) medical officers of the Royal Navy, the Royal Army Medical Corps, the Royal Air Force, and the Indian and Colonial Medical Services, who have to attend postgraduate courses at stated intervals; (3) graduates from British colonies, India and Egypt, including those who have recently qualified, and wish to complete their medical education in England, and some senior men who fall into the same category as the men in Class 1; (4) graduates of allied countries, especially Americans, large numbers of whom have in the past studied in Germany and Austria, in many instances simply because they were unable to obtain equal facilities in England, as well as the French, who have hitherto rarely studied abroad, and the Japanese.

All the existing London undergraduate medical schools have agreed to provide the following postgraduate instruction:

1. *General Courses.*—Each medical school will provide annually two courses of postgraduate teaching, each of a fortnight's duration, or one course of a month's duration, at the discretion of the individual schools, a succession of periods being arranged so that such teaching is obtainable throughout the year. The dates of the courses at each school will vary from year to year, so that more or less convenient periods will fall to different schools in different years. Each school will be asked three months in advance to draw up a program which will give opportunities for study throughout the working day in the subjects included in the courses, and will decide how many students can be admitted to each course.

2. *Special Courses.*—Special courses will be arranged in the schools, in which a graduate may have the opportunity of deeper study in any particular subject. Such courses will usually last for not less than three months, and it may be advisable that different parts of the courses should be carried on at different institutions. The special courses will be as comprehensive as possible. For example, a course in disorders of digestion might include: (*a*) lectures by an anatomist, a physiologist, a pathologist, a radiographer, a physician and a surgeon; (*b*) clinical teaching on cases in the wards and outpatient departments and on other cases collected by the teacher from his wards or outpatient departments during the previous six months; (*c*) practical instruction in the roentgen-ray investigation of disorders of digestion by the radiographer; (*d*) practical instruction in chemical analysis of gastric contents and feces by the clinical chemist; (*e*) practical instruction in bacteriologic and microscopic examinations of feces by the pathologist; (*f*) demonstrations on museum and postmortem specimens by a demonstrator of morbid anatomy or by any other physician interested in the subject; (*g*) demonstrations on the use of the sigmoidoscope; (*h*) opportunities for seeing operations on cases already investigated by the students. After having attended such a special course, a graduate may apply to the teacher for permission to do research work under him or to act as his clinical assistant. Facilities will be afforded for students to attend the ordinary hospital practice of the medical schools.

The existing London postgraduate schools and special hospitals which have given postgraduate instruction in the past will continue to do so in cooperation with the other teaching institutions working with the association. There will be no limit placed on the duration of their courses of instruction, which may continue throughout the year.

[Note.—See also p. 1484, this issue.—Ed.]

Disabled Pensioners

The problem of men disabled by the war is a big one. There are now 600,000 disabled men to whom pensions have been granted, and about 20,000 new awards are being made every week as men are demobilized or discharged from hospital. It is estimated that there will be at least 700,000 temporary pensioners, of whom an unknown number will become entitled to permanent pensions. The government has arranged to take over the orthopedic hospitals from the army and to establish outpatient clinics in surrounding towns and districts under the direction of the surgeons attached to these hospitals; similarly, treatment will be provided in hospitals and outpatient clinics for cases of nervous disease. It is hoped in this way to make a resurvey of patients who will benefit from treatment by orthopedic and nerve specialists and to give a further chance of treatment to those who have, for one reason or another, discontinued it. The number of disabled men who will require industrial training under the government scheme is about 350,000. The men who have lost a limb number 24,000, and those who have received some injury either to a leg or an arm not necessitating amputation, 128,000; it is probable that a large number of these will not be able to carry on the same manual labor as before. The neurasthenics number 36,000, and many of them will require outdoor employment, as would also many of the 60,000 suffering from chest complaints, including tuberculosis. The number of cases of rheumatism is 39,000; some have been cured, but others will require to find indoor work. Of the 54,000 men suffering from heart trouble many may have to change their previous occupation if it involves heavy physical strain. Many of the 10,000 men suffering from deafness will be unfit to go back to their previous employment. The blind who have received training will number 1,435. Of the 350,000 men, some have been cured, but a large number are still under treatment and not yet ready for training; many are capable of resuming their previous occupation, but many more have been attracted by high wages to occupations which may prove to be temporary. At present the ministry of pensions has trained, or has in training, 24,000 men. Arrangements have been made through local war pensions committees, which have 600 schemes, and instruction has been given at technical institutions, agricultural colleges, farms and market gardens. In all the main industries, trade advisory committees have been formed to advise the local committees, but new schemes and a great extension of the training facilities are required.

The Outbreak of Rabies

The occurrence of cases of rabies in the west of England has been reported in a previous letter, after an absence of the disease from this country for more than twenty years. It was stamped out by muzzling dogs in all the affected areas. The disease is supposed to have been introduced by soldiers bringing in dogs from the continent of Europe. The greatest precautions were taken and they were forbidden to do this, but it is supposed that soldiers must have smuggled in dogs to which they had become attached and that some of these dogs were diseased. The number of verified cases of rabies which has occurred in Great Britain in the outbreak is 156, of which two have occurred in the London area. So far, no case of hydrophobia is known. The compulsory muzzling of dogs with a wire cage is in force all over London and in the affected districts of the country. Any dog found at large without a muzzle will be taken to a police station. If the name and address of the owner are on the collar, he will be communicated with, and unless the animal is claimed within seven days it will be destroyed. Dogs suspected of rabies will be destroyed at once. All movement of dogs out of the scheduled areas, except for purposes of quarantine, is forbidden. Provision has been made by the government for the treatment with specific antirabic material supplied by the Pasteur Institute of Paris. The names of all persons reported as having been bitten by dogs suspected of rabies will be sent at once to the health officer.

Longevity of the Limbless

At the opening of a hospital for the limbless in London, Colonel Openshaw of the London Hospital said that a man who had lost one leg was likely to live longer than if he had not lost it, and that a man who had lost two legs would probably live longer still. It was therefore very necessary to make adequate provision for men deprived of arms or legs as the result of the war. These men were likely to live long and to require attention for many years to come. There was a physiologic reason for his statement about longevity. The heart had to carry the blood to the extremities and, other things being equal, would continue to work longer if the legs were taken away. A man who had lost both his legs could be a better swimmer than before his loss.

Compensation for Miners' Phthisis

Since the passing of a compensation act for miners' phthisis by the first Union Parliament of South Africa, 4,000 miners have benefited, and an outlay of $15,000,000 has been made. The victims in the primary stage have received $1,500 and in the secondary stage $3,750. A new bill has just been introduced increasing the $1,500 to $1,750 and substituting for the

$3,750 a payment of from $50 to $75 per month, subject to residence in the Union. Moreover, in the hope of inducing the miner to leave work underground before his working capacity is impaired, the bill proposes to grant a lump sum of $10,000 to men in what is defined as the "anteprimary stage," when there are physical signs of lung trouble short of definite silicosis.

MEXICO LETTER

Mexico City, May 4, 1919.

The Sixth National Medical Congress

There has just been issued the call for this meeting, which will be held at Toluca, April 18-26, 1920, under the presidency of Dr. J. Terrés. At the closing session of the preceding congress, invitations were received from the three cities of Toluca, Monterey and San Luis Potosi, but as the first invitation was received from the authorities of the state of Mexico, its capital, Toluca, was unanimously chosen. The committee organizing the congress, which also made the arrangements for the first congress on typhus fever, has devoted considerable time to its task, and has designated committees in all the states and territories and asked a number of physicians to discuss various subjects.

In addition to physicians, pharmacists, dentists, veterinarians, engineers and lawyers will be entitled to participation in the congress. The different sections will be: (1) anatomy, histology and physiology; (2) internal medicine (including neuropathology and psychiatry, dermatology and syphilography and medical pediatrics); medical therapeutics, pharmacology, pharmacy, and natural history (medical); (3) surgery and surgical therapeutics, including otorhinolaryngology, andrology and surgical pediatrics; (4) ophthalmology; (5) obstetrics and gynecology; (6) hygiene, medical geography, climatology, and sanitary engineering; (7) legal medicine, medical teaching and ethics; (8) military medicine and surgery; (9) dentistry; (10) veterinary science. The papers to be presented at the congress must be written in Spanish, and not consume more than twenty minutes' time, with the exception of original papers, which will be allowed twice as much time. All the papers must be in writing. Among the subjects suggested by the organizing committee are the following: arterial pressure among Mexicans; histology of the blood of the new-born and of pregnant women; the "mal del pinto"; the treatment of syphilis; the therapy of leprosy; the etiology of cancer; the geographical distribution of goiter; the treatment of glaucoma; the frequency of vertex presentation in Mexico; the use of pituitary extracts in obstetrics; gonorrhea in women; criminal abortion and its prevention; venereal prophylaxis; somatological anthropology and various applications of anthropometry; measures against the use of mariahuana (*Cannabis indica*) by soldiers; treatment of penetrating wounds of the abdomen; the treatment of pyorrhea and bovine pyroplasmosis.

The registration fee is five pesos, and members will receive a volume containing the papers presented and the discussions. All the communications about the congress should be addressed to the secretary, Dr. F. Ocaranza, 2/a Calle de S. Juan de Letrán, No. 19, Mexico City.

Mexican Red Cross

This association has received more than $2,800 as the result of a function organized last month by the ladies of the American colony, who did this to show their gratitude to the Mexican people for their generosity in patronizing the benefits held during the war to collect funds for the allied charities.

The Scarcity of Meat

Beef, which a few years ago sold at 25 cents a kilogram (about 11 cents a pound), has been rising in price until now it is $1.40 a kilogram (about 63 cents a pound). This is considered too much for a country like Mexico, which raises its own cattle, and it is believed the rise in price is due to speculations of profiteers.

The School of Medicine

The School of Medicine is planning to hold, May 5, a *Kermesse* for the purpose of obtaining funds toward the erection of a monument to the late Justo Sierra, who was the founder of the National University and secretary of public education under the government of General Diaz.—— Dr. J. Terrés, one of the oldest professors of the School of Medicine and also of the High School, has resigned his positions.

PARIS LETTER

Paris, April 24, 1919.

Military Pensions

The senate has ratified the action taken by the Chambre des Députés modifying the present military pension system. The new pension rate will be fixed by the degree of invalidism or disability as determined by the Disability Board on the basis of a percentage to be expressed in multiples of five, 100 per cent. being allowed for complete disability. In the case of a private soldier who is completely disabled, the annual pension will amount to 2,400 francs. A supplementary allowance is made to those who are badly mutilated and therefore require the services of an attendant. This allowance will amount to one quarter of their pension. Blind soldiers will receive 3,000 francs annually.

A temporary pension is given to all those who are invalided temporarily for a period not to exceed two years, but this allowance may be renewed biennially after reexamination. At the expiration of any pension period, the pension may be increased or diminished or it may stand as it was if the disability is not considered to be a permanent one; or, if it is permanent, a definite pension will be allowed. No further pension will be allowed if the disability has disappeared, or if it does not incapacitate a man to the extent of 10 per cent. of his working powers. Any pensioner whose pension is still on a temporary basis who may become afflicted by a complication or whose infirmity becomes aggravated, may, without waiting for the expiration of the biennium, ask for a revision of his case, which, then, must be made within two months. The status of the temporary pensioner must be put on a permanent basis within four years, either through the conversion of the temporary pension into a permanent pension, or by the complete withdrawal of the pension. The wounded, the sick or the infirm will have the right to ask a civilian physician to assist in making the examination on the outcome of which the pensioner's status depends.

The new pension rates (in francs), with the degree of disability expressed in multiples of twenty, are given in the accompanying table.

THE NEW PENSION SCHEDULE (IN FRANCS).

Rank in French Army	Degree of Disability					
	10%	20%	40%	60%	80%	100%
Adjudant-Chef	260	520	1,040	1,560	2.080	2,600
Adjudant	255	510	1.020	1,530	2,040	2,550
Aspirant	252	504	1,008	1,512	2,016	2.520
Sergent-Major	249	498	996	1,494	1,992	2,490
Sergent	246	492	984	1,476	1,968	2,460
Caporal	243	486	972	1,458	1,944	2.420
Soldat	240	480	960	1,440	1,920	2,400

Compulsory Notification of Tuberculosis

This question continues to occupy the mind of the medical profession and remains the subject of numerous discussions at the meetings of all medical societies. At the session of the Académie de médecine, held March 25, the discussion of Dr. F. Bezançon's report bearing on this subject was begun. Professor H. Vincent declared himself to be an advocate of this measure and stated that tuberculosis is particularly prevalent in France. In 1912 the tuberculosis mortality rate in France was 211 per 100,000 population. In England it was 137, and in Italy and Spain, 149. In 1913, 84,443 deaths from tuberculosis were registered in France. To this figure should be added the greater part of the deaths from chronic bronchitis (15,277), chronic pleurisy, emphysema, etc. Vincent is convinced that compulsory notification is the necessary first step in the fight against tuberculosis. This is also true of diphtheria, cholera and plague, for only by such notification, followed by the required prophylactic measures, can these diseases be controlled effectively. While it is true that prophylaxis must be applied to the whole social body and is inseparably linked with bacteriologic prophylaxis, the latter is, nevertheless, more important, since it is directed toward the prime cause of the disease, the bacterium, and seeks out and renders innocuous the carriers as well. Contagion stalks in the homes of the rich as well as in the meanest hovel, if the infectious agent is not destroyed. In New York City compulsory notification has lessened the number of deaths from tuberculosis by 6,000 per year for the last twenty years, even before it was possible to take proper measures against overcrowding, filth and bad sanitation. The fight against tuberculosis must be directed against the tubercle bacillus, supported by general prophylactic measures. Compulsory notification is fundamental and essential for this. The work can be carried on effectively only by securing the cooperation of all other agencies, the dispensaries, sanatoriums, hospitals and house to house visitation.

Compulsory notification has aroused the opposition of the medical profession in every country in which it has been proposed and instituted; nevertheless, these same medical opponents have invariably become the most ardent advocates of the measure when the excellent results obtained by it have become apparent. Neither in foreign countries nor in the departments of France, where the Rockefeller Commission has instituted a campaign against the tubercle bacillus, nor among the 110,000 soldiers invalided for tuberculosis during the war, has material or moral damage accrued to the tuberculous person from compulsory notification. The notification is made discreetly to a sworn medical officer; hence there has been no publicity. Antituberculosis prophylaxis does not mean periodic disinfection with elaborate apparatus of the rooms occupied by the patient; more simple measures, such as those employed in sanatoriums, suffice. The instruction of the patient can be undertaken by the doctor or by the visiting nurse.

The cost of this antituberculosis campaign, based on compulsory notification, is by no means comparable with the enormous benefits, material, moral and social, that will accrue. The present losses from idleness, disease and death due to tuberculosis vastly outweigh the prospective cost. From 1871 to 1914, during the period of peace, at least 4,000,000 of the French people died from tuberculosis. This disease is a more terrible scourge than war.

Dr. P. Reynier, on the other hand, is opposed to notification. He maintains that compulsory notification has been presented in such a beguiling manner as to arouse illusive hopes. All practicing physicians are, Reynier thinks, opposed to this measure because it threatens to do away with the *right of privileged communication to* which the French people attach so much importance, and which is an honor of the medical profession. Compulsory notification makes a pariah of the tuberculous patient. Then again, compulsory *notification, if introduced at all, should not be limited to* pulmonary tuberculosis, but should include all other forms — open surgical tuberculosis and tuberculosis in general. Another reason for the hostile attitude of physicians is the *possibility of error in* diagnosis. In case of error, will the doctor be held responsible? Reynier believes that the real remedy must be found in prophylactic measures.

The Société de pathologie comparée, however, discussed *this question and* adopted a resolution to the effect that the society is convinced of the need for a campaign against tuberculosis, but that it is not possible to take really effective measures against the disease so long as legislators *allow the* causes to continue in operation. Compulsory notification of tuberculosis cannot be accepted until alcoholism is combated in a more effective way, and so long as the *bouilleurs de cru* (private distillers, distilling the fruits they raise) are allowed to retain their special privileges. When these preliminary reforms have become operative, the society will declare itself on the question of compulsory notification of tuberculosis, for not until then can the fruits of *such discussion* have a salutary effect on the public health.

Congress on Social Hygiene

The Congrés d'hygiène sociale, summoned to consider ways and means for the reconstruction of the regions devastated by the war, held its opening session, April 22, at the Sorbonne, under the presidency of M. Henry Paté, a Paris deputy, who is also president of the Comité national de l'éducation sportive et de l'hyiène sociale. Dr. Doizy, deputy of the département des Ardennes, Medical-Inspector Sieur, Professor Pinard, and others, also took part in the proceedings. M. Paté outlined the work *in* view, stating that it would concern itself not only with the hygiene of the regions devastated by the war, but also with the hygiene of all France, various sections of the congress discussing different phases of the work. Professor Pinard emphasized the importance of the problem of depopulation and outlined the measures to be taken to obviate this very great danger.

Dr. Louis Mourier Receives the American Distinguished Service Medal

General Pershing, commander-in-chief of the American troops in France, acting for the American government, has conferred the Distinguished Service Medal on a number of persons for services rendered during the war; among those so honored being Dr. Louis Mourier, under-secretary of state for the Service de Santé militaire.

Nurse Decorated by the Legion of Honor

Mme. Herminie de Rohan, infirmière-major of the hopital V. G. 81, has been made a chevalier in the Legion of Honor, with the following citation: "For three and a half years she gave her residence for the use of the wounded and founded a surgical hospital which she herself directed. She entered the service as infirmière-major and as infirmière de salle, and without interruption, in spite of poor health, and in a splendid manner, she has always given evidence of the greatest devotion and generosity to all the wounded, wholly forgetful of herself."

Death of Dr. Charles Fernet

Dr. Charles Fernet, professor agrégé on the Paris medical faculty and honorary physician in the hospitals, is dead, aged 82 years. He was made an active member of the Académie de médecine, section on medical pathology, in 1897.

Personal

The following faculty changes have been made in the Ecole de médecine et de pharmacie at Rennes: Dr. Millardet, professor of hygiene and legal medicine, has been made professor of general pathology, internal pathology and legal medicine — a newly created chair.

Dr. Marquis, assistant professor in pathology, clinical surgery and obstetrics, has been made professor of external pathology and clinical professor of genito-urinary diseases. This is also a new chair.

Dr. Bourdinière, assistant professor of pathology and clinical medicine, is now professor of general and applied hygiene, a newly created chair.

Dr. Chevrel, assistant professor of pathology and clinical medicine is now professor of histology, succeeding the late Dr. Perrin de la Touche.

Antituberculosis Measures

The city of Paris and the département of the Seine have interested themselves in carrying out a program of constructing inexpensive homes so as to obviate the danger of contracting and spreading tuberculosis which results from overcrowding. The Office public des habitations à bon marché du département de la Seine, at the suggestion of Mr. Sellier and Mr. Dormoy, has published some maps which show the close relationship existing between overcrowding and increased mortality. This is particularly true of Aubervilliers, Saint-Quen, Gentilly, the nineteenth and twentieth arrondissements — the most populous *districts — where the* number of poorly lodged persons is the greatest and the mortality from tuberculosis the highest. Besides erecting cheap homes, the city of Paris has also purchased *ground in the* suburbs, at Champigny, Suresnes and Chatenay, which will be used for the creation of "garden cities."

Marriages

Joseph Leo McGinley, Lieut., M. C., U. S. Army, Wilkes-Barre, Pa., on duty at Camp Mills, N. Y., to Miss Alberta Crittenden Allen, of New York City, April 17.

Eric Thorston Williams Boquist, Asst. Surg., Lieut., U. S. Navy, Minneapolis, to *Miss Elizabeth* Bacon of New York City, April 30.

Karl Dean Figley, Capt. M. C., U. S. Army, Toledo, Ohio, to Miss Margaret Patterson Morgan, of Bloomfield, N. J., April 23.

William Lordan Keller, Colonel, M. C., U. S. Army, Hot Springs, Ark., to Miss Sara Irvine Greenway, at Hot Springs, April 23.

Frank A. Will, Capt., M. C., U. S. Army, Des Moines, to Mrs. Ethel Israel Will, in Kansas City, Mo., April. 29.

James Bumgardner Murphy, Major, M. C., U. S. Army, New York City, to Miss Ray Slater, of Boston, April 26.

Charles Simon Raadquist, Hibbing, Minn., to Miss Pauline Swanson, of Warren, Minn., April 23.

Omar Oakley Hall, Milford, Ill., to Mrs. Flore E. Flutro, of Paxton, Ill., at Watseka, Ill., April 22.

Fred C. James, Gadsden, Tenn., to Miss Mary Humphrey of Fruitvale, Tenn., April 23.

Jennings Sipe Lincoln, to Miss Violette H. *Fryer, both* of Baltimore, April 29.

Deaths

Nathanial Garland Keirle, Baltimore; University of Maryland, Baltimore, 1858; aged 85; a member of the Medical and Chirurgical Faculty of Maryland; since 1897 director of the Pasteur Institute of Baltimore; physician in charge of the Dispensary of the College of Physicians and Surgeons for twelve years; president of Clinical Society of Maryland from 1887 to 1888; demonstrator and professor of pathology and medical jurisprudence and later emeritus professor in these branches in the College of Physicians and Surgeons; medical examiner (coroner) for Baltimore City since 1887; died at his home, May 2.

Andrew Jackson Detwiler ⊕ Capt., M. C., U. S. Army, Hannibal, Mo.; University of Michigan, Ann Arbor, 1900; aged 45; who had been on duty at Fort Riley, Kan., and was honorably discharged from the Army, December 7, 1918; state sanitary chemist and bacteriologist of Missouri, from 1902 to 1906; died at the home of his brother in Columbia, Mo., April 22, from the effects of a gunshot wound, believed to have been self-inflicted with suicidal intent, while despondent over ill health.

Henry Edgar Bunch ⊕ Major, M. C., U. S. Army, Charleston, S. C.; Medical College of Georgia, Augusta, 1912; aged 29; who had served for two years in France with the British Army; and later rejoined the United States Forces in the Chateau Thierry and Argonne offensives; who had returned home and was awaiting demobilization in Camp Upton, sustained a fracture of the skull in an automobile accident, April 25, and died in the Camp Merritt Hospital, April 27.

Zachariah Turner Sowers ⊕ Washington, D. C.; Columbian University, Washington, D. C., 1870; Bellevue Hospital Medical College, 1871; aged 72; a veteran of the Civil War; founder and for thirty-two years president of the Washington Foundling Hospital; chairman of the board of Legislation of the District of Columbia Medical Society; a member of the visiting staff of the Garfield and Providence hospitals; died at his home, April 23.

William Frederick Hake ⊕ Grand Rapids, Mich.; University of Michigan, Ann Arbor, 1882; aged 57; a member of the staff of the Union Benevolent Association and Butterworth hospitals, for thirty years physician to St. Johns Orphanage, a specialist in diseases of children; for eleven years major and surgeon of the Second Infantry, Michigan N. G.; died at his home, April 26, from pernicious anemia.

Joseph Merzbach ⊕ Brooklyn; Long Island College Hospital, Brooklyn, 1883; aged 62; a specialist on internal medicine; instructor in gastro-enterology in the Brooklyn Post-Graduate School; attending physician to the Jewish Hospital, and chief gastro-enterologist to the Jewish Dispensary; consulting physician to the Brooklyn Hebrew Orphan Asylum; died at his home, April 28, from heart disease.

Richard Carney, Windsor, Ont.; University of Toronto, Ont., 1869; Bellevue Hospital Medical College, 1869; aged 76; medical health officer of Windsor in 1898; city physician since 1893; vice-president of the staff of the Hotel Dieu; formerly surgeon of the Twenty-first Essex Fusiliers; consulting physician to the Grand Trunk System; died at his home, April 26, from cerebral hemorrhage.

Stephen J. Young, Terre Haute, Ind.; Medical College of Ohio, Cincinnati, 1851; aged 90; major, assistant surgeon of the 48th Illinois Volunteer Infantry, and surgeon of the 79th Illinois Volunteer Infantry during the Civil War; a member of the staff of the Union Hospital, Terre Haute, for 25 years president of the Terre Haute Savings Bank; died at his home, April 26.

Willy Carl Rudolph Voight, Ann Arbor, Mich.; University of Michigan, Homeopathic Medical School, Ann Arbor, 1918; aged 36; instructor in experimental pathology in his alma mater; died April 28, from septicemia, due to an infected wound of the finger received while performing a necropsy, eight days before.

Samuel Alton Johnson ⊕ Topeka, Kan.; Kansas Medical College, Topeka, 1897; aged 59; demonstrator of anatomy and later professor of electrotherapeutics in his alma mater; a specialist in dermatology; a member of the staff of Christ Hospital, Topeka; died at his home, April 25, from influenza.

William Lee Campbell ⊕ Kansas City, Mo.; Kansas City, Mo., Medical College, 1897; aged 63; an authority on the early history of Kansas City and the Missouri Valley, and a member of the State Historical Society; died in the Willcrest Hospital, Kansas City, April 24, from nephritis.

James Albert Nowlen ⊕ Morrison, Ill.; Rush Medical College, 1875; New York University, New York City, 1883; aged 66; local surgeon of the Chicago and Northwestern Railway; county physician of Whiteside County since 1887; died at his home, February 12.

Charles S. Dwyer, Troy, Pa.; Bennett Medical College, Chicago, 1888; aged 62; while walking from Columbia Cross Roads, to Springfield, April 15, was seized with a cerebral hemorrhage, and died at Columbia Cross Roads, a few hours later.

Linus Ira Aldrich, Black Earth, Wis.; University of Iowa, Iowa City, 1888; aged 51; formerly physician of Cerro Gordo County, Iowa; a member of the State Medical Society of Wisconsin; died at his home, April 30, from heart disease.

William C. Baird, Bogard, Mo.; Rush Medical College, 1865; aged 79; a member of the Missouri State Medical Association; was thrown from an automobile, April 23, and died at his home from his injuries, the next day.

Clayton Keith, Louisiana, Mo.; Washington University, St. Louis, 1872; aged 72; secretary of the St. Louis Medical Society in 1874, and city health officer of Louisiana from 1876 to 1891; died in St. Louis, April 22.

James Saunders, Orange, Tex.; University of Michigan, Ann Arbor, 1864; aged 62; local surgeon of the Southern Pacific System; formerly acting assistant surgeon U. S. Army; died in Beaumont, Tex., April 27.

Arthur Hall Drane ⊕ Asst. Surg., Lieut., U. S. Navy, Buena Vista, Ga.; Medical College of Georgia, Augusta, 1915; aged 25; died in the City Hospital, Columbus, Ga., April 1, from tubercular peritonitis.

Gustavus Bartlett Morey, Manchester, N. H.; University of Vermont, Burlington, 1878; aged 79; a member of the New Hampshire Medical Society; died at the home of his daughter in Lawrence, Mass., April 29.

Walter Tyler Smith, Sheridan, Ore.; Willamette University, Salem, Ore., 1881; Jefferson Medical College, 1883; aged 50; a member of the Oregon State Medical Association; died at his home, April 19.

Sayer Hasbrouck, Hamilton, Bermuda, formerly of Providence, R. I.; Boston University, 1882; aged 58; a specialist on diseases of the eye, ear, nose and throat; died at his home in Hamilton, March 5.

Edward William Dean, Pittsburgh; Hahnemann Medical College, Philadelphia, 1875; aged 69; a specialist in diseases of the eye, ear, nose and throat; died at his home, April 27, from pneumonia.

William Vernon Kay, Anderson, S. C.; Medical College of Virginia, Richmond, 1916; aged 26; Lieutenant, M. C. N. G. of S. C.; died in General Hospital No. 19, Azalea, N. C., April 10.

Frederick Darwin Burton, Cleveland; Western Reserve University, Cleveland, 1879; Bellevue Hospital Medical College, 1883; aged 53; died at his home in East Cleveland, April 26.

Edward N. Pfohl ⊕ Buffalo, N. Y.; Niagara University, Buffalo, N. Y., 1888; aged 53; a member of the Buffalo Orpheus for more than twenty years; died at his home, April 15.

William Henry Seibert ⊕ Steelton, Pa.; University of Pennsylvania, Philadelphia, 1874; aged 59; a director of several banks; died at his home, April 28, from pneumonia.

Worthy A. Womble, San Antonio, Tex.; University of Tennessee, Nashville, 1891; aged 50; an advertising specialist; died in a hospital in San Antonio, April 24.

Charles E. Nusbaum ⊕ Bremen, Ind.; Northwestern University Medical School, Chicago, 1893; aged 51; died at his home, April 23, from cerebral hemorrhage.

Shepard Voorhees ⊕ Newton, N. J.; University of Pennsylvania, Philadelpha, 1888; aged 59; died April 27, from peritonitis following appendicitis.

Thomas James Nelson, Los Angeles, Cooper Medical College, San Francisco, 1903; aged 40; died in Los Angeles, April 18.

Edward Charles Bubert, Baltimore; College of Physicians and Surgeons, Baltimore, 1893; aged 52; died at his home, April 11.

Jerome Charles Street, Cohasset, Mass.; Harvard Medical School, 1853; aged 91; died at his home, March 26.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

TYREE'S ANTISEPTIC POWDER AGAIN

The "Ethical and Commercial Requirements" of the Drug Business

"I am fond of the retail drug business and follow it every day of my life. I know and observe to the fullest extent its ethical and commercial requirements." This from a circular letter recently received by physicians, and signed J. S. Tyree, who asks that he be forgiven for *writing to you personally*, but there are several reasons why he thinks the circumstances warrant it. All of which is preliminary to calling attention to an enclosure, which accompanies the circular letter, and is described as a "short memorandum" submitted for "*your consideration*."

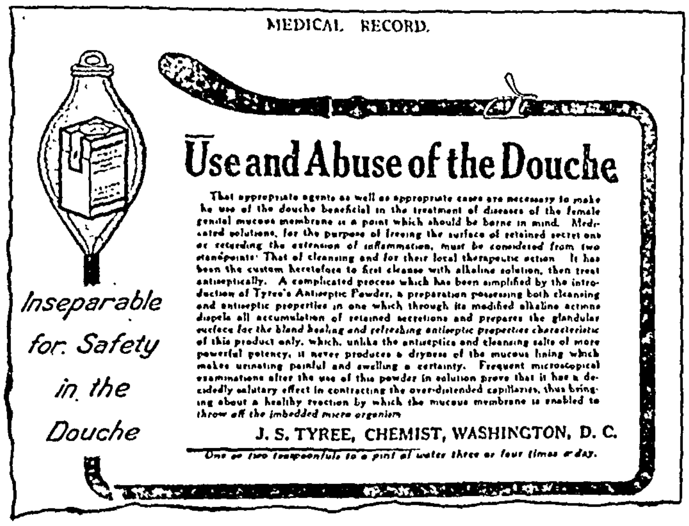
The "memorandum" is a four-page leaflet of which three pages are devoted to "Tyree's Antiseptic Powder." One of these three pages is a reproduction of a letter on the stationery of the Surgeon-General's Office of the War Department, and signed "W. M. Gray, M.D., Microscopist Army Medical Museum; Pathologist to Providence Hospital." The letter describes a series of "bacteriological and comparative tests" made by Dr. Gray with Tyree's Antiseptic Powder. The entire second page of the circular is given over to the results of these bacteriologic tests which compare various strengths of Tyree's Antiseptic Powder with "mercuric bichlorid," carbolic acid and formaldehyde.

The physicians who received this advertising material in April, 1919, might easily overlook the fact that Dr. Gray has been dead several years, that the letter which is reproduced is dated Jan. 3, 1890, and that the bacteriologic tests were made in 1889—thirty years ago!

The Council on Pharmacy and Chemistry in 1906[1] published the results of an analysis of Tyree's Antiseptic Powder which showed that although the stuff was advertised as a mixture of borax and alum, it was in fact essentially a mixture of zinc sulphate and boric acid. The publication of the Council's report in 1906, showing the falsity of the formula, brought out the admission that the composition had recently been changed. Certain it is, however, that for at least a decade past, the Tyree product has been a zinc sulphate-boric acid preparation. Yet, according to the manufacturer's own statement, Tyree's Antiseptic Powder in 1889, when Dr. Gray made his bacteriologic tests, was an entirely different substance from the present mixture.

Here then we have a manufacturer publishing in 1919, *in behalf* of a certain product, tests that were made in 1889 with a product of *different composition*, although of the same name! Is this observing "to the fullest extent" the "ethical and commercial requirements" of the "retail drug business"?

There is no scientific excuse for such a mixture as Tyree's Antiseptic Powder. If, however, physicians feel that they must use an *irrational conglomeration* such as this, why not prescribe Pulvis Antisepticus, N. F.? Like the Tyree product, this, too, is essentially a mixture of zinc sulphate and boric acid, *with minute* amounts of phenol, eucalyptol, menthol and thymol, to say nothing of a dash of salicylic acid. This official article has at least the virtue of constancy of strength, *composition* and purity assured under the federal Food and Drugs Act.



MEDICAL RECORD.

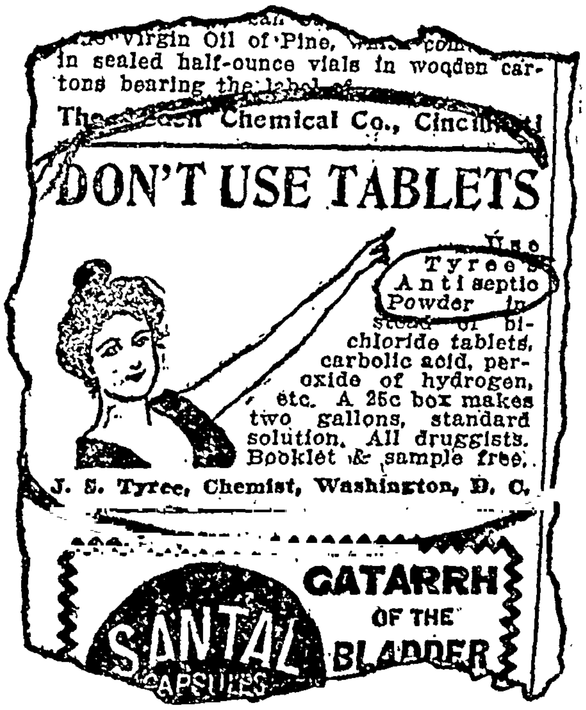
Use and Abuse of the Douche

That appropriate agents as well as appropriate cases are necessary to make he use of the douche beneficial in the treatment of diseases of the female genital mucous membrane is a point which should be borne in mind. Medicated solutions, for the purpose of freeing the surface of retained secretions or retarding the extension of inflammation, must be considered from two standpoints: That of cleansing and for their local therapeutic action. It has been the custom heretofore to first cleanse with alkaline solution, then treat antiseptically. A complicated process which has been simplified by the introduction of Tyree's Antiseptic Powder, a preparation possessing both cleansing and antiseptic properties in one which through its modified alkaline actions dispels all accumulation of retained secretions and prepares the glandular surface for the bland healing and refreshing antiseptic properties characteristic of this product only, which, unlike the antiseptics and cleansing salts of more powerful potency, it never produces a dryness of the mucous lining which makes urinating painful and swelling a certainty. Frequent microscopical examinations after the use of this powder in solution prove that it has a decidedly salutary effect in contracting the over-distended capillaries, thus bringing about a healthy reaction by which the mucous membrane is enabled to throw off the imbedded micro organism

J. S. TYREE, CHEMIST, WASHINGTON, D. C.

One or two teaspoonfuls to a pint of water three or four times a day.

Inseparable for Safety in the Douche



"Virgin Oil of Pine, ... in sealed half-ounce vials in wooden cartons bearing the label of The ... Chemical Co., Cinci...

DON'T USE TABLETS

Use Tyree's Antiseptic Powder instead of bichloride tablets, carbolic acid, peroxide of hydrogen, etc. A 25c box makes two gallons, standard solution. All druggists. Booklet & sample free.

On the right is a reduced facsimile of one of the older newspaper "patent medicine" advertisements.

Correspondence

SERVICE TO SUPPLY INSTITUTIONS WITH TEACHERS AND RESEARCH WORKERS

To the Editor:—The Federation of American Societies for Experimental Biology, comprising the sciences of physiology, biological chemistry, pharmacology and experimental pathology, is now organizing an information service to serve as a medium of communication between persons seeking positions for teaching or research and institutions that wish to fill vacancies in these sciences. Persons, whether members of the federation or not, and institutions desiring to avail themselves of the service may communicate with Prof. Edgar D. Brown, secretary of the executive committee of the federation, University of Minnesota, Minneapolis, and such information as is available will be supplied without cost to the applicant. Applicants are requested to supply the service with ten copies of their application, which should cover the following points:

1. For the person seeking a position: age; college and university training; degrees received; academic or other positions held; list of scientific papers published; membership in scientific societies; position and salary desired; copies of letters of recommendation; names and addresses of per-

---

[1] At this time Tyree's Antiseptic Powder was an "ethical proprietary"—heaven save the mark!—and advertised only to physicians. Later, as The Journal has shown, it entered the "patent medicine" field as "ideal for douche" and the "best preventative known." The articles on this nostrum are reprinted in the ninth edition of "The Propaganda for Reform."

sons who can supply further information regarding the applicant; and any other information that the applicant desires to submit.

2. For the institution desiring to fill a vacancy: title of vacant position; date to be filled; requirements as to teaching or other routine work and research; salary to be paid; prospect of tenure of office and advancement; and any other information that the institution desires to submit.

The service does not undertake to recommend or to pass judgment on applicants. It aims merely to serve as a clearing-house for such information as the foregoing and to bring into touch with one another candidates for positions and vacancies to be filled.

E. D. BROWN, Secretary.

University of Minnesota, Minneapolis.

THE PREHISTORY OF THE CADUCEUS

To the Editor:—In the discussion of the caduceus as a medical emblem (THE JOURNAL, April 26, p. 1243), your commentator states that "whoever recommended its use as a medical emblem in this country has either been conducted by Mercury, his titular deity, to join the souls of the dead in the world below, or is keeping unusually quiet." In regard to this pronouncement, I have made inquiry of Col. John Van R. Hoff, M. C., U. S. Army (ret.), until recently editor of the *Military Surgeon,* and largely responsible for the introduction of the caduceus as part of the insignia on the medical officer's uniform, and have learned from him that it was introduced in 1902 as a badge of neutrality, appropriate to the medical officer as a noncombatant. This point, emphasized in Colonel McCulloch's article in the *Military Surgeon,* is one which your correspondent has overlooked, namely, that "merchants on their trading expeditions, the success of which depended on peaceful negotiations, naturally carried their emblem, the wand of Mercury, and hence it became generally established as the badge of the nonfighting man." In itself, this was better symbolism than the Maltese cross with scalloped edges which appeared on the uniforms of our medical officers prior to 1902. The Romans had a special functionary, the *caduceator,* who was a sort of peace commissioner. Long before Churchill, the London medical publisher, had employed it (1844), the caduceus had been used on the title pages of books published by the famous medical printer Frobenius (1460-1527). It was, in fact, his personal device. As the caduceus took its place in medical heraldry about this time (crest of Sir William Butts), there must have been excellent reasons for using it as a medical symbol, known to the authorities of the period even if not yet discovered. But the caduceus as a mythological symbol goes much farther back than the culture of Hellas, as has been shown in Frothingham's important investigations (*Am. J. Archaeol.,* 1916), of which I propose to give an account in the *Military Surgeon* for June, 1919. If any one will examine the Babylonian caduceus (on a vase in the Louvre) in W. H. Ward's "Seal Cylinders of Western Asia" (1910, p. 129), he will see the starting point of Frothingham's investigation, which goes back to 3500-4000 B. C. For a number of reasons, principally as typifying the mysterious and changeable aspects of life itself, the serpent was always the symbol of medicine in antiquity. The Babylonian caduceus, which also occurs in ancient Hittite remains, stands for an actual serpent god, Ningishzida, who as the special messenger of Ishtar was the awakener of life in the springtime and the Mesopotamian prototype of the Greek Hermes. To the *Freudianer,* both snake and caduceus are libido symbols, i. e., in Jung's definition of the term, symbols of potential energy. To primitive man, the snake undoubtedly seemed the outward and visible sign of those potential energies which are summed up in the phrase, "making medicine." In other words, as Rivers has so admirably shown in his Fitzpatrick Lectures (*Lancet,* 1916), medicine, in prehistoric and primitive civilizations, was and is only one phase of a set of magic, mystic and ritualistic processes which express naught else than the savage's groping and grasping for power. Not to apprehend this is to overlook one of the fundamental postulates of medical folklore. In considering Greek mythology and medicine, it is well to remember that each divinity of the Olympian Pantheon had both a celestial and an infernal (chthonian) aspect, and so could promote health or inflict disease at will. Thus, in Arcadia, Lemnos and Samothrace, Hermes, an ithyphallic deity, was worshipped as the god of fertility in crops, men and cattle (the very essence of "making medicine") and so had undoubted medical functions, if we mean by "medicine" here the power of the gods to inflict and abort disease, which summarizes pre-Hippocratic pathology. It is worth while to note that practically all that we know of Greek medicine in the pre-Hippocratic period has been investigated and developed, not by physicians or medical historians, but by experts in archeology and philology. These researches are little known to the medical profession, and are of comparatively recent date.

The following problems seem worthy of investigation by medical historians:

1. How did the caduceus come to be introduced as a medical symbol (Johann Froben, Sir William Butts) in the early sixteenth century?

2. How did the English medical publisher Churchill come to use it about 1844?

3. How did it come to be employed on the chevrons of hospital stewards of the U. S. Army in 1856?

4. How did the well known and current French periodical of military medicine come to be called *Le Caducée* in 1901?

F. H. GARRISON, M.D., Washington, D. C.
Lieutenant-Colonel, U. S. Army.

TREATMENT OF MALARIA

To the Editor:—Kindly allow me to direct your attention to a point in an editorial on malaria containing a statement which might lead to many failures in the treatment. In THE JOURNAL for Feb. 22, 1919, the paragraph beginning on the ninth line, page 572, is as follows:

> When quinin is given continuously for three days, as just suggested, it should be stopped for about a week and then repeated.

The foregoing should read:

> When quinin is given continuously for three days, as just suggested, it should be stopped for six days and then repeated.

It has been found that after the seventh day of interruption of the use of quinin, spore-bearing plasmodia were sometimes present in cases in which quinin had been given every two hours night and day for two or three full days; this shows that some of the spores which were latent have completed their full cycle, and are again ready to produce spores at the end of this time; consequently, in these cases malaria will not be cured, because some spores of this crop may again become latent and produce further spore-bearing plasmodia later, while if the quinin is given before they have reached the spore-bearing period, namely, before the eighth day, this does not occur. This fact we have demonstrated in many hundreds of cases. For this reason the time of interruption should be definitely stated as six days instead of about one week.

A. J. OCHSNER, M.D., Chicago.

HEALTH INSURANCE

To the Editor:—In THE JOURNAL, May 10, under "Medical News," New York, is an item, "Reconstruction Committee Favors Health Insurance." This committee is a political body appointed by Governor Smith who is the first governor of New York to advocate health insurance from the executive mansion. This reconstruction committee made up its findings after hearing leading "civic workers and insurance authorities." No mention, however, is made in this issue of THE JOURNAL of the fact that the Medical Society of the State of New York, a much more competent body, instructed its delegates to the American Medical Association Meeting in 1919, to oppose in every way the project for compulsory health insurance.

JOHN P. DAVIN, M.D., New York.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

DILUTIONS OF ALCOHOL—CALORY VALUES OF SUGARS

To the Editor:—1. Andrews in his book on "Typhoid Fever" states that in case of collapse whisky should be given, one-half ounce every hour. As we cannot obtain whisky, we shall have to substitute grain alcohol. How much alcohol should be used to equal one-half ounce of whisky? 2. What is meant by whisky 100 per cent. proof? 3. What is meant by alcohol 50 per cent. by volume, or by wine containing 15 per cent. alcohol? 4. How many calories are there in a teaspoonful of milk sugar; how many in a teaspoonful of granulated sugar?

Joseph Hatton, M.D., Sarasota, Fla.

Answer.—1. Two fluidrams of alcohol, U. S. P., diluted with an equal volume of water will be the essential equivalent of one-half fluid ounce of whisky. 2. One hundred per cent. proof means equal volumes of absolute alcohol and water, i. e., 50 per cent. alcohol. When a liquor is 100 per cent. proof, it will burn. 3. Fifty per cent. alcohol by volume means that the solution is composed of equal volumes of alcohol and water. As alcohol weighs less than an equal volume of water, the percentage of alcohol by volume is numerically greater than the percentage by weight. When wine contains 15 per cent. alcohol, it is composed approximately of one volume of alcohol plus five volumes of water (which, in turn, contains some solid substances in solution, and flavors). 4. Granulated sugar yields 1,860 calories per pound: a teaspoonful, approximately from 15 to 20 calories; milk sugar about the same.

FORMULA FOR "PEPTENZYME"

To the Editor:—Will you inform me whether "Peptenzyme" has been passed on by the Council on Pharmacy and Chemistry of the American Medical Association and accepted for use by our members? If not, will you give me the formula?

X. Y. Z., Overbrook, Pa.

Answer.—Peptenzyme was reported on by the Council on Pharmacy and Chemistry along with a number of other products of Reed and Carnrick (The Journal A. M. A., Oct. 5, 1907, pp. 1198-1203). The report, "Reed and Carnrick's Methods," announced that none of the products examined were eligible for New and Nonofficial Remedies. ;The following is an abstract of the report concerning Peptenzyme:

> Pepenzyme elixir and powder are said to contain "the enzymes and ferments of all the glands which bear any relation to digestion;" therefore, the peptic glands, pancreas, salivary glands, spleen and intestinal glands. The preparations are said to be "not chemical extracts, but pure physiologic products." Apparently Peptenzyme powder consists of the glands, dried and powdered, while the elixir is an extract. It is stated that these preparations digest proteids, starch and fat, and in addition stimulate and nourish the digestive glands, and that the ferments in these preparations do not interfere with or digest one another. Examination by the Council showed that these preparations were practically devoid of any power to digest proteids or fat when tested by the U. S. P. method. The claim that the product contained ferments which would not show this activity in the test tube, but become active in the alimentary canal, is contrary to known facts and could not be substantiated by the manufacturer. The claims made for Peptenzyme powder and elixir were held to be unwarranted.

In view of the Council's report and the growing appreciation of the medical profession that mixtures of ferments are absurd, it is to be hoped that Peptenzyme has not been "accepted for use by our members."

BLOTTER INDICATING HUMIDITY

To the Editor:—I have an advertisement blotter that changes color with the changes of the weather. It is surprisingly accurate. In fair weather it is blue; in changeable weather, violet; and when it rains, pink. What chemical produces this effect?

Alfred Hultner, M.D., Belle Plaine, Kan.

Answer.—The blotter is probably impregnated with a solution of cobalt chlorid or cobalt sulphate. Cobalt salts are blue when anhydrous and pink when they contain water of crystallization or when they are dissolved in water.

Wisconsin: Milwaukee, June 24-26. Sec., Dr. J. M. Dodd, 220 E. 2nd. St., Ashland.

GRADUATE MEDICAL EDUCATION IN LONDON

A scheme for the improvement of postgraduate medical education in London was approved recently at a meeting of representatives of the various postgraduate medical schools and special hospitals. This scheme, as published in the current number of the *British Medical Journal*, is reproduced herewith. It may furnish suggestions of value in the much needed organization of graduate medical education in the large cities in this country.

A SCHEME FOR POSTGRADUATE MEDICAL EDUCATION APPROVED BY THE LONDON MEDICAL SCHOOLS

I. INTRODUCTION

A. A postgraduate association is required in order to meet the large demand for teaching from the following classes of medical graduates:

1. General practitioners in Great Britain who would like to spend a portion of their holidays in getting up to date in all branches of their work, or who wish to spend a few months in learning all that they can about some particular subject in which they desire to specialize, either completely or in conjunction with general practice.

2. Medical officers of the Royal Navy, the Royal Army Medical Corps, the Royal Air Force, and the Indian and Colonial Medical Services, who have to attend postgraduate courses at stated intervals.

3. Graduates from British colonies, India, and Egypt, including those who have recently qualified and wish to complete their medical education in England, and some senior men who fall into the same category as the men in Class I, but who are prepared to devote a longer time to the purpose than English practitioners.

4. Graduates of allied countries, especially Americans, large numbers of whom have in the past studied in Germany and Austria, in many instances simply because they were unable to obtain equal facilities in England, as well as the French, who have hitherto rarely studied abroad, and the Japanese.

B. Hitherto postgraduate teaching in Great Britain has not been encouraged in the medical schools, because the majority have considered that their first duty was to teach their own undergraduate students, and have therefore given very limited facilities to graduates.

C. It should now be recognized that, although the teaching of undergraduate students must not be allowed to suffer, the claims of graduates should also be considered, in order to promote the efficiency of the medical profession throughout the British Empire.

D. The cooperation of America and France should be secured. This could best be done through the recently organized American Postgraduate Union and the Committee of the Société Médicale des Hôpitaux de Paris on "Medical Education in the Hospitals for Foreigners."

II. SCHEME FOR GENERAL AND SPECIAL POST-GRADUATE COURSES

(a) *In the Existing London Undergraduate Medical Schools*

All of these schools have agreed to provide the following postgraduate instruction:

1. *General Courses.*—Each medical school will provide annually two courses of postgraduate teaching each of a fortnight's duration or one course of a month's duration at the discretion of the individual schools, a succession of periods being arranged so that such teaching is obtainable throughout the year. The dates of the courses at each school will vary from year to year, so that more or less convenient periods will fall to different schools in different years. The rota should be drawn up in such a way that each school may know the dates for its courses for the next three years.

Each school, after inquiring from its teachers what instruction or courses they are prepared to give, will be asked three months in advance to draw up a programme which will give opportunities for study throughout the working day in the subjects included in the courses, and will decide how many students can be admitted to each course.

2. *Special Courses.*—Special courses will be arranged in the schools where a graduate may have the opportunity of deeper study in any particular subject. Such courses will usually last for not less than three months, and it may be advisable that different parts of the courses should be carried on at different institutions. The special courses should be as comprehensive as possible. For example, a course in "disorders of digestion" might include:

(1) Lectures by an anatomist, a physiologist, pathologist, radiographer, physician and surgeon.
(2) Clinical teaching on cases in the wards and out-patient departments and on other cases collected by the teacher from his wards or out-patient departments during the previous six months.
(3) Practical instruction in the x-ray investigation of disorders of digestion by the radiographer.
(4) Practical instruction in chemical analysis of gastric contents and feces by the clinical chemist.
(5) Practical instruction in bacteriological and microscopical examinations of feces by the pathologist.
(6) Demonstrations on museum and postmortem specimens by a demonstrator of morbid anatomy or any other physician interested in the subject.
(7) Demonstrations on the use of the sigmoidoscope.
(8) Opportunities for seeing operations on cases already investigated by the students.

3. *Research Work and Clinical Assistantships.*—After having attended such a special course, a graduate may apply to the teacher responsible for the courses for permission to do research work under him or to act as his clinical assistant for a further period. For example, a graduate interested in children's diseases or orthopedics, after attending a course on one of these subjects could then, if he is regarded as sufficiently qualified, stay on at the hospital as clinical assistant and do research work under the physician for children's diseases or orthopedic surgeon respectively. At the same time he could spend an hour or two each day in following the courses given on these subjects during successive fortnights at the different schools and special hospitals. He would thus get quite exceptional opportunities for study.

4. *General Hospital Practice.*—Facilities will be afforded for students to attend the ordinary hospital practice of the medical schools.

(b) *In the Existing London Postgraduate Schools and Special Hospitals*

Those which have given postgraduate instruction in the past will continue to do so in cooperation with the other teaching institutions working with the association. There will be no limit placed on the duration of their courses of instruction, which may continue throughout the year.

(c) *Provincial, Scottish, and Irish Schools*

The medical schools of the United Kingdom will be invited to cooperate with the London Association in providing periodic courses of instruction for graduates, which would run concurrently with those of the former, especially at times, such as the summer months, when the number of graduates would probably exceed the number who could be adequately dealt with in London.

(*d*) The British Association of Radiology and Physiotherapy has agreed to cooperate.

(*e*) It is hoped that arrangements may be made to utilize for teaching purposes the unique collections of the Royal College of Surgeons and the clinical facilities of metropolitan asylums, fever hospitals, and Poor Law infirmaries, and opportunities should be given for the study of public health and forensic medicine.

III. THE CENTRAL ORGANIZATION

1. The Council of the association will consist of representatives of all participating teaching institutions, and representatives of the Board of Education, the National Health Insurance (Medical Research Committee), the Dominions, and United States of America. The number of representatives of the twelve London schools serving on the Council shall not be less than the total number of representatives of the other bodies. Care should be taken to arrange for representation of subjects taught as well as of institutions.

2. Steps will be taken to frame such a constitution for the association as will render it competent to hold property and to receive a grant from the Board of Education.

3. The Council of the association will have power to appoint an executive committee and such other administrative committees as may be necessary. The permanent whole-time officers and secretarial staff of the association will be appointed by the executive committee.

4. The home of the association will be a building in central London. It will contain the offices of the permanent (secretarial) staff, together with a library, recreation room, and luncheon and tea rooms. A suitable and well equipped building would become the meeting place for the medical graduates of the empire and allied nations.

5. The permanent secretarial staff of the association will cooperate with the teaching institutions in organizing the courses of instruction, and will issue the necessary advertisements, receive the fees, and arrange for the admission of students to the different courses in conformity with the number of students for which each is open.

IV. FINANCE

1. The participating schools will be under no financial liability in connection with the scheme.

2. It is hoped that sufficient money will be forthcoming from private donations to provide for the erection and equipment of the building and some endowment towards its annual maintenance.

3. Each student on admission will be required to pay a registration fee, which will go towards the support of the association, apart from the fees payable for the courses of instruction. It is proposed to apply to the Board of Education for a grant sufficient to make the association selfsupporting.

4. As any grant from the Board of Education will be paid to the association, the medical schools will not receive any direct government grant for postgraduate education, and will therefore only be responsible to the association for the instruction they undertake to give.

5. The fees payable for the various courses will be decided by the Executive Committee in consultation with the individual schools, the object being to maintain as nearly as possible a uniform standard.

6. Each participating school will undertake to give no organized postgraduate courses independently of the central organization, with the exception of classes for special examinations.

7. The income of the association would thus be derived from:

(1) Interest for endowment fund,
(2) Registration fees paid by students,
(3) Fees for courses, and
(4) Government grants;

and the expenditure would be for:

(1) Maintenance of the association's buildings,
(2) Salaries of permanent secretarial staff,
(3) Advertising, printing prospectuses of courses, etc., and
(5) Payment of participating schools.

V. THE POSITION OF THE UNDERGRADUATE STUDENTS IN RELATION TO THE POSTGRADUATE ASSOCIATION

In arranging the courses of instruction care will be taken to interfere as little as possible with the work of the undergraduate students. In the case of lectures no difficulty would arise from the presence of undergraduate students in seats not reserved for the postgraduates, but admission to all other forms of instruction will be restricted to those for whom the course has been arranged.

Book Notices

A STEREOSCOPIC ATLAS OF PLASTIC SURGERY OF THE FACE, HEAD, AND NECK WITH CASE REPORTS. By Joseph C. Beck, M.D., F.A.C.S., and Ira Frank, M.D., F.A.C.S. Price, $7. Pp. 131, with 90 stereoscopic illustrations. St. Louis: C. V. Mosby Co., 1919.

This stereoscopic outfit has been neatly prepared. It includes a compact stereoscope, a textbook and some ninety stereoscopic illustrations demonstrating the various steps in the technic of the operations devised by these two authors. In the text a brief introduction is followed by a historical summary of the subject, carrying the reader from the time of Tagliacozzi through the rhinoplasty with paraffin, first used by Gesurney of Vienna, down through the recent work of Roe and Lexer. The chapters include work on the palate, the eyelids, the elementary principles of plastic surgery, a new method of using silver wire and a series of quite instructive case reports chiefly devoted to injuries of the nose. The stereoscopic illustrations include nasal defects, total loss of the nose, resection of the jaw, defects of the lip and cheek, restoration of the jaw, reconstruction of the ear, tracheotomy, laryngectomy, etc. On the back of each stereoscopic view is printed a descriptive legend. It is, of course, not presumed that a study of this material will qualify the reader as a plastic surgeon. This involves a delicacy of technic to be acquired only through practice and experiment. The war produced many face wounds, and the future will demand more men qualified to do this work. The physician who desires to become conversant with the subject will find this outfit of assistance in his study of it.

The Pathology of the Pneumonia in the United States Army Camps During the Winter of 1917-1918. By William G. MacCallum, M.D. Monograph No. 10 of the Rockefeller Institute for Medical Research. Paper. Price, $1.50. Pp. 147, with 55 illustrations. New York: The Rockefeller Institute for Medical Research, 1919.

Dr. MacCallum was a member of two commissions appointed by the Surgeon-General of the Army to study the pneumonia existing among troops during 1917-1918. The pneumonia referred to was particularly that following measles. The pamphlet does not cover the severe and fatal bronchopneumonia following the influenza epidemic, except for a short supplementary note. Preliminary reports as to the findings of these commissions have appeared in articles by Dr. MacCallum and others published from time to time in The Journal. The present volume goes into the matter in considerable detail and supplements it with fifty-three excellent plates illustrating microscopic and macroscopic pathology of the disease.

Social Medicine, Medical Economics and Miscellany

Health Reorganization in England

The readjustment of social machinery to the new conditions following the war, and the agitation for better governmental control of health conditions, have stimulated a discussion in England of social insurance and governmental health organization equal to the discussion that greeted the Lloyd George social insurance bill in 1910. Not only medical journals, but also popular magazines, such as the London *Graphic,* are discussing the proposed state medical service from almost every possible point of view. The *British Medical Journal* for March 8, 1919, contains a lengthy article on "National Medical Treatment," by Dr. William J. Howarth, medical officer of health of the city of London, and Dr. B. A. Richmond, secretary of the London Panel Committee on National Medical Treatment. The editorial pages contain two editorials on the subject, and two out of the five letters in the correspondence department are also given to its discussion. In the article by Drs. Howarth and Richmond, the question is discussed largely from an administrative standpoint. In view of the prominent position occupied by health matters and the social reforms contemplated by the new government, the authors consider it desirable that the medical profession should either have some definite views as to what future action will prove acceptable to it, or be prepared to submit a scheme approved by the majority of the profession for the consideration of the general public. Evidently the ten years' discussion of this question in England has not advanced the medical profession of that country very much farther than is the case with our profession here. Three methods of altering or enlarging the present method of state insurance in England are suggested: (1) additional powers and responsibilities added to the present panel system; (2) the creation of a whole time service, and (3) the establishment of a part time service based on experience gained in panel work. The limitation of medical benefit to insured persons alone cannot continue, in the judgment of the writers. The insurance act accepts no responsibility for the treatment of persons with physical defects at ages prior to the insurance age. The treatment of the uninsured and of those requiring permanent medical treatment and maintenance, many of whom are now under the care of the poor law authorities, would still remain a problem for solution. If insured persons and their dependents were included in a state scheme of medical treatment, it is estimated that the number remaining outside such a scheme would be between one third and one fourth of the total population. This would leave from two thirds to three fourths to be cared for under the government plan. The various administrative difficulties involved would be of such magnitude, in the opinion of the writers, as to make it sound policy to open the state service to every member of the community who desired to avail himself of it. As the prosperity of the state depends on the health of its citizens, it seems reasonable to expect the state to make the provisions necessary for maintaining health by making medical treatment available for everybody, the cost to be met by different members of the community according to their taxable value. If this principle be accepted, it follows that the best medical treatment should be available for every individual. To effect this, all medical services must be coordinated. The question of the control of the proposed health organization at once arises. Drs. Howarth and Richmond suggest that it devolves on the proposed ministry of health, through the creation of central authority delegating executive power to local bodies created for this purpose or adding these powers to local bodies already existing, while the administration of benefits paid should be under the control of the contributors or their elective representatives. As medical benefits would be paid for by the whole community, the administration would devolve on elected representatives of the community, aided by elected representatives of the profession and elected representatives of those insured.

The scheme outlined by the writers to meet the conditions involves minimum essentials for the public, the profession and the local authorities. Those for the public are: (1) the best possible medical treatment available for each individual, including consultations, surgical, dental and hospital treatment, midwifery service and efficient nursing; (2) the freest choice of medical attendants consistent with administrative efficiency. As affecting the physician, the minimum essentials are: (1) the national service to be open and appointments so arranged that the slacker may be eliminated and ample opportunities afforded the beginner; (2) opportunity for competition; (3) limitation of nonprofessional work to the minimum; (4) control of physicians by the profession; (5) encouragement to physicians to improve their knowledge and to bring the general practitioner into close contact with the specialist, thereby creating better *esprit de corps;* (6) satisfactory remuneration; (7) provision for pensions on a contributory basis.

It is interesting at this point to compare these minimum essentials for physicians with the minimum essentials provided for in the resolutions adopted by the House of Delegates of the American Medical Association at the New York session in 1917. These are: (1) free choice of physicians by the insured; (2) payment to be proportionate to the amount of work done; (3) separation of official supervision from professional treatment of the sick; (4) adequate representation of the medical profession on administrative bodies.

The minimum essentials for local authorities are that: (1) The service shall be sufficiently flexible and elastic for further developments; (2) the sickness rates and knowledge gained be so recorded as to be available for local health officers.

Regarding the method of operation, the writers suggest the establishment of central clinics in areas of varying sizes dependent on the population and social status. One clinic might be required for every twenty or fifty thousand population, each clinic to be provided with attending physicians and nurses, clerks to take care of records, etc., and dispensing pharmacists to fill prescriptions. In larger areas, special clinics for special work would be provided, drawing their patients from a series of primary clinics. The details of attendance and care under various conditions are outlined at length.

General hospitals are suggested as necessary to care for those requiring hospital treatment. Naturally a single general hospital would care for the patients from a large number of primary clinics. Minor and major clinics and general hospitals would, of course, each be provided with such bacteriologic, chemical and diagnostic laboratories, equipment and trained workers as would be necessary. Consultants would be attached to the various hospitals and would carry on both private practice in home consultations and state work in hospital consultations on a basis of payment for state work to be determined by conditions. In places unprovided with hospitals, a small institution suitable for the needs of the district would be established, and in rural districts a modified organization suited to the needs of the community would be developed. In sparsely settled districts, the minor clinics would be replaced by the individual physician and the major clinics and consultation work by traveling clinics. Special operative work and hospital treatment as well as the treatment of emergency cases requiring the care, beyond the ability or resources of the local physician, would be provided for at the nearest general hospital.

Regarding expenses, a tentative estimate is made, admitting present sources of information to be limited. In any district, the fund available would be equal to the total population multiplied by the agreed capitation fee. Physicians would be paid in proportion to the number of units of treatment credited to each during any prescribed period, monthly, quarterly or otherwise. It is estimated that the cost of 27,906 hospital beds in London and the provinces is £2,855,236 (approximately $14,000,000) and that there are at least 45,000 beds provided for in private hospitals at a total cost of £4,500,000 (approximately $22,000,000). In addition there are in public institutions for contagious diseases, insane and feebleminded and the care of the poor, 264,000 beds which are already being paid for by the community, the transfer of which to a new authority would not involve any additional expense. Assuming the population of England and Wales to be 36,500,000, a charge of 13s. ($3.25) per head per annum would amount to £23,725,000 (approximately $118,750,000). Deducting the £4,500,000 for the maintenance of 45,000 hospital beds and £10,000,000 for remuneration of physicians would leave between £9,000,000 and £10,000,000 (from $45,000,000 to $50,000,000) for all the remaining work which would have to be done under the proposed plan.

Several fallacies suggest themselves in considering this estimate. The physician at present is a private practitioner. If he does much work of a high class, he is well remunerated. If he does little work or poor work, his compensation is small. If, however, medical practice is going to be so reorganized as to require each man to do a definite amount of work each day and to come up to a definite standard in his work, the average compensation as it now exists would probably be neither adequate nor fair. Furthermore, if the entire population were given the care which they should have, present hospital accommodations would not be sufficient, since many patients who today need and should have hospital treatment are now deprived of it. There would undoubtedly be considerable saving under such a scheme, as much of the sickness now existing would be prevented and ultimately this would afford a decided margin of saving; but for the first five or ten years at least under the operation of the plan, this saving would not be apparent.

The last section of the article is devoted to pensions for physicians. The plan proposed is that each physician shall contribute to a pension fund an amount based on his salary and annually deducted therefrom, depending on the age of the practitioner at the time he entered the service and varying from 2 to 3.5 per cent. of his annual salary. Optional retirement would be fixed at 60 and compulsory retirement at 65, the amount of pension depending on the length of service, forty years' service entitling the retired physician to two-thirds income.

In the correspondence department in the same issue of the *British Medical Journal* appears a letter from Lieut.-Col. Henry Smith of the Indian Medical Service, protesting against the proposed plan for the "Germanization of the British Medical profession." Government services, he claims, are fit only for third class men, "the stamp of man with little brains and as little character." His communication is mainly a criticism of the internal workings of government services.

The situation in England is essentially different from that in this country because of the following facts:

1. In England the question is a national one; in this country it is a state question.

2. England has already established and in operation a compulsory health insurance plan which includes all employed persons receiving $800 a year or less; this country has not.

3. Social, economic and professional conditions in England differ widely from those in this country.

4. In England the discussion of a proposed ministry of health, analogous to the agitation in this country for a national department of health, alters the situation as it exists in this country, since the two questions are being widely discussed at the same time and various plans proposed for their mutual solution by a single plan.

The bill for the establishment of a national ministry of health is now before Parliament, and its progress will be followed with much interest by physicians in this country.

Medicolegal

Evidence of Employment and Basis for Charges

(*Succession of Levitan et ux.* (*La.*), *79 So. R. 829*)

The Supreme Court of Louisiana, in rendering a decision in favor of the claim of a physician, holds that the testimony of a physician and surgeon, to the effect that he was employed by the mother of his patient, a married woman, rather than by the patient or her husband, and rendered valuable services, for which he considered the mother able to pay, but doubted the ability of the husband so to do, is strongly corroborated by the circumstances that the patient, having succeeded as sole heir to the estate of her mother, hears the testimony, and does not take the stand to question its verity.

It is a matter of common information that physicians and surgeons do not regulate their charges for professional services by any fixed standard of pecuniary value, but, to a certain extent, on the basis of the ability of the patient to pay, and, on that basis, more frequently than otherwise, perhaps, are but poorly compensated. Where such services are shown to have been of the highest value, so far as the life and welfare of the patient were concerned, and the charge is neither unreasonable nor inconsiderate, as compared with the financial ability of the employer, it should be allowed by the court.

The physician in this case rendered professional services to a Mrs. Gordon, daughter of Mrs. Levitan, from about May 27, 1914, until November or December of that year, during which period he successfully performed a cesarean operation on her. There was no issue here as to the value of the services or the necessity of the operation, so far as the life and well-being of the patient were concerned, the real question in the case being one of dollars and cents. In July, 1915, the physician brought suit against Mrs. Levitan and Mr. Gordon, alleging that he had been employed by the former and had performed the operation at her request, and that the latter was cognizant of the fact that the services were rendered and of the necessity therefor; but the case was not brought to trial before the death of Mrs. Levitan in December, 1916, after which the case was discontinued; and in February, 1917, the physician set up the same claim by way of opposition to the provisional account filed by Mrs. Gordon, who was the executrix and sole heir of Mrs. Levitan. It was shown that the physician had been the family physician of Mrs. Levitan and had no acquaintance with Mr. Gordon, but knew that he was a gentleman of very limited means; that Mrs. Levitan brought her daughter to him and requested him to take charge of her; that on November 16 she called him to her house, where her daughter was having convulsions, from kidney trouble; that she was very much excited, and said that she wanted everything done that could be done, and, at her instance, a consultation was had, and the patient was taken to the infirmary, where the operation mentioned was at once performed; that at the infirmary, after the operation, Mrs. Levitan told him to put special nurses on the case, and spare no expense; that he was never, at any time, consulted by Mr. Gordon about the case; and that the services were well worth the amount charged. Attention was called to the circumstance that Mrs. Gordon was present in court when the facts thus recapitulated were testified to, and did not take the stand to deny the truth of the testimony.

The court is of the opinion that the evidence, uncontradicted as it was, and given under circumstances in which it would have been easy and natural for the person most interested to have contradicated it, if she thought that she could conscientiously do so, sufficiently established the employment of the physician by Mrs. Levitan. The provisional account filed by Mrs. Gordon showed only the cash collections which came into her hands, up to the date of its filing, amounting to $9,140.85, against which there were some $4,000 or $5,000 of bills, from which it was inferred that Mrs. Levitan had been engaged in quite an active furniture business. Considering the case as presented, the court finds no sufficient reason for holding that the amount demanded by the physician was unreasonable, or even inconsiderate. Wherefore it is ordered that there be judgment in his favor, recognizing him as an ordinary creditor of this succession, in the sum of $500, and directing that he be placed on the account for that amount, with legal interest thereon from Nov. 16, 1914, until paid.

Allowance for Medical and Hospital Services

(Crescent Coal Co. v. Industrial Commission et al. (Ill.) 121 N. E. R. 171)

The Supreme Court of Illinois holds that, under the workmen's compensation act of the state, an employer was entitled to a credit of but $200, although it expended $744.10 for hospital services, nurses, medicines, physicians, and surgeons in caring for an employee in the illness resulting from his injuries, which terminated fatally. The court says that no question was made but that the services rendered were necessary, and the amount fair, reasonable, and customary for the services performed. They were rendered with the knowledge and consent of the employee and his wife, who became administratrix; and the employer insisted that they should be regarded as part of the compensation. It was not claimed, however, that there was any agreement that they should be so held. On the contrary, the widow stated that she was never told that the amounts were to be taken out of the compensation. If the employer had paid the amount to the widow with the understanding that it was a part of the compensation, it would have been entitled to a deduction of it from future payments, even though it was also understood that the money was to be used for hospital, medical, and surgical purposes, and for nurses, or if it had paid the bills with the understanding that the amount was to be regarded as a part of the compensation it would have been entitled to a like deduction. The employer, however, is not entitled to a deduction for the payment of such expenses without such agreement. A payment made voluntarily or on request must be regarded as having been made gratuitously, or in the expectation of saving the life of the employee or reducing his disability, and reducing the total compensation for which the employer would eventually be liable.

Must Try Suit for Injunction Against Sanatorium

(Giles v. Rawlings (Ga.), 97 S. E. R. 521)

The Supreme Court of Georgia, in reversing an order that refused the plaintiff an injunction, says it appeared from the allegations and prayers of the plaintiff's petition that he was seeking two forms of relief: One wholly to enjoin the operation opposite his residence of a hospital or sanatorium for colored people as being a nuisance per se or in and of itself; the other to prevent its maintenance and operation in such a manner as to constitute a nuisance. As to the latter relief he had no adequate and complete remedy at law, and therefore had a right to invoke the aid of a court of equity. Wherefore, it appearing from the order of the lower court that an injunction was denied solely on the ground that the plaintiff had a complete remedy at law by abatement of the alleged nuisance, and that the court did not pass on the merits of the plaintiff's right to restrain the alleged improper manner of operating the sanatorium, the judgment is reversed, in order that the court below may consider and pass on the facts of the case and determine as to the plaintiff's right to relief.

MEDICAL ASSOCIATION OF GEORGIA

Seventieth Annual Session, held at Atlanta, April 16-18, 1919

The President, Dr. J. W. Palmer, Ailey, in the Chair

Tonsillectomies in the Army

Dr. Richard R. Daly, Atlanta: In my experience the operation of choice is the Beck-Schenk and no dissection. With proper anesthesia it can be done in adults in a large majority of cases. When done carefully, all the tonsil is removed with the least amount of trauma and with risk of hemorrhage reduced to a minimum. In cases in which dissection is necessary, the Douglas knife and the finger are all that are required. The chief advantage of this method is that the educated finger tells accurately what is being done all of the time, and thus there is no need for sponging or other delay, and there is less trauma than in any other dissection method.

Thirty-four young men who were not making good in their training because of defective breathing were operated on and restored to their commands in condition to complete their instruction and to go to the field. These men would otherwise have been dropped from the rolls.

Removal of Tonsils

Dr. Arthur G. Fort, Atlanta: We use two instruments in enucleating the tonsils, (1) the modified Beck fenestrated protected snare and (2) the Beck with the ordinary snare attachment. The preparation of the patient begins about one week before operation. He is given calcium three times a day to increase the coagulability of the blood, and often the general condition of the tonsil is much improved by the treatment. I prefer general anesthesia, preferably ether, unless there are contraindications.

DISCUSSION ON PAPERS OF DRS. DALY AND FORT

Dr. William C. Lyle, Atlanta: There are indications against the use of general anesthesia in some cases, so that occasionally we have to resort to local anesthesia; but all things considered, general anesthesia is preferable for tonsillectomy. I do not remove both tonsils at the same sitting. I remove one and then wait a week before removing the other.

Dr. H. W. Terrell, LaGrange: I agree with Dr. Daly that tonsillectomy should be done under general anesthesia. In the last three years I have operated in only one case under anesthesia. Dr. Lyle stated that he removes one tonsil and then waits a week before removing the other. If he is able to get the patient to return for the removal of the second tonsil he has been more fortunate than I have been.

Dr. R. R. Daly: If we can remove the tonsils without trauma under general anesthesia and can induce the patients to have both tonsils taken out at the same time, we should do so.

Dr. A. G. Fort: I cannot agree with Dr. Terrell that we should always remove the tonsils under general anesthesia. In some instances you must do so under local anesthesia. A few days ago the vocational board referred to me a man who had tuberculosis. To give him a general anesthetic would endanger his life very much, and to allow the tonsils to remain as they were would reduce his vitality, and therefore also endanger his life.

Radium Therapy for Uterine Hemorrhages

Dr. O. D. Hall, Atlanta: I have used radium in seventy-five malignant cases. Seventy-four cases were inoperable; one case was operable. This patient is living, is in good health, and has had no more hemorrhages since the first application of radium. Of the seventy-five cases treated, the hemorrhages of ten patients were not controlled; five of these had had a hysterectomy. At the time of treating these patients, each had an extensive recurrence, extending into the pelvis. In fifteen of the seventy-five cases the cautery was used. Of the seventy-five cases a history was obtained of uterine hemorrhages of from one to six years' duration before the malignancy was discovered. None of the nonmalignant cases treated by radium have had malignancy to date. This report runs over a period of three years.

DISCUSSION

Dr. L. C. Allen, Hoschton: A striking feature in these cases is the length of time the uterine hemorrhages had existed before treatment was instituted. Uterine hemorrhage from a woman, especially at the menopause, is a matter of grave consideration. Every case should be investigated thoroughly and patients should be taught that any hemorrhage, any excessive menstruation occurring at this period of life, should receive just as serious attention as if it occurred before the menopause or after the menopause. These hemorrhages sometimes are attributed to the menopause, when, as a matter of fact, they are due to something else, frequently a very important pathologic condition that should receive very careful and painstaking investigation

Medical Inspection of Schools

Dr. M. M. McCord, Commissioner of Health, Rome: After visiting the public schools for two years I found that about 25 per cent. of defective children were unable to pay a physician or dentist for correcting their defects. It was decided that to meet the demands of such conditions, a children's free clinic must be established. A quick response followed from every organization in the city and county when the purpose of the clinic was explained, so in a very short time all necessary funds were in hand. The surgical, medical and dental outfits were purchased and the clinic located in the municipal building. Every physician and dentist in the city volunteered his services to the clinic. A competent clinic and a follow-up nurse were employed. Since the children's clinic opened, July 1, 1918, about 400 children whose parents were not able to pay have been treated at this clinic.

Health Organization

Dr. M. F. Haygood, director, Division of Rural Sanitation and Epidemiology, Atlanta: The commissioner of a health department must be able to get the maximum of service from each member of his department. He should have frequent conferences with the members of his force. His clerk should be able to write letters and keep accurate records. She should be taught how to examine for hookworm, also to do malarial and other bacteriologic microscopic work. The school and community nurse should assist in all school examinations and be taught how to find all physical defects. She should do follow-up work to see if the defects are corrected, and if not, make every effort to have this done. She should do child welfare work and look after the tuberculous. The sanitary inspector should be armed with a code of sanitary regulations and inspect frequently all spaces where food and drink are handled. He should also visit all country or suburban homes not having sewerage nor sanitary closets, and persuade the owners of such homes to install these sanitary conveniences.

The Feeding of Babies During Acute Illness

Dr. W. A. Mulherin, Augusta: In all acute febrile diseases the baby should be given less food and more water than in health. In bottle-fed babies this can be easily accomplished by simply increasing the dilution of the food. In breast-fed babies less food can be given by shortening the length of time at breast, lengthening the intervals between nursings and giving water freely between nursing hours. Sick babies tolerate fats very poorly, therefore this ingredient of the food should be reduced, or excluded temporarily. Intolerance to fats lasts much longer than intolerance to carbohydrates and proteins. Therefore, sick babies, artificially fed, should receive formulas made up from fat-free milk, or from skimmed milk containing from 1 to 3 per cent. of fats. As fats and carbohydrates are interchangeable for a short time without being detrimental to the baby's health, the diet should consist largely of carbohydrates, such as barley water, rice water, or gruels made from carbohydrates.

Do not attempt to cure an acute illness, and at the same time fatten a baby; the two things are practically impossible of accomplishment. It is just as important to observe regular hours of feeding, in cases of sick babies, as it is to carry out such procedure with well ones. Ordinarily, however, food should not be given oftener than at three-hour intervals. Some infants and children are so acutely ill that they will refuse all food for several days, and it is only with great difficulty that enough water can be introduced into their system to prevent serious conditions arising from dehydration of tissues. In such cases forced feeding with tube and rectal drip, with 5 per cent. glucose solution, will be found life saving. In babies about 1 year of age, or older, I have found buttermilk to be of great value in feeding during acute illness. It has the advantage of not forming large, tough curds in the stomach, as is so frequently the case when raw cow's milk is used. The reason is that the casein in buttermilk is a lactate of casein, and the rennet of the stomach does not act on it to coagulate it into curds.

Congylonema Scutatum

Col. Charles Wardell Stiles, Fort McPherson: A short time ago Prof. Henry G. Ward of the University of Illinois had a parasite submitted to him from a patient in Arkansas. The patient was a girl, 16 years of age, who showed considerable digestive disturbance, vomiting, nervousness and fever, for a number of months. Finally, a small thread worm was discovered crawling around under the mucosa in her mouth. This worm was extracted and she recovered. Ward believes that this parasite is identical with the parasite found in the esophageal wall of swine.

Just before America entered the war a specimen was sent to me for investigation from Bushnell, Fla. It came from a white girl, 13 years of age. About a year previously she began to have fever of a very irregular character, accompanied by nervous disturbances, and other symptoms. Many diagnoses were made of her case. Finally this thread worm was discovered in her mouth. It was extracted and she recovered her health. These are the only two cases of this particular thread worm that are known. It is well worth while for physicians to be on the lookout for such cases even though they are rare, for in irritable, nervous children these parasites may be present.

Effect of Influenza on Arrested Pulmonary Tuberculosis

Dr. Arch Elkin, Atlanta: Out of the entire number of influenza cases seen by me, I have selected seven. Four of these patients had been under treatment previously for active tuberculosis. The other three patients showed on recent examination active physical signs of pulmonary tuberculosis in addition to manifest evidence of healed lesions. This evidence was corroborated by means of the roentgen ray. It is not surprising that influenza reactivates arrested or apparently cured lesions of tuberculosis. One of the interesting points, however, is the fact that many cases observed, both in private practice and otherwise, show a reactivation of the primary lesions, which in most instances is confined to the apexes, and in addition positive activity in the base of the lung.

What We Have Done in Georgia to Aid in the Control of Venereal Diseases

Dr. Joseph P. Bowdoin, Surgeon, U. S. P. H. S., Atlanta, Ga.: In our campaign for the control of venereal diseases, we decided that education of the masses, of the young men in particular, was of the greatest importance. Other measures adopted were: free Wassermann and laboratory diagnosis, with free arsphenamin to those not able to pay for it; reporting by physicians to enable us to place infections and to keep track of the itinerant carrier; organization of clinics and aid in conducting them, that free treatment could be given in the more populous centers, especially near cantonment zones where the population was dense; repressive measures; closing the red light districts as a war measure (they should be kept closed forever). We have been endeavoring to have the necessary laws enacted by the state and cities to suppress prostitution and control the sources of infection. In our educational campaign we have addressed over 80,000 people. We have shown the government moving picture "Fit to Fight" to men only and women only in a number of the larger towns.

*Roentgen Ray and Radium in Treatment of Basal Cell Epithelioma. G. M. MacKee, New York.—p. 119.
Roentgen Ray Indications for Tooth Extractions. B. C. Darling, New York.—p. 136.
Gas Gangrene of Leg Due to B. Welchii: Case Diagnosed Roentgenologically. F. A. Sprague, Camp Zachary Taylor, Ky.—p. 145.
Mechanics of Stomach After Gastro-Enterostomy. J. T. Murphy, Toledo.—p. 148.
Roentgenographic Study of Osteitis Deformans. C. W. Perkins, New York.—p. 151.

Roentgen Ray and Radium in Treatment of Basal Cell Epithelioma.—Of the 258 patients treated by MacKee, 222 remained under observation for at least a few months. Among these 222 cases there were 201 clinical cures, or 90 per cent. Fifteen patients were improved; in six instances, the lesions were not even benefited. The cases were not selected. Among 158 cured cases observed for periods of *from six months* to five or more years there were twenty-four relapses, leaving a total of 85 per cent. of possible permanent cures. Sixteen cases were *observed for* five years or more with only one relapse, or about 94 per cent of supposedly permanent cures. Forty-six cases remained under observation for four years. In this series there were nine relapses, leaving 80 per cent. of probable permanent cures. *Seventeen cases* were followed for three years in which there were three recurrences, or 82 per cent. of cures. Of the two-year cases (about two years), there were thirty-two, with five relapses, or 84 per cent. of cures. Thirty-four cases were observed for about one year with five recurrences, or 85 per cent. of cures. Thirteen cases were followed for six months, with one *relapse*, 92 per cent. of cures. Finally, forty-three cases were observed for from one to five months. In this series there were no relapses. Nineteen of the twenty-four patients with relapses were treated again with the roentgen ray, and seventeen recovered. *The two patients who did not respond to the roentgen ray also did not improve under the influence of radium.* Two of the patients *with* recurrences were cured with radium and two by *surgical incision. In five cases relapses occurred a second time within a year after the second recovery. In four of these cases the lesions again disappeared under further* roentgen-ray treatment; *one patient failed to respond either to the roentgen ray or radium. From this it will* be seen that a *relapse should* not cause unnecessary alarm.

American Review of Tuberculosis, Baltimore

April, 1919, 3, *No. 2*

**Tuberculous* Infection. II. Description of Plastic Models (Reconstructions) of *Conglomerate* Tubercle and *Surrounding* Structures in Human Lung. W. S. Miller, Baltimore.—p. 65.
*Fundamentals of Nutrition of Tubercle *Bacillus: Utilization of Some* Amino-*Acids and* Ammonium Salts. E. R. Long, Saranac Lake, N. Y.—p. 86.

*War Against Tuberculosis. W. C. White, *Rome, Italy.*—p. 118.

Reconstruction of Conglomerate Tubercle and Surrounding Structures.—*A description of plastic models of a tubercle* and the surrounding *framework in a human lung is given by Miller. The tubercle came from the lung of a man* who had died of pulmonary tuberculosis. It was situated at the periphery of the lung but did not extend to the pleura. It was sectioned serially and the outlines of each of the seventy-six sections of the series were drawn, magnified 50 diameters, on separate sheets of paper and then transferred to wax plates and the various parts cut out. By this method of study it was found that the tubercle did not belong to any single system of air spaces. It lay between two bronchioli and involved the respiratory bronchioli that arose from the right side of the other bronchiolus, together with their alveolar ducts and many of their atria and alveolar saccules. Many of the latter were greatly reduced in size, while others were greatly dilated. The deformity of the air spaces was so great that they were often *difficult of identification.* This deformity was to a large extent due to the mechanical pressure exerted by the tubercle or to the closure of the openings by which the air spaces communicated with the bronchial tree.

Metabolism of Tubercle Bacilli.—Long reports the results of studies which he has made on the chemical interactions that go on between tubercule bacilli and various mediums on which the former were grown. The tubercle bacillus was grown on a pepsin digest of casein and on biuret-free trypsin and acid digest, much better growth taking place on the former, characteristic proliferation occurring, however, on the latter. Nitrogen analyses of inoculated peptone mediums showed a withdrawal from the mediums of both peptone and amino-acid nitrogen, with a *production of ammonia.* Good growth occurred on glycerol-sodium-chlorid-phosphate mediums containing tenth-molecular concentration of urethane (ethyl ester of amino-formic acid), glycerol (*amino*-

acetic acid), and alanin (amino-propionic acid). The acid amids were also readily utilizable. The corresponding ammonium salts of fatty, ketone, and hydroxy acids did not permit growth. The amins of the three acids mentioned, that is, ammonia, methyl amin and ethyl amin, afforded good growth when used in the form of their hydrochlorids. Methyl and ethyl alcohols were added to ammonium chlorid mediums with advantage. The ammonium salts of the dibasic acids, oxalic, malonic, succinic, malic, and tartaric acids, yielded excellent growth. The course of nitrogen metabolism in a medium containing as its source of nitrogen the dibasic amino acid amid asparagin, was followed, and the amid group was found to be the one chiefly attacked, liberation of ammonia from this group taking place while the amino group was almost untouched. In the monobasic series, the amino group is more readily used than the amid.

Differentiation of Early Tuberculosis from Hyperthyroidism by Epinephrin Test.—For three years Goetsch has been practicing the subcutaneous injections of 7.5 minims of a 1:1,000 solution of epinephrin chlorid in patients who present marked symptoms of hyperthyroidism, but in whom no positive diagnosis can be made by ordinary methods of examination. If the patient, following the epinephrin injection, reacts with manifest symptoms of hyperthyroidism, Goetsch believes that a positive diagnosis of the condition is justified. At the Trudeau Sanatorium, Nicholson and Goetsch tested forty patients by this method. Of eighteen patients whose diagnosis was "clinical tuberculosis, questionable," ten reacted positively and eight negatively; of sixteen with a diagnosis of "clinical tuberculosis, inactive," nine reacted positively and seven negatively; and of six with active clinical tuberculosis, none reacted positively. The authors conclude that the test is a valuable aid in determining whether the disease from which patients are suffering is purely a tuberculosis, a tuberculosis complicated by hyperthyroidism, or a pure hyperthyroidism. Hyperthyroidism, whether or not associated with tuberculosis, will give a positive reaction to epinephrin. Tuberculosis, uncomplicated by hyperthyroidism, does not react positively to epinephrin. They feel that in a considerable number of border-line cases presenting symptoms more or less characteristic of both conditions, they can now pick out those suffering with hyperthyroidism.

War Against Tuberculosis.—White summarizes some impressions that he has obtained as the result of his experiences in antituberculosis organization in France and Italy during the war. He mentions the conditions that are peculiar to each country involved and insists that to be satisfactory organized efforts must not necessarily follow a fixed model but must fit local conditions. In France, England and America the trend is to centralize the administration of all public health problems in a ministry of health. This centralization has not yet become a burning question in Italy, but even with this centralization of power there must come, if the problems are to be handled properly, such an immediate decentralization as will make it easy for the province and city to undertake their own problems, with a maximum of liberty in the development of the equipment necessary to handle their task.

*War Neuroses as Physiologic Conservations. S. I. Schwab, St. Louis.—p. 579.

Fat in Cerebral Cortex.—Three apparently normal brains from persons of about the same age and of the same sex were examined by Raeder. One of the specimens was obtained from a case in which trauma caused the death. In the other two cases, death was due to bronchopneumonia. In both these cases there was a slight edema of the pia-arachnoid membranes. The consistency of both brain specimens was said to be normal. The somatic changes were similar, being due to an acute bronchopneumonia in both cases. Besides this there were acute changes in the liver, kidneys and spleen, and in one case slight hypertrophy of the heart with some dilatation of the right side. Twenty blocks were selected for microscopic examination from each hemisphere, after treatment with Marchi, sudan III, cresylecht-violet and Weigert staining methods, making forty sections of each brain, or 120 in the three cases. This report deals with the Marchi and sudan III reactions. Fat was found by far more frequently in the fourth and sixth layers —from 63 to 80 per cent.; the next most frequent location being the seventh zone—25 per cent. Fat was found in negligible amounts in the first, second and fifth layers. In the two cases with terminal infection there was a remarkable increase in fat in the third and seventh layers—from 53 to 65 per cent.—as against 7.5 per cent. in the third layers, and 25 per cent. in the seventh layer of the apyretic case. Higher temperatures apparently affect the third and seventh layers. The fat was found irregularly distributed in the cells, both in a general way, in the periphery. The nucleus was never displaced. In some instances the pigment was found bunched at one end or on one side of the cell, sometimes in the fundus, sometimes encroaching on the axon. In other instances, it was more evenly scattered about the periphery of the cell. It was found in the form of minute droplets of varying sizes. The droplets do not coalesce, but keep their spherical form even when closely packed at a given point. Fat was found more generally in the vessels of the cortex, but less frequently in the white matter. The fat was not found in droplets, but it seemed to coalesce and appeared in variously shaped and irregular masses, often at bifurcations or near branches, being irregularly distributed, some twigs being entirely fat free. This irregularity may be correlated with the peculiar anatomic structure of the cerebral vessels.

Peripheral Nerve Injuries.—The purpose of this paper is to place on record the methods used in caring for peripheral nerve cases in the American Red Cross Hospital No. 1, formerly the American Ambulance, and to report the results following nerve suture. There are available for statistical purposes 857 histories of peripheral nerve injuries, with the records of 205 reparative nerve operations, 151 of these having been followed during convalescence for at least six months after operation. An analysis of these records shows that the musculospiral was the nerve most frequently injured in war; the ulnar nerve was involved nearly as often. Following operation, the musculospiral and sciatic nerves make the best recoveries, the results in the case of the sciatic being equally as good as those of the musculospiral. The condition of an injured nerve, when examined by sight and touch at the time of operation, is invariably worse than the previous clinical findings would lead one to expect. When at the time of operation, having utilized all the methods to determine whether simple liberation or excision and suture is the best procedure, if doubt still exists, excise and suture. Repair of an injured nerve as early as possible should be the aim of every surgeon. For this reason the authors urge that in time of war neurologists should be stationed close to the front, so that the wounded may be examined for nerve lesions before going to the operating room. This, by increasing the number of primary nerve sutures, will unquestionably lead to a higher percentage of recoveries. Patients convalescing from nerve reparation should be encouraged to use the extremity affected because volitional effort plays a part in the return of the function. The more respect the surgeon shows nerve tissue when repairing an injury the better will be his results. The nerve should be stripped and handled as little as possible and the ends should be approximated so as to place in apposition corresponding fasciculi of the cut nerve.

War Neuroses as Physiologic Conservations.—This paper sets down in a permanent fashion the story of the effort made by the neuropsychiatric service of the A. E. F. to meet and combat the war neuroses. It has to do with matters of organization and the development of a point of view. It is largely with the latter that Schwab feels that he is properly concerned. The observations were made in Base Hospital No. 117, which was the special hospital for war neuroses at La Fauche. Schwab was medical director of this hospital from its beginning.

*Vincent's Angina of Penis. S. P. Bond, Little Rock.—p. 226.

Vincent's Angina of Penis.—Bond reports a case of ulcer at the mucocutaneous junction of the foreskin, which rapidly spread with the formaton of two more ulcers. There was marked edema, the ulcers had a grayish, sloughing bottom, ragged, irregular, undercut edges, with a foul discharge. Glandular enlargement was not present. A smear from the exudate of this lesion stained with Gram's stain, showed the fusiform bacillus, the thread-like organisms found in the so-called angina of Vincent, and the larger spirilla characteristic of the forms designated by Flügge as vibrios. Intercourse was admitted by the patient, saliva having been used as a lubricant.

*Neurosyphilis: Special Points in Symptomatology and Course. A. Myerson, Boston.—p. 499.

Neurosyphilis. — Five cases are reported by Myerson because they represent somewhat unusual and yet rather important phases of neurosyphilis. The first case points out the importance of spinal puncture. The blood remained negative during many examinations while the spinal fluid was constantly positive. In the second case the Brown-Sequard syndrome appeared in almost classic purity. Moreover, the spinal fluid showed the xanthochromia syndrome. In the third case a mental disease apart from the neurosyphilis manifested itself almost as if the neurosyphilis were not present, while the neurosyphilis gave practically no symptoms. The fourth and fifth cases are important because they affect a brother and a sister. The brother, a paretic clinically, was treated and had a fine remission of clinical symptoms, but the spinal fluid was unchanged. The sister, presenting none of the signs of paresis, was treated for a long time for orthopedic symptoms. She presented in her spinal fluid the syndrome of paresis. Myerson emphasizes the fact that these cases form a group, which, though each is individual and unusual, is characteristic of neurosyphilis in the wide range of symptoms presented.

Effect of Bile on Clotting Time of Blood.—This is a report of an investigation made by Haessler and Stebbins on whether or not bile or bile salts, present in the blood in jaundice, are in themselves capable of causing the increase in the coagulation time. They found that within certain limits clotting time depends on the percentage of bile present in solution and that the reaction is the same in experiments with pure solutions of the substances concerned in coagulation, as in whole plasma. Apparently bile and bile salts do not interfere with the formation of thrombin, since the prolongation of clotting time is just as great when preformed thrombin is added in ample quantity to fibrinogen solution, as when thrombin must be formed from its precursors in the presence of bile. It was found that there was a retardation of clotting, great enough to be detected by clinical methods, with amounts of bile greater than 5 per cent. The relation of bile pigments and bile salts in the blood in janudice has not been determined, but to the authors it would seem possible for the salt to be present in sufficient concentration to prevent clotting.

Prophylactic Vaccination Against Pneumonia at Camp Wheeler.—At Camp Wheeler 13,460 men, or about 80 per cent. of the entire camp strength, were vaccinated against pneumonia with pneumococcus lipovaccine. The dosage employed in all cases was 1 c.c. of the lipovaccine, containing approximately 10 billion each of Pneumococcus Types I, II and III. Both the local and general reactions produced by the vaccine were usually mild. Only 0.7 per cent. of those who received the vaccine were sufficiently affected to need hospital care. None of these men was seriously ill, and a majority of them returned to duty on the second or third day after admission. Most of the troops inoculated were under observation for two or three months after vaccination. During this period there were thirty-two cases of pneumococcus Type I, II and III pneumonia among the vaccinated four fifths of camp, and forty-two cases of pneumonia of these types among the unvaccinated one fifth of camp. However, if all cases of pneumonia that developed within one week after vaccination are excluded from the vaccinated group, there remain only eight cases of pneumonia produced by fixed types, and these were all secondary to severe attacks of influenza. There is no evidence whatever that pneumococcus vaccine predisposes the individual even temporarily toward eithe pneumococcus or streptococcus pneumonia. The weekly incidence rate for pneumonia (all types among the vaccinate troops was conspicuously lower than that for the unvacci nated troops. The pneumonia incidence rate per thousan men during the period of the experiment was twice as hig for unvaccinated recruits, and nearly seven times as hig for unvaccinated seasoned men as for seasoned men. Influenz causes a marked reduction in resistance to pneumonia eve among vaccinated men. Of the 155 cases of pneumonia (a types) developing one week or more after vaccination, 13 were secondary to influenza. The death rate for 155 cas of pneumonia (all types) that developed among vaccinat men one week or more after vaccination was *only 12.2* p cent., whereas the death rate for *327* cases of *all types* th occurred among unvaccinated troops was *22.3* per cent. Th death rate for primary pneumonia among vaccinated troo was 11.9 per cent.; among unvaccinated troops it was 31 per cent., almost three times as great. On the other han the mortality rate in pneumonia secondary to influenza about the same for the vaccinated and unvaccinated troo

Action of Strophanthin on Heart.—In the experiments ma by Levine, in which crystalline strophanthin was inject intravenously, the amount of the drug needed to produ toxic results as shown electrocardiographically was prac cally independent of the speed of administration. Injectio of the drug were made at various speeds, with intervals four or more days between experiments. The total amou required to produce the toxic effect did not vary significant A theory of the action of strophanthin is formulated Levine which reconciles the conflicting views relating to t importance of concentration and of total amount of the dr It supposes that the time required to produce a given eff in a heart varies inversely with the concentration of t active principle. The heart utilizes only a small portion the neighborhood of 10 per cent.) of the drug to which it exposed, no matter what the concentration. A toxic eff results when the heart has taken up a certain total amo of the drug which is a definite small fraction of its o weight. If this theory is correct, it explains why in conc trated solutions the total amount is not important, for small part that is taken out by the heart does not apprecia alter the concentration, while when very dilute solutions small quantities are used the amount taken up by the he diminishes the remaining concentration appreciably; that the "digitalis pressure" becomes lessened. In these experime the rapid injections forced an adequate amount of strophanthin into the heart rapidly and produced the toxic effect; in the slow injections the same total amount of drug was taken up by the heart, only more slowly. Levine claims that these experiments have an importance in clinical medicine. They suggest a method for intravenous medication with strophanthin designed to reduce the danger due to using the drug. After the ventricles have fibrillated, there is no constant way of reviving a heart. Occasionally, as in one experiment, resuscitation may take place after ventricular fibrillation and standstill by massage of the heart without opening the chest. No opinion is offered on the practical value of this method.

Influenza Treated with Serum from Recovered Cases.—Three cases of influenza, two complicated by pneumonia, were treated by Miller and McConnell with injections of serum obtained from persons convalescing from pneumonia. The results of this treatment lead the authors to believe that the injection of serum from recovered patients into desperately ill patients infected with the same organism is logical and is of some value.

Carcinoma of Esophagus.—The following case reported by Hyman is interesting because the diagnosis was made only at the postmortem, although the carcinomatous process had involved the entire lower portion of the esophagus and the adjacent structures. A man, aged 58, in apparently good health entered the hospital for the relief of a large swelling in the right side of his neck which caused him no trouble, save that he was forced to wear larger collars than had been his custom. With the exception of the mass in his neck the physical findings were practically negative. Because of its acute onset, a tentative diagnosis of septic cervical adenitis was made, although the absence of pain and tenderness could not be accounted for. Malignancy was suggested, but examination of the the lips, gums, tongue, tonsils and oropharynx failed to reveal the site of any primary malignant disease. Roentgen-ray examination of the chest showed nothing remarkable in the lungs. Examination of a piece of tissue removed from the mass showed it to be cancer of the medullary type. Death ensued three months later. Postmortem examination disclosed tremendous involvement of the lower part of the esophagus and adjacent structures by a malignant growth which had not been recognized or even suspected previously, showing that an extensive pathologic process can occasionally involve the esophagus without that organ responding in its usual immediate fashion, and that unexplainable malignant disease of the right cervical glands may be secondary to "silent" esophageal carcinoma.

Meningitis.—Goldestin reports five rather interesting cases: one, a tuberculous meningitis occurring in an adult; the second, meningitis in a new-born infant; the third, epidemic cerebrospinal meningitis in a young child; the fourth, tuberculous meningitis in a 17-year-old boy; the fifth case, meningismus, or nonbacterial toxic meningitis, complicating otitis and bronchopneumonia in a 3½-year-old child, with a brief discussion of the symptoms and more important diagnostic and therapeutic features of meningitis in general.

Influenzal Pneumonia Treated by Blood Transfusion.—Citrated blood, taken from patients recently recovered from influenzal pneumonia, has been injected by Bogardus in six cases, and the results have been favorable. The author claims that the death of these two cannot be held against the method, however, as in one case it was not done until twelve hours before death, and in another case the patient was so far away from town that he could not be properly watched. In the four patients who recovered the results were immediate and certain.

Lethargic Encephalitis.—The authors report a series of experiments performed in an attempt to establish the etiology of epidemic lethargic encephalitis. Inoculation of emulsion of human brain produced lesions in the monkey characteristic of the lesions found in epidemic lethargic encephalitis. The inoculation of the filtrate of the mucous membrane of the nasopharynx of a patient not suffering from epidemic lethargic encephalitis produced no evidence of disease in the monkey. The inoculation of the washings of the nasopharynx in a case of epidemic lethargic encephalitis produced paralysis in the monkey accompanied by pleocytosis in the spinal fluid. A filtrable virus obtained from the mucous membrane of the nasopharynx in a fatal case of epidemic lethargic encephalitis produced hemorrhagic encephalitis in the monkey. This virus has been carried through a second generation.

Pancreatic Lymphangitis.—Deaver emphasizes the importance of early surgical treatment of upper abdominal disease before a possible pancreatitis has time to get in its destructive work. Cases in support of this view are cited.

Permanent Colostomies.—Abstracted in The Journal, Jan. 18, 1919, p. 1219.

Treatment of Hodgkin's Disease.—Abstracted in The Journal, Jan. 18, 1919, p. 1220.

Ectopic or Pelvic Kidney.—Nineteen cases of ectopic kidney are recorded by Judd and Harrington. In nine of these, operations were done because of pathologic conditions in the misplaced kidney. In the remaining ten cases the condition was discovered either during the course of some other operation or in making a routine examination of the kidney. In these ten cases the kidney, while misplaced, was not producing any symptoms and apparently was functioning normally. When the ectopic kidney is pathologic, the symptoms are the same as when the condition is present in a normally placed kidney. The diagnosis depends on the physical findings, the roentgen ray and the kidney examinations. The differential diagnosis is more difficult in the female than in the male because of the frequency with which the ectopic kidney causes symptoms referable to the adnexa. The most common error in diagnosis in the male has been in differentiating between the dystopic kidney and inflammation in the appendix. From a surgical point of view the treatment of ectopic kidney differs in no essential from the treatment when the organ is in its normal position. The problems presented by the ectopic kidney during pregnancy and parturition are often difficult to decide, but fortunately most deliveries are accomplished without surgical intervention. The surgical treatment of pathologic conditions in the ectopic kidney is practically the same as for like conditions in normally placed organs.

Malignancy Following Operative Treatment of Undescended or Maldescended Testis.—The question of whether the traumatism incident to the operation on the undescended testis might not favor the development of malignant disease, Coley says, is one that should be considered, although at present it cannot be answered definitely. In none of the 415 cases in which operation was done at the Hospital for Ruptured and Crippled during the past twenty-nine years, has malignant disease been known to develop; however, Coley has observed one case of sarcoma of the testis in which the disease was either present at the time or developed shortly after the operation for undescended testis. The end-results in this case show that it is possible to cure the hernia in practically all cases. The result accomplished by the operation, the cure of the accompanying hernia, would seem to justify advocating operation for the undescended testis in adults.

Prostatectomy.—Abstracted in The Journal, Jan. 18, 1919, p. 1218.

Polyposis of Stomach.—Only one case of this kind has been seen at the Mayo Clinic in approximately 69,000 abdominal sections, 8,000 of which were for gastric lesions. A correct diagnosis was established before operation. From a study of this case, in conjunction with such cases described in the literature, it would appear that gastric polyposis has sufficient characteristics to be classified as a separate entity and should not be classified with single polyps or papillomatous masses (the latter usually malignant) occasionaly found in the stomach, and to which the term gastric polyposis has at times erroneously been applied. Balfour emphasizes that the condition would have been quite unsuspected had it not been for the roentgenogram and its interpretation. The age of the patient, 31 years, is unique because it is the earliest age at which the condition has been recognized.

Two Signs in Chronic Appendicitis.—Abstracted in The Journal, Jan. 25, 1919, p. 309.

Congenital Diverticula of Intestines.—Abstracted in The Journal, Jan. 18, 1919, p. 1219.

New Growths of Testis.—In considering tumors of the testis O'Crowley and Martland direct attention to the fact that nine times out of ten the tumor is malignant and that early diagnosis and radical treatment are of prime importance in order to prevent metastasis and consequent death. They report thirteen cases. Of these, seven patients are dead from metastases. The youngest patient was aged 5½ years, the oldest, 52 years. The longest duration of the disease was two years and seven months; the shortest, ten weeks. In six cases a definite history of trauma was given. In one case an undescended testis was the seat of the growth. Among 110,000 male patients admitted to a number of London hospitals during a period of twenty years there were sixty-five cases of malignant disease of the testis. Of fifty-seven cases with complete histories, nine were in ectopic testes. In 182,729 male admissions to general hospitals of New York City there were three cases of malignant growth of intra-abdominal testes, or about one in each 60,000 cases.

Radical Operations for Teratoma Testis.—Hinman emphasizes the relative simplicity and the real necessity of radical measures in these cases, and, by way of demonstration, reports five successful cases; four of the patients would certainly have died from metastases if simple castration alone had been performed, and in all of these the operative difficulties were not great and the postoperative complications insignificant. Hinman dissects the lymphatic tissues from off the iliac vessels and aortic bifurcation and the preaortic lymph areas and spermatic vessels. In every one of his cases there were masses of lymph tissues lying on the external and common iliacs as far up as the aortic bifurcation. This area had to be cleaned separately from the spermatic vessels. All five patients enjoy perfect health now nine months, seven and one-half months, four months, three months, two months and three years and six months, respectively, since operation. The finding in four cases of metastatic tumor demonstrates the uselessness of simple castration and the necessity of radical surgery.

*Nomenclature of Crucial Ligaments. G. A. Sampson.—p. 190.
Prevention of Pneumonic Influenza. N. W. Mackwill.—p. 190.

Syphilitic Factor in Insanity.—In Lind's opinion it would be absurd to claim that syphilis is the cause of every case of insanity, but it would be absurd to deny the alarming frequency of the combination of psychopathic inheritance and acquired or congenital syphilis. The age of the general paralytic (acquired) used to be somewhere about 49, but, judging by the postmortem examinations of the last few years, it seems to be gradually approaching 30. In other words, syphilis is acquired almost before the youth is mature. To Lind it looks as if the stone, bronze, and iron ages will be recognized by posterity as being followed by the syphilitic age. For the sake of the ignorant, he suggests the use of posters warning concerning venereal disease.

Nomenclature of Crucial Ligaments.—Sampson suggests that a more rational and more informative naming of the crucial ligaments is as follows: taken from the position of attachment of each ligament on, first, the proximal, and then the distal articulating bone: Posteroanterior (or longer) crucial ligament; posteroposterior (or shorter) crucial ligament, for both ligaments are attached proximally, each at its own separate area, at the posterior of the femur within the intercondyloid notch. The one runs downward, inward, and forward, to be attached to the tibia near the front of the joint, in front of the tibial spine, while the other runs downward, outward, and backward, to gain attachment at the hinder part of the tibia, close to the popliteal notch.

*Gauze Mask: Some Experiments. R. F. Llewellyn.—p. 214.
Congenital Defects in Lower Bowel Recurring in Three Successive Children of One Family. A. S. Walker.—p. 216.

Bacteriology of Present Influenza Epidemic.—Bacteriologic examinations were made by McMeekin of thirteen smears and cultures of sputums, seven cultures taken from lungs postmortem, and twenty blood cultures. The predominating organisms found in sputums have been influenza bacilli, gram-positive diplococci resembling pneumococci and indistinguishable from them, and *Micrococcus catarrhalis,* all in large numbers. Coccal forms have also been present. Cultures taken from the lungs direct postmortem have shown influenza bacilli, pneumococci, *M. catarrhalis,* streptococci and staphylococci in a majority of cases. Of the twenty blood cultures examined, three showed *Staphylococcus albus,* probably a contamination, four showed tiny gram-negative bacilli morphologically indistinguishable from influenza bacilli, but showing cultural differences, while one showed Friedländer's bacillus.

Gauze Mask.—It has been suggested that the saturation of the inner layers of the mask for some hours by the moisture of the breath may tend to determine the majority of the bacilli caught in the mask to the inner layers thereof, and that if the mask be then allowed to become dry and be reapplied before death of the bacilli occurs, the wearer may get a sudden and large dose of them. Llewellyn therefore suggests that after the mask has been washed, sterilized and dried it be dipped in a weak solution of glycerol in water, say 5 per cent., and again hung up for some hours. All the water which the hygroscopic glycerol could not hold would then have evaporated, leaving the mask very slightly moist, while the antiseptic qualities of the glycerol would be unfavorable to the multiplication of the bacilli in the mask. A trace of thymoil might be added to the glycerol solution.

Recent Epidemics of Acute Encephalo-Myelitis.—This so-called "mysterious disease," which first made its appearance in New South Wales, Queensland and Victoria, and which was reported by several clinicians in 1917, is not the same as epidemic lethargic encephalitis, in the opinion of Cleland and Campbell. They believe that the acute encephalomyelitis under discussion is a distinct and hitherto unrecognized entity resembling ordinary infantile paralysis and at the same time histologically resembling hydrophobia. The disease is always present in sporadic form. Investigations carried out during 1918 by Cleland, Campbell and others seem to give strong support to the contention that the disease is a hitherto unrecognized entity. The points to which attention is specially directed by the authors are the following: There is no record of an epidemic of acute poliomyelitis in which signs of cerebral irritation have so strikingly dominated the clinical course, nor of one in which there has been such a high mortality rate (70 per cent.), nor of one in which such a large proportion of adults have fallen victims. Histologic examinations of the brain and spinal cord from sixteen human cases and from various experimentally infected animals have all shown lesions of a similar and, as regards distribution, distinct kind. The first and most important change is a thickening of the veins. The vein wall is surrounded by a collar or sheath or sleeve of cells which sometimes fills and distends the perivenous space. The vessels so affected may be found apparently in any part of the brain or spinal cord, though not necessarily in the same situation in all cases. Some vessels may be affected and others escape. In early cases most of these cells are indistinguishable from lymphocytes, though interspersed among them may be some cells of fixed connective tissue origin. Later the cells may show more protoplasm and an indented nucleus—a stage toward organization. In addition to these perivenous sheaths, there is intense congestion of all vessels and sometimes evidence of stasis. As secondary phenomena degeneration of nerve cells may occasionally be found, probably due to interference with their nutritive supply.

The disease in monkeys, of which the authors have had twenty examples under observation, seems not to agree with that described in these animals when infected with the virus of ordinary infantile paralysis. Altogether nineteen of the twenty monkeys showed varying degrees of incoordination, and thirteen, including twelve of the nineteen, exaggerated muscular movements or convulsions. On the other hand, fourteen monkeys showed paresis or paralysis, consisting of slight paresis of a limb in three, marked paresis in five and apparent paralysis of a limb or other part in six. In two monkeys ptosis was marked and in one it was slight. Two showed squint. In no instance was the disease ushered in by definite paresis or paralysis of a limb or set of muscles alone and in no instance was paresis or paralysis the dominant clinical feature. The virus of the Australian disease has been conveyed to thirteen sheep, a calf and a yearling foal. A histologic examination of the brains of these animals has shown the same pronounced perivenous cellular infiltration as was seen in the human cases and in monkeys.

Bone Growths Around Joints in Paraplegia.—Mme. Dejerine and Ceillier call attention to the resemblance between the hypertrophic type of tabetic joint affections and the joint affections with paraplegia from injury of the spinal cord. They found these *para-ostéo-arthropathies des paraplégiques* in 48.7 per cent. of seventy-eight cases of paralysis of the lower extremities, all but one from war wounds of the spinal cord. Their thirty-two illustrations and two other plates explain the trouble as the result of local edema, lowering the vitality of the connective tissue, in connection with the functional irritability of the intermediate grey column under the influence of toxic products. There is isolated bone production; the osteophytes lie separate from the skeletal bones, and these bones and the joint retain their normal outlines. Evidently various spinal diseases, syphilitic myelitis (as in one of their cases), tuberculous meningomyelitis, myelopathic muscular atrophy, and syringomyelia, as well as tabes, are liable to be complicated by development of these osteophytes. No inflammatory symptoms accompany them. They may develop around more than one joint, and the movements of the joint are not impaired. The men whose paraplegia was improving and who were able to use their legs more or less, never developed these osteophytes. If the paralytics with osteophytes were able to walk about, there might be fractures, etc., as with tabetic joint disease.

Gastric Fever.—Etienne relates that a fever of short duration with mild gastro-intestinal derangement, what he calls *embarras gastriques fébriles*, was comparatively common in the advanced infirmary in his charge. This febricula has been ascribed to indigestion, chilling, etc., but in seven typical cases he was able to cultivate typhoid or paratyphoid bacilli from the blood during a relapse. Agglutination was at 1:50 or 1:20. In other cases, other microbes were responsible. He only encountered one case in which the colon bacillus could be cultivated from the blood. This typhoidal gastric fever is not an attenuated form of typhoid fever; it is distinguished from the latter by the usual sudden onset, the lack of rose spots, and even of much depression and of diarrhea. It is an attenuated gastro-intestinal infection with a brief phase of septicemia, but liable to relapses and recurrences. Whatever the germ involved, this gastric fever or febricula ranks with catarrhal jaundice and toxi-infectious gastroenteritis.

*Serodiagnosis of Inherited Syphilis. H. Barbier.—p. 169.
Typhoid in Infants. J. Crespin and B. Saracino.—p. 183.

Serodiagnosis of Inherited Syphilis.—Barbier has been making a special study of atrophy in nurslings during the last fifteen years, and reports a positive Bordet-Wassermann reaction in 33 per cent. of ninety-three infants with atrophy. A number of others were certainly syphilitic, so that the proportion was at least 42 per cent. In 11 per cent. there was an unmistakable tuberculous taint. Atrophy from improper or inadequate feeding can be effectually combated by regulating the diet, but these inherited taints call for specific treatment besides. Some of the infants begin to thrive when mercury is given; others are unable to bear it. In any event, he warns that it should be given very cautiously, in minimal doses.

Obstetrical Practices in Armenia. Ketenetjian.—p. 316.
Chimpanzee Born in Captivity, in Cuba. L. Montané.—p. 323.

Double Solid Rudimentary Uterus.—Gammeltoft operated in the two cases he reports, and compares them with seven similar cases he has found in the literature. In three other cases on record the deformity was unilateral. In all but one of the total cases the women complained of abdominal pains at monthly intervals. The idea that the pains in these cases originated in the uterus is of recent date. Formerly the operation was done on the ovaries, but in the later cases the uterus was removed, leaving the ovaries if they seemed to be sound, and this is the logical and safest treatment.

Operative Treatment of Genital Prolapse.—Mercadé presents arguments to prove that the first degrees of genital prolapse are due to muscular degeneration of the anterior segments of the levator ani muscles. Hence treatment must be directed to overcome the effects of this degeneration. This can be done by suturing the two muscles together on the median line, leaving only room enough for the passage of the urethra. All his patients treated by this technic have been permanently cured. He cannot understand why others address their operative measures to the region at the back of the vagina, when the sagging of the bladder is always the first step in genital prolapse. He cuts out a large lozenge-shaped piece in the anterior wall of the vagina, and separates the bladder from the vagina and uterus, working with bistoury and fingers along the natural lines of cleavage. He does not tampon the vagina nor constipate the woman, but purges the third day, removing the threads the tenth day. Even a retention catheter was not needed in his cases, but he used the catheter the same evening and again the next day if necessary. In one case with an elongated cervix, 8 cm. long, he corrected the prolapse before amputating the cervix. Even if the uterus should have to be removed on account of the prolapse, he still would complete the operation with this suturing together of the levator muscles.

Compulsory Notification of Tuberculosis.—Summarized in Paris Letter, p. 1173.

Respiratory Insufficiency of the Apex.—Merklen and Chuiton warn that the diameters of the heart ventricles should be recorded as well as the lung findings in dubious cases. Moderate hypertrophy of a ventricle may reduce the respiratory capacity of the apex, and explain certain cases with dyspnea and pain in the chest after exertion, with lassitude and modified vesicular murmur. Examined from the rear, the findings are modified or disappear altogether.

Tubercle Bacilli and Acid-Resisting Oospora.—Sartory cultivated from the sputum or urine an acid-resisting oospora which deceptively simulated tubercle bacilli on fragmentation.

Accidental Decline in Blood Pressure with Permanent Hypertension.—Vaquez cites some instances of a temporary or permanent drop in the blood pressure with permanently high tension. The findings then are misleading if the previous state of the tension is not known. Typhoid fever, pneumonia and influenza often reduce the blood pressure. In one case of pneumonia the pressure fell from 240 to 160 mm. and never returned quite to its former figure. In the course of fulminating cerebral hemorrhage in one case the pressure dropped from 270 to 160 mm. Study of such cases apparently demonstrates that the hypertension is primary and independent, at least at first, of any organic lesion. It seems to be due to some functional disturbance in organs which regulate arterial pressure. The diseases which are most readily accompanied by a drop in blood pressure are the ones in which suprarenal insufficiency is common.

Uneven Pupils in Syphilitics.—Sergent warns that a pleuritic process at the apex is liable to modify the pupil in syphilitics.

The Leukocytes in Influenza.—Lion and Crétin examined the blood in nineteen cases of influenza at the height of the October-November epidemic, and found a constant myelocythemia. This seemed to be the consequence of a primary localization of the agent causing the disease; it was found in the mild as well as the severe cases.

Conditions at Lille During the German Occupation.—Lemoine passed through the German occupation of Lille and was impressed by the modifications of the medical pathology of the region. Tuberculosis became very prevalent, and in 1917 there was an actual epidemic of glandular tuberculosis, mostly of the neck, but the sternum and ribs soon became involved, and tuberculous peritonitis became very prevalent. Lemoine is inclined to ascribe this epidemic of different forms of tuberculosis to the lack of mineral salts in the food, the deprivation of green vegetables and the poor quality of the scanty food in general. Scurvy prevailed at times, but the food commission succeeded in arresting it by obtaining lemons from Holland which were placed freely at the disposal of the populace. There were numerous cases also of peripheral neuritis, and cases of pellagra also developed. There were also two waves of dysentery, but no antidysentery serum was available; the Germans finally supplied a small amount. Every one lost weight during the German occupation; the loss of 20 to 25 kg. was the regular thing in adults. Nine tenths of the inhabitants did not eat any meat for two and a half years. The American food commission saved the population of the occupied region from completely disappearing, and they did all they could, with indefatigable zeal, to give the hungry people all in their power in the way of food, but their efforts, he says, were always *contrariés* by the German authority. The municipality also maintained a committee which bought in Holland all the Germans would allow it to buy. The efforts of the two commissions were unable to provide ever more than 1,450 calories for the average daily ration, according to scientific estimates.

Meningococcus Carriers.—Stévenin relates that in making 652 examinations for carriers in a meningitis environment, 11 per cent. of the men were found to be carriers. Also 12 per cent. carriers were found in 2,844 examinations in environments quite free from meningitis, and 7 per cent. in 333 examinations of groups of about twenty men from scattered environments. Not one of the healthy carriers was known to have transmitted the disease although they were kept under supervision for months.

Atrophy, etc., of the Muscles with Sciatica.—Chiray and Roger refer to the atrophy, the exaggeration of the idiomuscular contraction and the electric contractility which are liable to be encountered with sciatica. This *syndrome musculaire de la sciatique* is extremely variable, which is remarkable when we consider the uniformity of the sensory disturbance. This indicates that the seat of the mischief is at the point where the the motor and sensory fibers run separate, that is, at the roots. It has been found further that in more than half the cases the cerebrospinal fluid has a high albumin content, with lymphocytosis and sometimes a positive Wassermann reaction. All this testifies to some inflammatory reaction in the meninges preceding or following the inflammation of the roots, as the cause of sciatica in the majority of cases. The muscular anomalies form an integrant part of sciatic neuritis and sciatic neuralgia, which differ only in degree.

Fatalities from Arsphenamin.—Bory reports a case of typical arsenical eclampsia developing the fourth day after the fourth injection of French arsphenamin, with an epileptiform attack, coma with mydriasis, stertor and death. Two similar cases have occurred recently at the center at Troyes in the last six months, and he cites ten other fatalities of the same nature which he has found recorded in recent reports from different centers.

Sudden Death in Football.—The only pathologic finding at necropsy was dilatation of the macroscopically sound heart, and the large thymus. The man of 22 fell suddenly stricken, like the Marathon runner.

*Dulness in the Axilla with Disease in the Pleura. G. Mouriquand. —p. 149.
*Chronic Intestinal Stasis. V. Pauchet.—p. 151.
Recent Experimental Research on Lymphocytosis and the Roentgen Rays in connection with Cancer. J. Luzoir.—p. 152.
Abortive Phenol Treatment of Furuncles. A. L. Soresi.—p. 154.

Dulness in the Axilla.—Mouriquand gives illustrations to show the characteristic information to be derived from percussion and auscultation of the axilla in pleurisy and pneumonia as well as in chronic processes in pleura or lungs. In over a thousand cases examined, when there was accompanying posterior dulness in the chest, dulness in the axilla in at least 75 per cent. of the acute and subacute cases was explained by the presence of an effusion. When the dulness was below the axilla, this was the finding in about 50 per cent. of the cases. Dulness in or just below the axilla should therefore turn the scale in favor of exploratory puncture, thus permitting an early cure.

Pathogenesis of Chronic Intestinal Stasis.—Pauchet refers to Arbuthnot Lane's clinical picture of chronic stasis. He declares that the roentgen and operative findings in such cases show that it can be explained by physiologic and mechanical factors, alone or together. The vicious functioning probably precedes the kinks or partial strangulation, and in the functional cases, without permanent constricting bands, it may be possible to correct conditions by physical culture, massage, the rational use of purgatives and possibly organotherapy, although he asks parenthetically "Which?" When the intestine has had to be short circuited, the results to date have been very encouraging. In conclusion Pauchet warns that we must not be in too much of a hurry to diagnose chronic appendicitis, adnexitis or gallbladder mischief, enteritis, latent tuberculosis or neurasthenia when confronted with a case of general autointoxication or dyspeptic or other abdominal phenomena. We should examine the patient with the roentgen rays every twelve or twenty-four hours until the bismuth suspension has passed entirely out of the small intestine, the cecum, the colons and the rectum. Any delay in the passage of the feces should be carefully noted. One radioscopy is not enough; three or four radioscopic examinations are necessary to diagnose correctly chronic intestinal stasis.

*Lamblia Enteritis. M. Labbé.—p. 161.
Parallel Between Puerperal and Surgical Infections. V. Wallich.— p. 162.
*Exophthalmic Goiter and Ovarian Insufficiency. A. Tilmant.—p. 164.

Lambliosis.—Labbé reports experiences which confirm that the lamblia is capable of inducing grave and rebellious intestinal disturbances. The chronic enterocolitis is not in itself very severe, but the general health suffers profoundly and tuberculosis may be suspected. The onset is usually insidious, and the lambliosis is harder to cure than amebiasis. Emetin, arsphenamin, none of the drugs tried displayed any efficacy.

Exophthalmic Goiter and Ovarian Insufficiency.—Tilmant describes a family in which of the 17 members, 57 per cent. of the 7 men and 70 per cent. of the 10 women have goiters. In 6 of the women symptoms of exophthalmic goiter developed as the menopause became installed or the ovaries became insufficient from other cause. In all of the women the goiter subsided temporarily during their pregnancies. One of the sons, who had a goiter, married his cousin who already showed signs of hyperthyroidism, and their three daughters have developed exophthalmic goiter but their three sons seem to be sound.

*Cesarean Section for Hemorrhage. K. Brunner.—p. 321.
*Epilepsy. M. Tramer.—p. 328. Conc'n.

Cesarean Section for Hemorrhage from Vaginal Varices.—Brunner cites statistics which show that hemorrhage from varices in the vagina very often proves fatal: 13 deaths in Wullmer's 15 cases during the pregnancy; 7 in 16 during parturition; Delahousse's compilation of 11 deaths in 30 cases, and Guerdjikoff's 2 deaths in 3 cases. Brunet in a case of bleeding from multiple varices was able to arrest the bleeding by tamponing, but the moment the pressure was removed the blood spurted anew from several points. He delivered the woman by abdominal cesarean section and the varices collapsed by the third day. Brunner reports here a case that resembled this only that the profuse and persistent bleeding came on during delivery, which was impeded by the large size of the child, 4,900 gm. The labia were so edematous and swollen that the ligatures applied pulled out, and the hemorrhage was controlled only by numerous clamps filling the vagina. The woman recovered after abdominal cesarean section and antistreptococcus serotherapy.

Epilepsy.—Tramer compares the clinical course with the necropsy findings in fifty epileptics, expatiating on the anatomic changes in the brain which suggest an explanation for the seizures. He thinks that the marginal gliosis (*Randgliose*) so often encountered comes under this heading, but only when there is another factor superposed, namely, pathologically increased pressure on the brain of longer or shorter duration. Hence the necessity for combating the seizures to ward off the consequent stimulation to further production of the gliosis. In some of the epileptics marked changes were found in the Betz' cells in the central convolution, and the clinical course in these cases had been more of a spastic paresis type. Other anatomic findings seemed to correspond to the cases of a myoclonus or paramyoclonus type. The prognosis with epilepsy depends on whether the psychic or psychopathologic condition is secondary to the epilepsy or merely combined with it. Epileptic secondary dementia is characterized by impairment of the memory, retarding of mental and physical processes of association, and intense emotional instability.

March 22, 1919, **49**, No. 12

*Hernia in Appendicectomy Scar. P. F. Nigst.—p. 353.
*Chenopodium Poisoning. P. Ryhiner.—p. 360.
*Otitis in Influenza. Farner.—p. 365.

Hernia in Appendicectomy Scar.—Nigst had hernia develop in fourteen of 117 drained appendicectomies. The tendency to hernia seems to be less with the McBurney technic and when the lips of the wound were sutured with absorbable material in tiers, close up to the drain tube. He warns expressly against parallel incisions, which are necessary when the incision is too close to Poupart's ligament. In dubious cases it is better to drain than not, as these cases heal with less tendency to hernia.

Chenopodium Poisoning.—Ryhiner reports three cases of serious chenopodium poisoning encountered in the last three years, two of them terminating fatally. The patients were children between 2 and 7; the one that recovered was a girl of 2½. This latter child was given 5 drops of chenopodium oil three times, with an hour interval and, two hours after the last dose, a tablespoonful of castor oil. The whole was repeated the second day, and sixteen ascarides were passed within four days. As the child still complained of abdominal pain, the vermifuge was given again a week later; two doses of 8 drops with two tablespoonfuls of castor oil were given on two following days. Three days later the symptoms of severe poisoning developed suddenly and it was over a week before the child recovered. In one of the fatal cases the dose had been three times 10 drops of chenopodium oil with one hour interval, followed by not quite 1 gm. castor oil. The child vomited an hour later. The next day the course was repeated but there was no stool or urine and the child died the following morning. The third case was the druggist's mistake, 5 gm. doses being dispensed instead of the 5 drops ordered. Ryhiner emphasizes that chenopodium oil is an excellent vermifuge but the doses usually given are needlessly high. His own practice is to give two doses of as many drops as the child is years old, with an hour interval, following in two hours with a purge. If this does not work in two hours he repeats the purge. Vigorous purging is indispensable. The manifestations of the poisoning are somnolency, passing into profound coma, clonic convulsions and facial paralysis on one side, screaming, horizontal nystagmus, loss of reflex action, and death from arrest of respiration.

Otitis in Influenza.—Farner reports 115 cases of influenza otitis. They formed about 3.5 per cent. of the cases of influenza at one emergency hospital at Zurich.

Vaccination Against Typhus.—Otto has been testing a vaccine against typhus since April, 1917, and has vaccinated 750 persons. The vaccine was prepared from the blood of typhus patients at the height of the disease or early in convalescence. It seemed to be perfectly harmless but did not protect against the infection. However, the disease ran a decidedly milder course in the vaccinated than in others.

Malaria.—Among the lessons learned from the war experiences, Mayer remarks, is that the normal incubation period with malaria is ten or twelve days, but it may be much longer. He has seen it up to a year and a half. Malaria is a chronic disease with a tendency to relapses under any treatment. In some years, however, it seems to become spontaneously extinct but otherwise lasts one, two or three years. As a rule, 1 gm. may be accepted as the minimal daily dose. The prolonged use of quinin may induce symptoms of toxic action, eruptions, eczema and diffuse edema, sometimes with hemorrhages in skin and mucosa and even severe intestinal hemorrhage. Blackwater fever is still a mystery; in one case it was brought on by roentgen exposures of the spleen. Provocative procedures interfere with the self-healing processes, he says, and should be restricted to latent cases. As anopheles abound in Germany, infection has already occurred at numerous points and it is important to have the men with a history of malaria kept under supervision in their home towns.

Urobilinogen in Differential Diagnosis.—Scholz regards the amount of urobilinogen in stools and urine as an index of the destruction of the blood that is going on. It can be determined by the colorimeter or by a spectrophotometric technic. Salomon and Charmass have recently asserted that with pernicious anemia the content of urobilinogen in the stools is two or three times the normal amount, while with gastritis, gastric or bowel cancer the content is only a half or a third of the normal figure. Scholz found in thirteen gastric cancer cases that in eleven the content was materially reduced, confirming their statements, but in the two other cases the findings were conflicting. The findings in his three cases of pernicious anemia were also conflicting. The urine findings also proved undependable, even with metastasis in the liver.

Nutritional Disturbances in the Myocardium.—Büdingen recalls that experiments on the surviving heart have shown that sugar in the blood is the main nutriment and source of energy for the heart muscle. His own research has demonstrated further that a deficit in the blood sugar is liable to entail serious disturbance in the growth and actual functioning of the myocardium, a hypoglycemic cardiodystrophy. This result of absolute or relative hypoglycemia may accompany heart disease. The clinical manifestations are a sensation of oppression or pain in the heart region, with or without radiating pains, these disturbances coming on with or increased by exercise, the only objective findings being sometimes faint sounds at the base. In the elderly it is impossible to distinguish the findings with hypoglycemia from coronary sclerosis. The blood sugar content threw light on three otherwise inexplicable cases of sudden death with heart of normal size, the patients' complaints having been ascribed to hysteria or neurasthenia by the physician. When digitalis acts effectually, this hypoglycemic cardiodystrophy can be excluded. But when the usual remedies fail, and the sugar content of the blood has dropped low and disturbances are noted while the sounds at the base grow fainter, then the system is clamoring for grape sugar, and when this is supplied, all returns to normal once more. Sugar given by the mouth is not reliable for the purpose; he infuses a highly concentrated solution of grape sugar, requiring the patient in serious cases to stay in bed. He never attempts the infusion in the office or home. In his over 5,000 infusions by the vein he has never seen any lasting harm result, while his observation of the results has convinced him that we might be able by this measure, taken in time, to overcome or ward off toxic-infectious injury of the heart. Of course coronary sclerosis is irreparable, but the fatal termination is generally due to intercurrent functional factors, and these we may be able to keep under control by therapeutic action on the disturbed internal workings of the heart. In hundreds of cases, he has witnessed permanent benefit, essential improvement in the general physical capacity and in the heart capacity, with relief from disturbances and from the need of drugs, even in advanced cases of coronary sclerosis, with this hypoglycemic cardiodystrophy. Even without this latter, convalescents from infectious diseases with extrasystoles, etc., benefited by the sugar treatment. He usually begins with a 10 per cent. solution and increases the concentration as he proceeds, and gives two or at most three infusions during the week, except in pneumonia or septic fever when a daily infusion may be called for. He usually infuses about 200 c.c. of a 10 or 20 per cent. solution of grape sugar. Bang has demonstrated that 90 or 95 per cent. of the infused sugar vanishes almost instantaneously from the circulation; it is evidently taken up greedily at once by the heart, liver and muscles. Büdingen has been preaching this "sugar treatment" of the heart since 1913 as The Journal mentioned then.

Biologic Treatment of Ozena.—Wittmaack ascribes ozena to the lack of the normal ciliary movements which have been lost by some inflammatory process and consequently the physiologic cleansing mechanism has been destroyed. To remedy this, he diverted the outlet of the parotid gland into the maxillary sinus so that the saliva passed from this sinus into the nose, thus laving the nasal mucosa constantly. As soon as this occurs, the ozena begins to subside without any other treatment and is soon completely cured. The operation begins with the Caldwell-Luc radical operation on the maxillary sinus, and with bilateral ozena has to be done on both sides. In his latest case he did it all at one sitting under local anesthesia. The interval since in his first case is now eight months, and the cure has been complete and permanent. The drawback to the method is that during chewing the flow of saliva is so profuse that some may drip from the nose. The patient has to choose between this and his ozena, and all his five patients have been more than satisfied with the outcome, especially as the secretion of saliva seems to grow less with time. The ozena in each case had resisted all kinds of treatment for years.

Tuberculin in Diagnosis.—Bergmann argues that it is possible with the tuberculin test to distinguish between inactive tuberculosis which is on the point of flaring up and tuberculosis which is slumbering. For example, a man with indecisive lung findings has slight fever. If the titrated skin tuberculin reaction is positive, then he had better be kept under close observation. If it is negative, then the fever must be due to other causes.

The So-Called Rheumatic Iritis.—Folman regards it as significant that in 47 per cent. of his ninety-three cases of supposed rheumatic iritis, there was a history of gonorrhea, and probably the proportion was still higher in reality. This suggests possible advantage from antigonococcus vaccine in treatment of severe and recurring cases of iritis.

The Medical Profession in the Service of the State.—Kollwitz is a "sozialdemokrat" and this address was delivered at a meeting of the Verein sozialdemokratischer Aerzte at Berlin. He comments on the anomalous position of physicians in our present civilization, saying "This anomalous position has been a brake on the wheels of progress of social hygiene. An actual universal hygienization of a people requires as its first prerequisite that the practice of medicine should become a state service." His plan is that physicians are to be given the choice of private practice or of entering the service of the state. The state physicians would have the eight hour day, and an office building would be supplied by the state, like the postoffice and school buildings, where physicians and specialists would serve in turn in three day and night shifts, with provision for bedside calls. . . . "The confidence which the sick man feels in his special physician would soon come to include the entire unit in the community office building, when he found that he was being cured." Schwalbe comments on this, as follows: "Sozialdemokratie is supposed to be the most radical champion of freedom, but in reality it is exactly the reverse. In no other political system would the individuality be so restricted, and initiative so crushed out. With the physician serving only an eight hour day, if a patient seen early in the day grew worse toward night, he would have to have another physician call on him. The state employed physician would have no independence; once embarked on this current he could not go back." Kollwitz expressed his conviction that a socialistic society would treat the medical profession with more consideration and justice than it has been accorded hitherto, but Schwalbe comments that experiences with the sickness insurance societies, which are sozialdemokratisch, show that exactly the reverse may be anticipated.

Injury of Esophagus in Child of Four. F. Bonhoff.—p. 102.
*Roentgen Treatment of Jacksonian Epilepsy. O. Strauss.—p. 103.

Sinusitis with Influenza.—Fraenkel remarks that the publications on the brief wave of influenza in July and the furious flood in October and November all coincide in the main particulars, but he has not happened to see any account of sinusitis. Among 400 influenza cadavers, he sought in sixty for evidences of disease in the accessory nasal cavities, and in these sixty cadavers the sinuses were found pathologic in 75 per cent. He does not know of any other acute infectious disease that involves the sinuses to such an extent. In 146 other cadavers he found evidences of sinusitis in less than 50 per cent.

Acute Nephritis Without Albuminuria.—Davidsohn describes in detail three cases in which a focal glomerular nephritis was accompanied by quantities of formed elements in the urine but no or slight and transient albuminuria. Oliguria was constant but never very pronounced. In two of his cases hematuria for three or four days was the first symptom, and one patient had colic-like pains. As every acute nephritis may run into a chronic form unless it gets proper treatment, the importance is obvious of not overlooking the nephritis in cases of this kind without albuminuria.

Radiotherapy in Epilepsy.—Strauss reported in 1913 that he had succeeded in improving conditions in epileptics by roentgen exposures. The war interrupted this work, but he has recently resumed it, and now reports a remarkable case of improvement under this treatment. The young woman had had severe epileptic seizures on the right side and both sides of the face, with frequent loss of consciousness, since the age of 3. At 11, the cramp center for the right arm was excised. After this the arm was paralyzed but the seizures were milder and less frequent for a time. At 22 she was having seizures daily, and Strauss applied four erythem doses of hard filtered roentgen rays in four sittings at four weeks' intervals. The region exposed was the left fissure of Rolando. Since then the girl has had no severe seizures, merely occasional slight clonic contractions which are growing less frequent. Strauss believes that the removal of the cramp center was the actual cause of the improvement, but the operation had to be reinforced with the roentgen rays before its full effect could be realized. He adds that his success in this case justifies experiments in this line with epilepsy following war wounds of the skull.

*Transmission of Smallpox to Fetus. S. Cappellani.—p. 193.
*Congenital Osteosclerosis. G. Di Giorgio.—p. 198.
Study of the Fats in the Stools of Twenty-Three Infants. L. Maccone.—p. 202.

Transmission of Smallpox to Fetus.—Cappellani reports four cases in which the new-born infant developed smallpox showing that it had evidently been infected before birth, while the mother was merely in the phase of incubation. The infants seemed normal at birth, but developed the symptoms of smallpox in five or six days. In another case the mother was healthy but the infant showed fever twenty-four hours after birth, and the next day unmistakable signs of smallpox followed. The mother was revaccinated at once and gave a typical response but showed no signs of smallpox at any time, although smallpox was known in the quarter at the time.

Congenital Osteosclerosis.—Di Giorgio gives illustrations of a girl of 6 and brother of 3 who both present complete ankylosis of both elbows, flexed at a right angle. The father is a man of 70, the paternal uncle of the wife, who was only 15. The Wassermann reaction in mother and children is negative. The deformity is evidently the result of symmetrical chondrodystrophy.

*Albumin in Cerebrospinal Fluid. A. Prunell.—p. 660.
*Protozoa in Fresh Waters in Uruguay. E. H. Cordero.—p. 668.

Intestinal Trichomonosis.—Escomel's research has confirmed that the trichomonas forms cysts, and that it is liable to induce processes in the liver like amebic hepatitis. Intestinal trichomonosis may assume the form of simple diarrhea or dysentery or both, or a choleriform disease. It may be acute or chronic from the start, or chronic with intermittent acute forms. It may induce inflammation and ulceration from the rectum onward, decreasing in intensity upward. Microscopic examination of fresh feces disclosing the trichomonas may reveal other helminths which should also be expelled. Infection occurs by flies or other insects or from water, possibly from water used on vegetables and fruits. He says that since he demonstrated in 1910 the destructive action in vitro of turpentine on the trichomonas, and applied it in clinical cases, trichomonosis has become an easily curable affection. Under turpentine treatment, he has seen dysentery, intractable for months, subside promptly in two weeks, while three days completed the cure in the recent cases. The urine should be inspected to detect any tendency to drug nephritis. Even if this develops, it is mild and transient, and is extremely rare in the absence of a special predisposition. He starts with a course of iodin treatment. Each night the patient takes an enema of a liter of decoction of krameria or plain boiled water, expelling it at once. Then a second enema is given of 1 liter of spring water in which is dissolved 1 gm. of sublimed iodin, and this enema is also expelled at once. The enema should be given with the patient reclining in bed, lying on the left side. There is some discomfort from the iodin enema but this soon subsides; it can be relieved by hot applications to the abdomen and anus, or a small enema with some sedative may be given and retained. The iodin enema is usually borne well; it is never so painful as a silver nitrate enema. The food should be milk and carbohydrates or the latter exclusively, drinking copiously of rice water, decoctions of acacia and of linseed. Hot applications should be made to the abdomen every two, three or four hours. Repose is useful. The results have been notable in his extensive experience. If any trichomonas are still found in the stools by the fourth day, this indicates that the protozoa have invaded very high regions or are ensconced deep. In this case he institutes a course of turpentine by the mouth or in enemas, alternating the three procedures until the trichomonas and their cysts have completely disappeared. Escomel gives the illustrated history of the biology of the trichomonas and reviews what has been written on the subject by others, with details of the turpentine technic.

Coronary Embolism in Heart Disease.—Lutembacher describes a variety of infectious endocarditis in which the cardiac thrombi are made up almost exclusively of leukocytes, with very little fibrin. As they contain few microbes, they do not induce an inflammatory reaction, but in the skin they may determine a purpuric eruption. His sixteen illustrations are from a case in which the roentgen findings during life were compared with the necropsy findings, an infectious endocarditis having become superposed on an old mitral stenosis.

Iodized Vaccine in Typhoid in Children.—Morquio and Zerbino report disappointing results in treatment of seventy-seven children treated with iodized vaccine made by Ranque and Senez' technic. The vaccine seemed harmless, but no benefit from it was observed.

The Suprarenals in Typhoid.—Nuñez remarks that the suprarenals are involved in typhoid both early and constantly, as a rule. This is the cause of the hyposthenia, the hypotension, the hypocholesterolemia, the dicrotic pulse and the dissociation between the pulse and the temperature. He makes a point of daily subcutaneous injection of epinephrin in every case of typhoid in which one or more of these five symptoms are observed.

Partitioned Off Otitis Media.—Regules' illustrations show that, instead of being general, the inflammatory process may be restricted to some one point in the middle ear, where the pus is walled in. In puncturing, if the needle does not happen to hit this point, the puncture may not give any relief, and this possibility should be borne in mind when relief does not follow promptly on paracentesis. He reports two cases.

Quantitative Test for Albumin in Cerebrospinal Fluid.—Prunell's diaphanometric method was described in these columns, April 19, 1919, p. 1196.

The Protozoa of Uruguay.—Cordero describes, with four plates, fifty varieties of ciliated protozoa found in the fresh waters of Uruguay.

*The Hormones and the Vegetative Nervous System. O. Gallotti.—p. 3.
*Metameric Abnormal Contraction and Relaxation. C. C. Da Costa.—p. 10.
Kaolin in Treatment of Cholera. W. Almeida.—p. 23.

The Hormones and the Vegetative Nervous System.—Gallotti argues that the harmonious action of the involuntary organs is due in large part to the hormones influencing the autonomous and the sympathetic nervous system. He reviews the action of the different endocrine glands in turn, saying that the relations between the hormones and the vegetative system must be studied before we can prescribe organotherapy intelligently.

Metameric Dysthenia.—Da Costa discusses the abnormal conditions in regard to contraction or relaxation which are liable to be observed in certain organs belonging to the same metamere. Spasm of the esophagus, of the glottis, and of the vagina displays this metameric character. The uterus can also present circular constriction at any height.

*Beriberi. C. Fraga.—p. 65. Commenced in No. 7, p. 49.
*Regional Anesthesia. J. de Mendonça.—p. 68. Cont'd in No. 7, p. 52.

Deficiency Disease and Beriberi.—Fraga gives the history of the research on beriberi in different countries, and reports some personal research at Bahia. Nine convicts in solitary confinement consented to a dietary experiment and were fed with polished rice or polished plus sterilized rice or sterilized beans. The penitentiary in question has had beriberi endemic in some years and not in others, although the diet is constantly the same. The nine convicts acquired a distaste for this sterilized diet, and it induced digestive disturbances so that the experiment had to be suspended by the thirty-sixth to the thirty-eighth day. No nervous symptoms developed in any of them. Another series of experiments is now under way with another group of convicts in the penitentiary who have been promised pardons if they hold out. They are now at the forty-third day, but still *no nervous symptoms are apparent in any of them.* The experiments with fowls reproduced typical polyneuritis gallinarum. In Brazil, both Allen M. Walcott (The Journal, Dec. 18, 1915, p. 2145) and A. de Assis found it easy to induce this deficiency disease in fowls. Assis induced it with two cereals not previously experimented with elsewhere, namely, the bean *Phaseolus vulgaris* and mandioca, *Manihot utilissima.* Fraga's conclusions are that polyneuritis gallinarum and beriberi in man are quite distinct morbid entities. The cerebellar symptoms in particular distinguish the former exclusively, and this alone would invalidate the generalization of the conclusions from this disease to man. In man, he declares, the dietary deficiency acts merely as a predisposing cause for human beriberi.

Regional Anesthesia.—De Mendonça traces the history of regional anesthesia from the days of myths to the present time, reviewing the various efforts made to induce the deepest analgesia with the minimum of the anesthetic. His conclusions from this analysis and his own experiences with 1,500 operations done under regional anesthesia, emphasize that regional anesthesia, done with procain (novocain) associated with epinephrin, is the greatest progress realized in surgery since the advent of aseptic surgery. Local anesthesia or blocking the trunk nerve, alone or together, suffice for all surgical operations except abdominal operations which require separation of inflammatory adhesions or much manipulation of viscera. To date there has been no fatality attributable to them. Even in the exceptional cases in which they do not suffice, they can be applied advantageously in combination with general anesthesia. For intractable children or very nervous adults it is better to resort at once to general anesthesia. Local anesthesia, with or without blocking the trunk nerve, should always be the preference in all cases of shock, extreme inanition, or with grave lesions of kidneys, liver or lungs.

*The Prevailing Epizootic. R. Kraus.—p. 256.
Phenomena Observed when Roentgen Rays Are Passed Through Openings of Special Sizes and Shapes. J. Laub.—p. 256.
*Heliotherapy in Chronic Nephritis. A. Cetrángolo.—p. 257.

Combined Action of Serum and Leukocytes in Experimental Peritonitis.—Bachmann injected antityphoid serum plus leukocytes into the guinea-pig peritoneum and found that, in certain proportions, this mixture seemed to protect the animal against an otherwise pathogenic inoculation of typhoid cultures. There seemed to be an optional curve for the proportions, above and below which there was no protective action.

Starch Dystrophy.—In Navarro's case the 5 months' infant had been fed inadequately and exclusively with cereal gruels. It had not lost much in weight but was much debilitated and had developed a necrotic abscess on the shoulder. This yielded to potassium permanganate at 0.5 per thousand, applied three times a day. The child was fed with breast milk for four days, then skimmed milk and whole milk, and rapidly recuperated.

Epizootic Meningitis.—Kraus relates that last year and again this year there has been an "enzootic meningo-encephalitis" prevailing among horses in Argentina. Nothing pathologic could be found in the organs of the horses, but rabbits injected with emulsions of the brains died with symptoms resembling those of rabies. The brains of the rabbits showed no macroscopic lesions, but proved as virulent for other rabbits as the original emulsion. The passages from the rabbit exclude the assumption of poisoning from food. A gram-negative diplococcus was cultivated from the horse brains. See also Buenos Aires Letter, p. 1309.

Heliotherapy in Chronic Nephritis.—Cetrángolo gives the tracings from two cases of chronic nephritis showing losses of weight from 300 to 1,200 gm. under the influence of heliotherapy, while the peripheral vasodilation relieved the heart of a portion of its work. The minimal arterial tension also declined.

January, 1919, 2, No. 7

*Operative Treatment for Gallstones. E. Ribas y Ribas.—p. 1.

Operative Indications with Gallstones.—In Ribas' 116 operative cases of gallstones, fully 50 per cent. never had actual gallstone colic. The diagnosis in many cases was based merely on vague, indefinite sensations, but starting in the subhepatic region. The gallstone itself, as a simple foreign body, never interests the surgeon, merely the consequences from its presence. The clinician likewise is not interested in the expulsion of the stone, but in the condition left afterward. If the gallstone proves to be round and composed of cholesterin, this is an aseptic concretion, and may be assumed to have done little if any damage. The discovery of diverticuli in the walls of the gallbladder has confirmed the general assumption that infection once installed is difficult to dislodge—an additional reason for cholecystectomy. This removes the organ which is the source of gallstone production while the infection responsible for the development of the gallstones has rendered it functionally useless. The horse, the ass and certain other animals have no gallbladder, and experimental research and the clinic confirm that this organ is not necessary to life. In his 27 cases of simple cholecystectomy, one patient with a hydatid cyst in the liver succumbed to pneumonia; the others all recovered; 13 died in the 70 cases with drainage of the hepatic duct. In 10 of these cases the progressive course of the inflammatory process around was responsible for the fatal outcome.

Ribas' experience teaches also that, as a rule, the danger is greater with an extremely acute cholecystitis developing for the first time than with an equally acute flaring up of a chronic cholecystitis. With the latter the walls are thicker and there is less danger of perforation. The form with typhoid is distinguished by the rapid enlargement of the gallbladder accompanied by high fever and local pain. All this may retrogress spontaneously, but if the toxic action is pronounced and it keeps up for several days, in typhoid or paratyphoid, he advises cholecystectomy. He does not approve of palliative operations except for certain rare indications. He gives an illustration of a case in which acute cholecystitis during convalescence from paratyphoid developed fatal perforation under expectant treatment, and describes seventeen different types of chronic gallbladder disease, illustrating specimens, with two colored plates. In one case the liver was completely wrapped around the gallbladder as far as the cystic duct, and adherent.

He has operated in ten cases of subphrenic abscess traceable to gallstones. There is generally a secondary pleuritic effusion just above in such cases and this may mislead the diagnosis. In one case puncture was negative until the needle was inserted on the posterior axillary line, between the fifth and sixth ribs, which opened up a large extraperitoneal abscess between the diaphragm and the rear of the convex surface of the liver. A complete cure was not realized, however, until the gallbladder was removed five months later. There were evidences of pancreatitis in 42 of Ribas' 116 cases, and there was a history of gallstones in 5 of his 12 operative cases of hemorrhagic pancreatitis. He regards cholecystectomy as the surest means to cure pancreas mischief with gallstones. He has had 3 cases of cancer of the gallblader and a stone was found in this organ in one of them.

*Specific Phagocytosis in the Immunized. A. Bachmann.—p. 1.
*Epicondylalgia. J. M. Maidágan.—p. 24.
*Mastoiditis in Infants. M. Steinsleger—p. 29.

Phagocytes in Immunity.—Bachmann is professor of bacteriology at the University of Buenos Aires, and he states: "The series of experiences here described have demonstrated for the first time the presence of some special substance in the leukocytes of immunized animals. The presence of this substance renders these leukocytes better fitted than others to contend with the infection. This *anticuerpo leucocitario* is found only in small amounts in the leukocytes. This is explained by the assumption that, being an element of living cells, it is reproduced in proportion as it is used up. The existence of this substance throws light on certain phenomena which have been hitherto obscure." He analyzes these phenomena in detail, adding "The antibodies and the serum, etc., are the vanguard, and these alone may in favorable cases, arrest the microbian infection; but the really effectual fight is that waged by the leukocytes, but the leukocytes do not interfere in this way until the humoral antibodies have failed." . . . "The phagocytes from immunized animals display this new property even in vitro—a specific phagocytosis."

Epicondylalgia.—Maidágan cured a typical case of epicondylalgia in a boy of 12 by immobilization of the arm in semiflexion, leaving an opening in the dressings through which the region of the elbow was painted with iodin on alternate days. At the end of two weeks the elbow was lightly massaged and exercised and by the end of the month the pains and functional impotence were entirely overcome, and the cure has been permanent.

Mastoiditis in Infants Without Otorrhea.—Steinsleger has had to operate for mastoiditis in nine cases in young infants and there was no otorrhea in 77 per cent. in this group. One infant was only 45 days old, and the otitic origin of the mastoiditis was rendered evident by perforation of the mastoid on the seventh day of the abscess. In two cases an incision had to be supplemented later with the radical operation before a cure was realized. Mastoiditis in young infants seems to be relatively benign, and the child seems to bear it remarkably well. But this does not justify half-way measures; the results of such are deplorable. He never encountered any remote complications in young infants such as he has witnessed in older children. In the infants there was always caries of the mastoid process, and the operation was thus facilitated. Physicians should be on the alert to detect otitis in infants as it is much more frequent than generally imagined.

Infant Pathology.—Navarro warns that when the breast-fed infant is not obtaining its due quantum of breast milk, its resisting power is low and it is liable to develop fever with slight infections. The physician not realizing that the child is suffering from inadequate quantities of food is liable to shut off the food still more, and purge. Naturally the fever subsides with inanition, and the assumption is confirmed that the breast milk is the causal factor. Navarro emphasizes that disturbances for which the breast milk is actually reponsible are so rare as to be practically negligible in general practice, so this mistake should not be made. When the breast milk is being given in too large quantities, the disturbance is mild, moderate diarrhea, some vomiting but not severe or frequent, and some discomfort. Inadequate feeding is usually accompanied by vomiting and often with some infections in skin or throat or nose. If possible, a wetnurse giving more milk should be provided. If this is not practicable, cow's milk should be given in addition, modified as indicated. In infants between 1 and 4 months old, the cow's milk had better be given immediately after the child has nursed, to take advantage of the glands' secretions. Infants over 4 months old can have one feeding of cow's milk instead of the breast.

Optic Neuritis with Hypothyroidism.—The neuritis was bilateral in the woman of 24 with signs of mild, chronic thyroid insufficiency during the last seven years except in her three pregnancies. Three months after her last two pregnancies vision became impaired. By exclusion the optic neuritis was ascribed to the thyroid insufficiency and thyroid treatment was instituted. Vision improved essentially under it, but every time it was suspended the visual acuity dropped from ⅓ to ⅙. The optic nerve in the other eye had been atrophied for nearly four years. There was a family tendency to obesity, and the visual disturbance was probably a manifestation of some upset in the endocrine glands. The thyroid treatment aided in restoring the balance to a certain extent, and visual acuity of ⅓ was regained, but it dropped to ⅙ every time the thyroid treatment was suspended for about five days.

The Physician as a State Official. C. J. Brenkman.—p. 664.

Lymphadenoid Leukemia.—Peutz describes a case of acute leukemic lymphadenosis in a boy of 4. He was the ninth among thirteen children, and all the rest were apparently healthy, and he had always been well except that he seemed a little paler than the others. He began to show skin symptoms suggesting Werlhof's disease, followed in two days by hemorrhage from the kidney and enlargement of the spleen and peripheral glands, with death the eighth day. The blood was sterile and there was no fever, but the whites ran up to 720,000. He had had a fall two weeks before the first symptoms, and the shock from this, superposed on the status lymphaticus, may have brought on the disease.

*Osteoplastic Resection of the Knee. P. Panum.—p. 129.
*Vertigo. P. Lorenzen.—p. 136.
Carrel-Dakin Treatment Applied to Peace Time Surgical Lesions. P. V. Tuxen.—p. 141.

Osteoplastic Resection of the Knee.—Panum reports the details of three cases in which he applied Iselin's method of correcting ankylosis. A wedge is cut, but instead of removing the wedge it is twisted completely around until its base lies in the popliteal space, and heals in place here. The wedge does not have to be more than half the size of the wedge with resection, but the chief advantage of this technic is that the leg is not shortened by the operation. He makes a point of cutting the tendons preliminary to the resection, saying that in many cases of angular ankylosis the ankylosis might have been avoided if the tendons had been severed at the first resection. When the knee is flexed beyond 45 or 60 degrees it might be possible to apply this technic several times in succession, correcting only a part of the angle at a time. He reiterates that this osteoplastic resection is simple, certain and free from danger. He modified the Iselin technic in three of his six cases, cutting out a supplementary wedge.

Vertigo.—Lorenzen has noticed that dizziness for which the digestive organs are responsible is generally continuous but often with exacerbations in connection with meals, usually soon afterward, and is often accompanied with more or less nausea or other symptom of digestive disturbance. The dizziness experienced in an elevator or in looking down from a height he is convinced is of mental origin. It can generally be banished by seizing hold of something solid. He has encountered a number of cases in which a fibrositic affection in the muscles of the neck caused dizziness on turning to look back or other sudden movement of the head. He explains the mechanism of this dizziness and relates that a few sittings of massage of the fibrositic muscle put an end to the dizziness. In one severe case of the kind, the woman of 55 experienced this dizziness so much and so often that she did not dare to go on the street. Under eleven sittings of massage it disappeared and a few more sittings banished the last trace of the fibrositis. When the latter is of long standing, this cannot be counted on, but temporary relief is always obtained. Correcting digestive disturbance aids materially in the cure, as also measures to soothe the overexcitable nervous system.

*Conditions for Danish Science and for International Scientific Research After the War. T. Rovsing.—p. 337.

International Scientific Research.—In this address delivered to Danish students, Rovsing portrayed the opportunities which the present times offer to Denmark to take a leading place in international scientific conclaves. He commented further on the advantages that would accure to all if some one language were to be selected as the official speech for scientific assemblies. "At the present *moment*," he continued, "French stands a better chance for acceptance than any other language. The allied and the neutral countries would probably accept it without protest in consideration of the admiration and sympathy which France has won by its stand during the war."

*Paralysis of Respiration with Brain Abscess. G. V. T. Borries.—p. 325.

Paralysis of Respiration with Brain Abscess.—Borries reports a *personal* case of this kind and analyzes forty-seven he has found on record. It does not seem to be generally known that it may prove possible to resuscitate the patient even with *complete* arrest of the respiration, by immediate incision down to the brain abscess. Artificial respiration is only a makeshift and does not save the patient. There is one case on record in which touching the medulla oblongata with the finger started the breathing again, and this might be tried as the last resource. It acted possibly by releasing the impacted cerebellar tonsil. The Trendelenburg position may aid. Tracheotomy was done in seven cases, but it was probably done from misapprehension of the cause of the apnea. Artificial respiration and immediate incision down to the abscess should be tried in even the most apparently desperate cases. Coma with a brain abscess is no contraindication to the operation. Only in twenty-one of the forty-seven cases was the abscess opened up. The immediate effect of incising and clearing out the abscess was startling. In Borries' case the livid face abruptly changed to the normal tint and spontaneous respiration started up the moment the skull was opened, even before the dura had been incised. Borries' *patient* was a woman of 34 with symptoms of an otogenous cerebral abscess, and the sudden paralysis of the respiration was combated with artificial respiration and an incision in the temporal lobe. The woman began to breathe spontaneously and had no further disturbance in respiration till her death from the effects of the large abscess extending into the occipital lobe, found at necropsy. Borries is inclined to regard circulatory disturbance from some trivial cause as the last straw that upsets the precarious balance of the brain suffering from the compression by the abscess, tumor or accumulation of blood. This sets up a vicious circle. In his compilation of forty-seven cases, the lesion was in the cerebellum alone in thirty-two and in the brain alone in thirteen. The paralysis of respiration followed on lumbar puncture in quite a number of cases. Tabes and various poisons were responsible for it in other cases, and there are undoubtedly many instances of death from stoppage of breathing from an intracranial lesion, without special recognition of this factor.

*Circumscribed Edema. N. R. Christoffersen.—p. 381.
German Science Since the Armistice. J. W. S. Johnsson.—p. 408.

Circumscribed Edema.—Christofferson discusses the pathogenesis of Quincke's circumscribed edema, and describes various experiences which, in connection with the "war edema," seem to indicate that the internal secretions have more to do with it than has been suspected hitherto. In a case described in detail the little girl had been having hemorrhagic purpura, and the blood pressure was abnormally high. Transient edema developed in different regions in turn, and a marked tendency to retention of water and salt was evident although there was nothing in heart or kidneys to explain this tendency to edema. In this and other cases in his experience, he never found anything to suggest a peculiarly unstable nervous system.

*Tuberculous Glandular Disease in Relation to Pulmonary Tuberculosis. A. Wallgren.—p. 1.
The Course of Experimental Tuberculosis in Rabbits of Different Ages. A. Wallgren.—p. 127.

Prognosis with Tuberculous Glandular Disease.—Wallgren's *attention* was attracted to the rarity of lymphomas in persons with pulmonary tuberculosis, and to the apparently benign form of the pulmonary processes when they were associated with lymphomas. Examining the records at the Upsala clinic of 526 cases of tuberculous glands given operative treatment from ten to thirty years ago, he was able to trace the history since in 251 cases. Of the 79 with sound lungs at the time of the operation, 63 still are free from pulmonary disease; 9 have pulmonary tuberculosis; 5 had miliary tuberculosis and 2 tuberculous meningitis. Of the 29 with pulmonary tuberculosis at the time, 9 now have clinically sound lungs as also 3 of the 8 suspects. Of the total gland cases, 16.5 per cent. had pulmonary tuberculosis at the time. Of the total 224 traced cases, 3 per cent. had terminated with meningitis and 4 per cent. in miliary tuberculosis. On the whole, the pulmonary tuberculosis in these lymphoma cases seemed to be of a benign form. In 12 cases with a fatal outcome, the interval before death averaged five years; the range was from two to eleven years. Six of the patients were under 16 and only 3 over 30 years old. A number of writers have mentioned that in certain families some members develop pulmonary tuberculosis while others develop only tuberculous adenopathies and the lungs seem to escape. Among 516 tuberculous persons given treatment at the chest clinic at Upsala, only 1.7 per cent. had a history of enlarged and probably tuberculous glands before the onset of the pulmonary process. The general impression from the data presented, including a tabulation of statistics from various foreign clinics, is to the effect that the glandular disease augments the resisting powers, and determines a milder course if pulmonary lesions develop.

REHABILITATION OF THE DISABLED *

FRANK BILLINGS, M.D. (CHICAGO)
Colonel, M. C., U. S. Army
WASHINGTON, D. C.

I. REHABILITATION OF THE WAR DISABLED

The world war has aroused a universal interest in the physical and mental rehabilitation of disabled soldiers. The instruments of destruction of modern warfare sacrificed millions of lives and disabled a multitude of men. To conserve man power it became necessary for the European countries engaged in the war to study and apply all possible measures to protect the lives and health of the soldier. The use by the central powers of offensive and destructive measures in the way of high explosives, poisonous gases, liquid fire and other devices produced injuries requiring special measures of prevention and efficient surgical and medical management which could be developed only after careful research and study.

The final year of the war was illuminated by remarkable results of the practical application of known and new measures of prevention of disease, and military surgery reached a stage of technical skill and efficiency heretofore unknown.

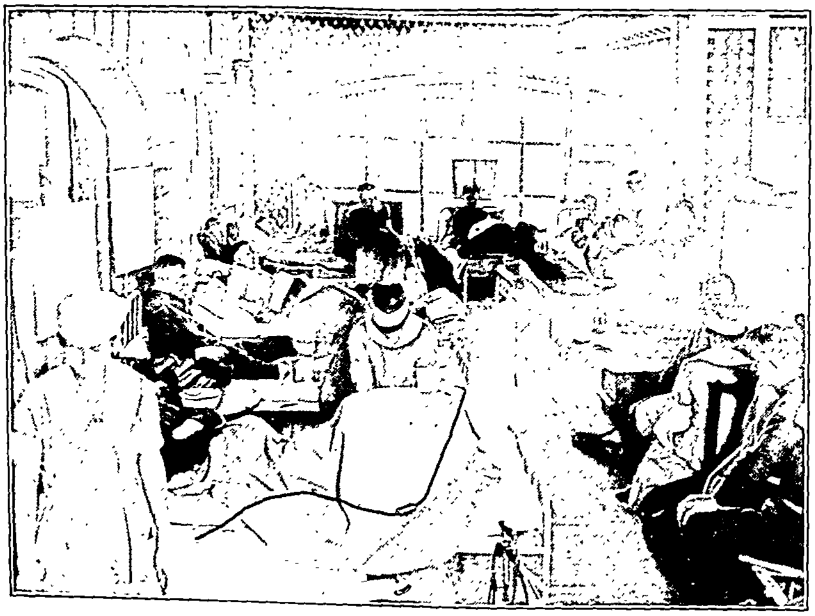

Fig. 1.—Application of thermotherapy.

EUROPEAN METHODS OF REHABILITATION

In addition to ordinary medical and surgical care, all the European countries engaged in the war adopted measures to hasten physical and functional restoration by the application of special therapeutic measures grouped under the heading of physical and mental reconstruction or rehabilitation.

The program of rehabilitation included physiotherapy, embracing hydrotherapy, electrotherapy and thermotherapy; exercise, passive (massage, mechanotherapy) and active (graduated calisthenics and special training, military drill and games in the gymnasium and out of doors); and occupational therapy in the application of manual and mental training and education in wards, workshops and schools and in gardens and fields. For the soldiers still fit for combat or for special military service, convalescent training centers were maintained, where, by means of military drill, instruction in individual and general hygiene, and play, the final hardening and restoration were completed.

All of the Allied countries of Europe together with Canada endeavored to train and educate the soldiers who were so disabled by disease or injury that they were no longer fit for any kind of military service, to qualify them to serve in the civilian industrial army. The rehabilitation program of these countries was carried on through a plan of cooperation of the military and civilian authorities. Limited time and space do not permit one to give here details of the program and the results of rehabilitation of the disabled as practiced by the Allied countries associated with us in the war.

AMERICAN PROGRAM

The United States became engaged in the war so late that our government was able to take advantage of the knowledge acquired by the entente governments by a bitter experience in defensive and offensive warfare, in measures of protection and prevention of injury and death. The Medical Department of our Army shared in the opportunity to apply the newer military medicine and surgery in the prevention and treatment of disease and injury. The program of our government for the care of the soldier and his dependents embraced:

1. The creation of the Bureau of War Risk Insurance, in the Treasury Department, with provisions for voluntary life insurance with the payment of a monthly premium of moderate amount from the soldier's pay;

---

* Read before the Institute of Medicine of Chicago, April 19, 1919.

* This article is abbreviated by the omission of some of the illustrations. These appear in the author's reprints.

provision for monthly allotment to the soldier's dependent family and provision for the payment of a monthly pension after discharge for a permanent disability acquired in the line of duty.

2. The Medical Department of the Army was authorized by the War Department to include measures of physical reconstruction in the treatment of the sick and wounded soldiers, including the employment of curative work carried to the degree of prevocational or vocational training and education, to fit them for further general or special military service; or if unfit for further military service to discharge them from the Army after the maximum physical and functional result was obtained.

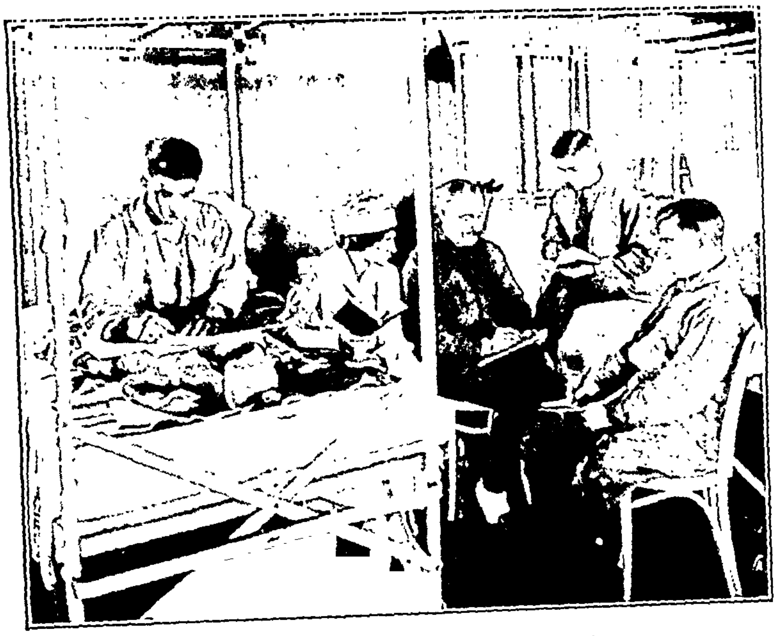

Fig. 2.—Ward class in academic study.

3. The Congress enacted a law approved by the President, June 27, 1918, which made the Federal Board for Vocational Education responsible for the vocational training and education of compensable disabled soldiers after their discharge from the Army.

4. The Congress has provided appropriations and has made the Public Health Service responsible for the hospital care of compensable disabled soldiers who may require treatment after their discharge from the Army.

The policy adopted by the Medical Department of the Army, in the attempt to fulfil its obligations to the government and the soldier, embraced a program of measures of prevention and treatment of disease and injuries, including mental and physical reconstruction or rehabilitation, based on accumulated experience and knowledge.

Advantage was taken of all available knowledge gained by the medical departments of the armies and governmental and other agencies of our Allies. American officers and American hospital units served with the English and French armies before we had developed an army overseas. Hundreds of these medical officers, medical enlisted personnel and American nurses acquired a first-hand knowledge of modern military medicine and surgery, enabling them to give efficient service in our own Army overseas and at home.

ORGANIZATION OF ARMY MEDICAL DEPARTMENT

One of the remarkable developments of the war was the organization of the Medical Department of the Army. Our country was unprepared for war on April 6, 1917. Our Regular Army establishment was efficient but small. The regular Medical Corps numbered less than 500 commissioned officers. As a rule they are a fine and upstanding body of men, many of them well qualified for administrative duty and as surgeons and physicians, a few with world wide reputation in research work and as sanitarians. At the call of the Surgeon-General the medical profession responded by volunteering for service. The large majority of these men were untrained in military tactics and knew but little of military medicine. But among them were many of the best qualified physicians, surgeons and specialists of our country. The majority quickly overcame the handicap of lack of pure military knowledge and gave service at home and overseas which evoked the praise of the chief commander of the American Expeditionary Forces and of the Surgeon-General. Nor must one lose sight of the spontaneous response of the medical profession to the call of the Provost Marshal-General for service on draft boards, and of the efficient manner in which this service was rendered.

DISEASE AND INJURY PREVENTION

The subject of rehabilitation of the disabled soldier involves the application of measures of disease and injury prevention. The principles involved in the problem of disease and injury prevention as applied to our army were made more difficult by many factors. Men were inducted into military service before the training camps were completed; it was practically impossible to place nonimmune suspects in detention quarters for a sufficient period of observation, and infectious disease carriers thus spread measles, scarlet fever and cerebrospinal meningitis among the susceptible troops. The winter of 1917-1918 was characterized by severe cold and much snow, and the newly organized Medical Corps officers were insufficient in number and many were inexperienced at the beginning in how best to deal effectively with the big and difficult problems. In the late summer and fall of 1918 the world wide severe epidemic of influenza reaped an abundant harvest of lives of soldiers and civilians. A malignant type of pneumonia characteristic of all epidemics of influenza was the chief cause of death. To all of these embarrassments in the application of measures of disease and injury prevention must be added the risk of the transportation of a large army in dense concentration by train in the United States and in France, England and Italy, and in equally crowded ships across the ocean. When overseas the soldiers met a trying

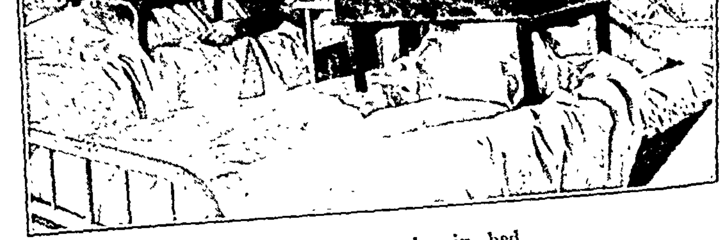

Fig. 3.—Telegraphy in bed.

climate, more or less uncontrollable insanitary environment of villages where they were billeted, or still worse conditions in the trenches or when advancing and living for days and weeks in a territory occupied by the armies of friend and foe for four years, the soil foul and infected; and finally they had to face a murderous, vicious foe who utilized every destructive element known to science and the devil to kill, wound or maim the opposing army.

But with all these embarrassments, difficulties and universal disability producing causes, the program of disease and injury prevention, and the medical and surgical management of our sick and injured soldiers was carried out by the Medical Department of the Army in a manner so successful that it justified the praise given by the chief commander of the American Expeditionary Forces and of the War Department.

In the making of our Army we selected the best of our young men from a physical point of view. Every man was immunized as a protection against smallpox, typhoid and paratyphoid fevers by standardized vaccines. Adequate clothing and blankets gave protection to the body. The American military shoe, the product of a research made by a regular Medical Corps officer, made him the best shod man of any army. Military drill and special training, discipline, life in the open, an abundant balanced ration and regular hours soon made an army of upstanding and physically fit men ready for any job. These new soldiers seemed to embody and demonstrate the spirit of patriotism of the nation. Physically and spiritually they had taken over new resistance to disease or injury. These same qualities made them bear disaster, when it fell, with courage and stoicism rarely seen in other men.

Overseas, special centers provided facilities for the correction of defects which were remediable by special training under qualified specialists and put the finishing touch on all. Prevention of combat injury was difficult at all stages of the war, owing to the nature of the weapons and destructive elements utilized by the enemy. Metal helmets and gas masks afforded some protection, but never wholly adequate.

During the last year of the war many lives were saved and in many cases permanent disability was obviated by the employment of efficient medical and surgical care. This modern military medicine and surgery was the outgrowth of the combined experience of the medical departments of the armies of the Allies and the United States, including cooperative research and clinical conferences.

FIRST AID

On the field the well trained medical personnel applied first aid and immobilized fractures with standardized splints carried to the field. This obviated further trauma of the tissues by the bone fragments during transportation to the rear. At evacuation hospitals within the combat zone and often subject to artillery fire, operations including the gravest major surgery were performed within a few hours after the injury was received. Unfortunately, in some battles a difficult terrain or in cases in which the battle was marked by fierce fighting and rapid advance, the evacuation of the injured was necessarily delayed. The soil of "no man's land" was always a source of danger of serious infection to the wounded. Nevertheless, the application of the new principles of prevention of additional trauma during evacuation from the field by proper fixation with splints, early and thorough cleansing of the wounds, by the removal of all foreign bodies and of devitalized tissues with open drainage obviated to a great extent gangrene and other serious types of infection, which were such a frequent cause of the loss of life and limb in the first years of the war. This explains the relatively small number of permanent disabilities through the loss of legs or arms of our disabled men. The successful application of lung surgery at evacuation hospitals and the life saving result is one of the remarkable events of the last year of the war.

The remarkable results of the treatment of the patients suffering from so-called "shell shock" is due to the application of the knowledge gained by military clinical experience. If this successful treatment had not been applied, thousands of soldiers would have been discharged suffering from types of mental and nervous disability. In the home environment and under the influence of the desire for a pension, many would become permanent invalids—an enormous loss to the industrial world and a continued financial burden to the government.

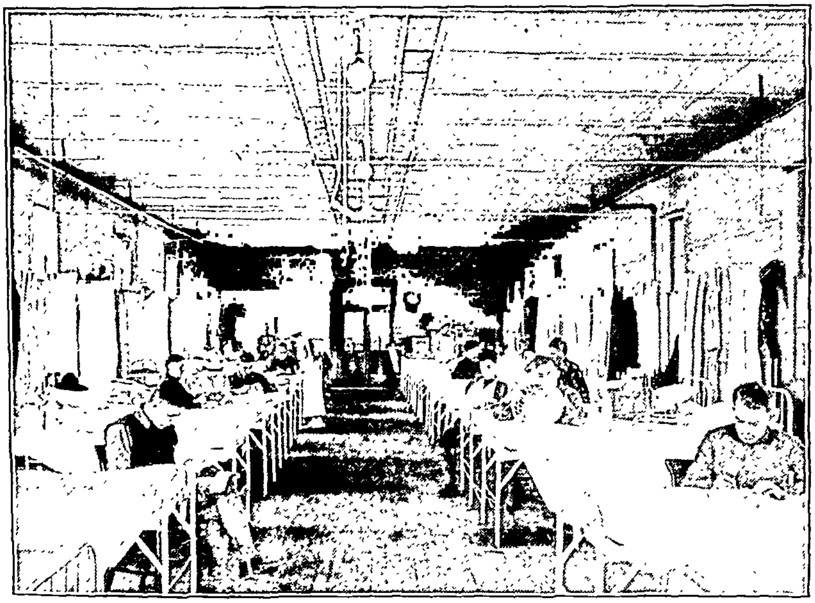

Fig. 7.—Curative work applied in the wards in the form of handcrafts.

STATISTICS AS TO DISEASE AND INJURY

In the discussion of the results of the application of measures of disease and injury prevention, I am permitted to quote available statistics. They are subject to correction after all data shall have been definitely verified. The deaths from typhoid and paratyphoid fevers in the domestic forces from Sept. 1, 1917, to March 28, 1919, were fifty. In the American Expeditionary Forces from Oct. 18, 1917, to March 28, 1919, there were 146, or a total in the U. S. Army of 196. This gives an annual death rate for typhoid and paratyphoid fevers of 0.06 per thousand. The efficient work of draft boards and of medical examining boards of training camps detected and rejected approximately 50,000 tuberculous men. Pulmonary tuberculosis developed in approximately 11,000 or possibly 12,000 soldiers, of whom 1,036 have died, giving an annual death rate in the whole army of 0.316 per thousand. The total deaths from other infectious diseases were: for meningitis, 2,055, giving a rate of 0.63 per thousand; measles, 119, or 0.036 per thousand; scarlet fever, 163, or 0.051 per thousand; dysentery, 41, or 0.001 per thousand; and empyema, 490, or 0.148 per thousand.

Fig. 9.—Curative work in shoeshop.

The pandemic of influenza complicated with a malignant type of pneumonia was the chief cause of death from disease in the Army at home and overseas. The medical profession, both civil and military, was unable successfully to institute measures of prevention or cure. The total number of deaths in the whole Army from Sept. 1, 1917, to March 28, 1919, was approximately 39,493, which gives an annual death rate of 11.997 per thousand. During the same period of time the total deaths from disease, including pneumonia, was 48,670, with a rate of 14.797 per thousand. The efficiency of the application of measures of disease prevention and of treatment is shown by the total deaths from disease alone, exclusive of pneumonia, which were approximately 9,177, giving an annual rate of 2.80 per thousand.

The efficiency of modern military surgery is evidenced by the official statement that 85.5 per cent. of combat injured soldiers of our Army returned to combat service, and 5 per cent. were made fit for special or limited military duty in the rear areas.

The remaining approximately 10 per cent. of the combat injured were so severely disabled that death occurred or the nature of the disability made them unfit for further military service. These included the blind, the deaf, patients with amputation of limbs, serious maxillofacial injury, serious peripheral nerve injury, empyema from trauma of lung or pleura, and other surgical conditions.

We may be justly proud of the accomplishments of the Medical Department of the United States Army in the world war. Serious mistakes occurred, due often to uncontrollable conditions and situations. The medical program of hospital construction, supplies, equipment, transportation and countless other needs had to be modified or to wait on other parts of the war program of the government. We know that many mistakes occurred, some serious ones, too, in regard to details, but the whole vast program of the government went through. The end sought was obtained much earlier and more satisfactorily than was anticipated. If the big governmental program had been carried through less expeditiously, perhaps fewer mistakes would have been made in all departments. But had we worked with less haste one wonders whether the Allied armies would now be astride the Rhine.

The policy of the Medical Department for the physical reconstruction of disabled soldiers and later extended to disabled sailors and marines, was formulated in August, 1917, applied in some of the general military hospitals early in 1918 and approved by the War Department July 29, 1918. Physical reconstruction was defined as continued management and treatment carried to the fullest degree of maximum physical and functional restoration, consistent with the nature of the disability, by the employment of all known measures of modern medical management, including physical therapy, manual and mental work and recreational play.

To carry out this policy a program was formulated to establish a department of education and a department of physiotherapy in each of the general military hospitals designated by the Surgeon-General to function in the physical reconstruction of disabled soldiers. A division of physical reconstruction in the Surgeon-General's Office was organized, with a director to be responsible for the administration of the work. Subsections on education and on physiotherapy, each with a director, were established in the division.

PERSONNEL OF EDUCATIONAL DEPARTMENT

To establish the educational department with efficient standards the Surgeon-General was fortunately able to secure the services of Dean James E. Russell of Teachers College, Columbia University, to serve as the administrative director. Dean Russell was unable to accept the place permanently, but volunteered to give his services in an advisory capacity for several days of each week in the organization of the educational department. This he did without compensation for the period of five months, when he was obliged to return to his duties at Columbia College. Dean C. D. Coffman of the University of Minnesota occupied a similar position in the office as a volunteer without compensation on the retirement of Dean Russell.

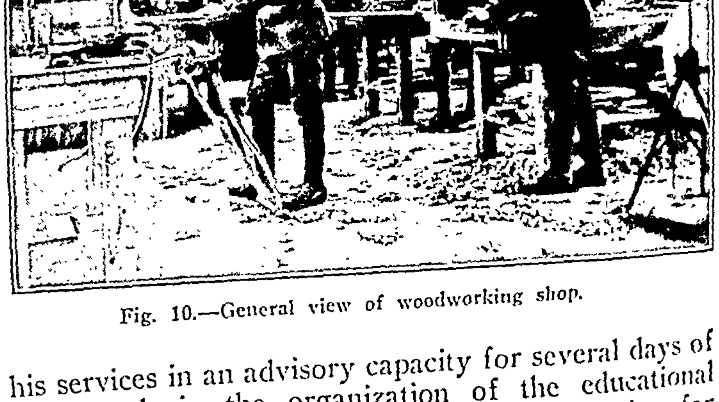

Fig. 10.—General view of woodworking shop.

Through the efficient service of these two patriotic men, aided by other qualified general and special educators, who came into service commissioned in the Sanitary Corps of the Medical Department, the Surgeon-General was enabled to establish educational departments and the needed personnel in each of the military hospitals where the work was required. Each hospital was supplied with a chief educational administrative officer, commissioned officers qualified as general and special educators and psychologists and noncommissioned and enlisted men able to serve as teachers and instructors of patients in the application of curative work in the program of physical reconstruction.

The director of physiotherapy in the office was able to secure a sufficient number of qualified medical officers to serve as directors of the work and a personnel of other commissioned officers, noncommissioned and enlisted men and trained qualified women aides in physiotherapy efficiently to apply physical treatment to disabled men.

Recreation in the form of exercise in gymnasiums and out of door games was secured through the American Red Cross cooperating with the Y. M. C. A., the Knights of Columbus, the Jewish Welfare Board and in the base hospitals and convalescent centers through the War Department Training Camp Activities.

WARD WORK

In the application of the curative workshop schedule, work in the wards for bed and chair patients was applied by women as reconstruction aides in occupational therapy. These women were qualified for the work by experience as teachers in high schools, colleges and universities in civil life and by special training in arts and crafts. Some of them had served in civil life as social welfare workers.

The ward work has proved of the greatest value in the cure of patients. Primarily, application of the work served as a diversion by arousing the interest of the patient and by distracting him from a contemplation of his disabled condition, whether due to sickness or to injury. At the beginning the schedule of ward work consisted of simple handcrafts in the form of knitting, beadwork, basketry, mat-weaving, block stamping, wood-carving and the like. As the work progressed, it was found that the interest of the patient was more readily aroused by work that was prevocational or even vocational in character, because it prepared him for the occupation that he would follow after discharge from the army or for further education and training by the Federal Board of Vocational Education. Consequently stenography, typewriting, mechanical drawing, winding electrical armatures, academic and commercial study and the more purposeful handcrafts were utilized.

As rapidly as possible buildings were altered or new ones constructed for workshops and schools, equipment installed, books were obtained through the American Library Association, and the convalescent patients were sent to the shops and schools for the application of the doses of work prescribed by the ward surgeons.

SHOP WORK

The schedule of work in the shops consists of motor mechanics, boot and shoe repairing, harness making, carpentry, electrical installation, printing, mechanical drafting and the like. In the gardens, landscaping and truck gardening are taught; on farms, ordinary farming, including stock breeding, dairying, poultry raising, hog raising and farm economics. Greenhouses are utilized at many centers to train men in horticulture and to grow vegetables. In the schools academic studies in common school branches including left hand writing are taught. Incidentally, aliens, and especially the illiterates, are educated and then naturalized as American citizens. Commercial courses are given in shorthand, typewriting, bookkeeping, banking, buying and selling, and many other branches.

SPEECH DEFECTS

At the U. S. General Hospital No. 11, Cape May, an efficient school for the disabled soldiers with deafness and defective speech successfully teaches lip reading and the correction of speech defect. The patients coincidently receive prevocational or vocational training.

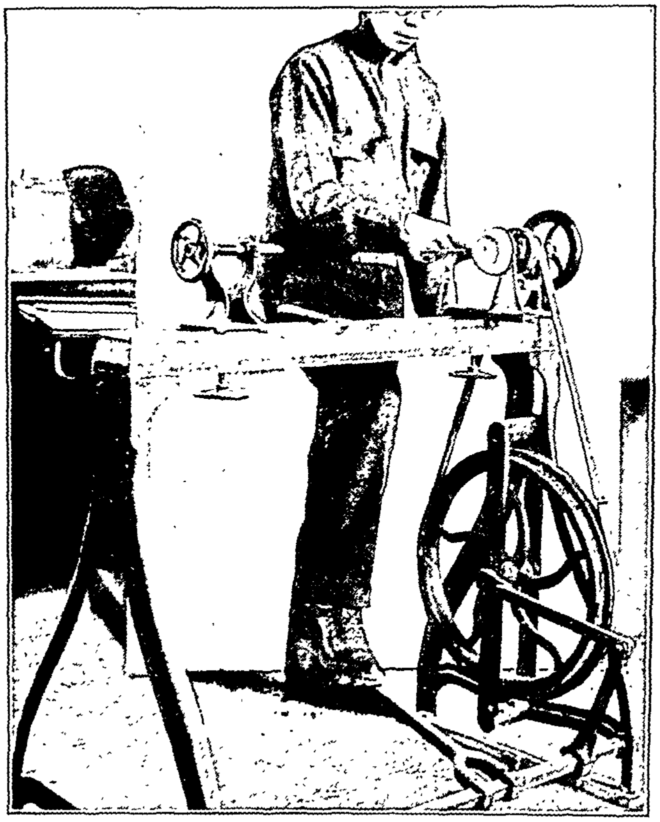

Fig. 11.—Curative work: Application of foot treadle to exercise disabled knee.

CARE OF THE BLIND

At the U. S. General Hospital No. 7, Roland Park, Baltimore, there has been established a school for the blind or nearly blind soldiers, sailors and marines. The blinded soldier is taught how to dress, feed himself and get about as an independent person, at the same time thorough instruction is given in Braille and coincident training in occupations suitable for the blind. In this connection, there are approximately one hundred totally blind, and approximately one hundred partially blind soldiers, sailors and marines.

THE TUBERCULOUS

The schedule of curative work applied to the disabled soldier suffering with pulmonary tuberculosis was modified to meet the varying clinical conditions under constant watchful medical supervision. Curative work for the tuberculous soldier has proved of the greatest value in the prevention of hospitalization and for the convalescent in the production of the final hardening process so valuable in the prevention of relapse, when the stage of inactivity of the disease has been secured.

SPECIAL CENTERS

A few of the general hospitals have been designated as special centers for the treatment of the nerve injuries, the maxillofacial mutilations, and of the amputation cases. At two or three centers, provisional artificial limbs and protheses are manufactured. There the men with amputations are fitted and trained in the use of the artificial appliances. In this connection it should be stated that the Bureau of War Risk Insurance is responsible for furnishing the discharged soldier with the needed permanent artificial limb.

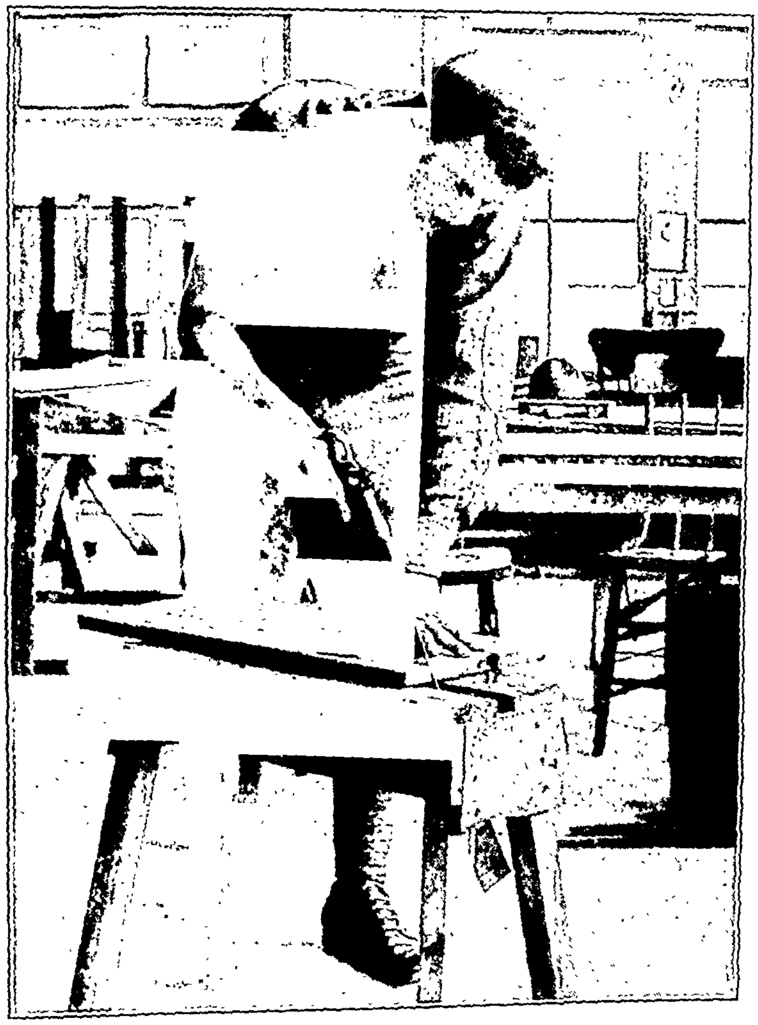

Fig. 12.—Curative work applied in the act of sawing, to improve the mobility of the elbow.

COOPERATION

In the application of curative work in the treatment of disabled soldiers it has been the endeavor to secure cooperation between the ward surgeons and the educational department. It has been recognized that the justification of the adoption of work as a therapeutic agent involves control by the surgeon and physician; that while the educational officer may evolve kinds of work, which to accomplish the end sought requires known muscular action, it is the surgeon or physician who must indicate the particular function to be restored and to prescribe the dose of work, the time it is to be given and the frequency of its repetition. The same cooperation is necessary between the clinical staff and the director and his personnel in the application of physiotherapy.

"CHEER UP" PROPAGANDA

For the information of the disabled soldiers circulars and bulletins have been published by the Medical Department of the Army outlining the program of physical reconstruction in the military hospitals. "Cheer up" propaganda has been placed in the hands of the patients and for their benefit, and, to educate the general public on the need of physical and functional rehabilitation, the Surgeon-General has published and distributed, with the cooperation of the American Red Cross, a magazine *Carry On*.

Cooperating with the Federal Board for Vocational Education, the Surgeon-General has compiled and published courses of study in pamphlet form, covering all phases of study and occupations as guides to teachers and patients, in the application of the curative workshop schedule in the wards, shops, schools, gardens and fields.

To the date of the signing of the armistice the educational activities applied in the treatment of the disabled soldier justified the vocational training of the convalescent soldier to fit him for further special military service. Until that date the general hospitals which functioned in the physical reconstruction of disabled men returned many men to general or special military service, and of these, the majority had been sent to the hospitals, with the belief they could not be made fit for further military duty. The application of curative work, physiotherapy, military drill, special training and play were the decisive factors in securing such complete physical and functional restoration that they were able to return to military duty.

THE RETURNED DISABLED SOLDIER

Following the signing of the armistice and the cessation of hostilities it was no longer necessary to keep the disabled man in overseas hospital until restored, because he would no longer be needed for the military service unless he had enlisted prior to April 6, 1917. Consequently, it became necessary to amplify the centers in this country for the physical reconstruction of the large number of disabled men from overseas who returned to America for treatment. To meet this need facilities were provided by the War Department at the request of the Medical Department, for physical reconstruction of disabled soldiers in departmental base hospitals and in base hospitals of the National Army cantonments. Additional general hospitals were also equipped for the work until a total of forty-nine hospitals were designated to function in the physical reconstruction of disabled men. In addition to the hospitals, nineteen convalescent centers were established in the training camps of the country to which convalescent detachments from overseas and convalescent patients from the hospitals of this country were distributed, each one sent to the center nearest his home, for a final process of hardening by the application of curative work both manual and mental, by general and special physical training through military drill and calisthenics, and by exercise at play in gymnasia and out of doors.

Since the armistice was signed the policy of the Medical Department of the Army is to discharge the disabled man as soon as he shall have reached the maximum physical and functional restoration, consistent with the nature of the disability. This leaves to the Federal Board for Vocational Education the responsibility for the occupational training and education which is the privilege of the compensable disabled soldier if he desire to take it. The application of physical reconstruction or a better term, physical and mental rehabilitation of disabled soldiers, has been justified by the result in the military hospitals of this country. With a small beginning it has grown within a year of practical application to a large establishment.

PERSONNEL

The personnel of educational officers with their subordinates, noncommissioned officers, enlisted men, as qualified administrators and instructors are as fine a body of men as one will find anywhere. They have given patriotic and efficient service to the country and have been and are recognized factors in the more complete physical and functional restoration of disabled men, who have thus been made fit to return to their old or a new occupation or have been physically and mentally prepared to take advantage of the opportunity for vocational training and education under the authority of the Federal Board.

Approximately eight hundred reconstruction aides in physiotherapy have given efficient service in the application of local baths, electrotherapy, massage and passive exercise to disabled men at home and overseas.

Approximately fourteen hundred reconstruction aides in occupational therapy have rendered service of the highest efficiency in the application of mental and manual work for the patients in wards in overseas and in domestic hospitals. These women who have served the government as reconstruction aides in physiotherapy and in occupational therapy are deserving of the highest praise for the work they have done for the disabled men.

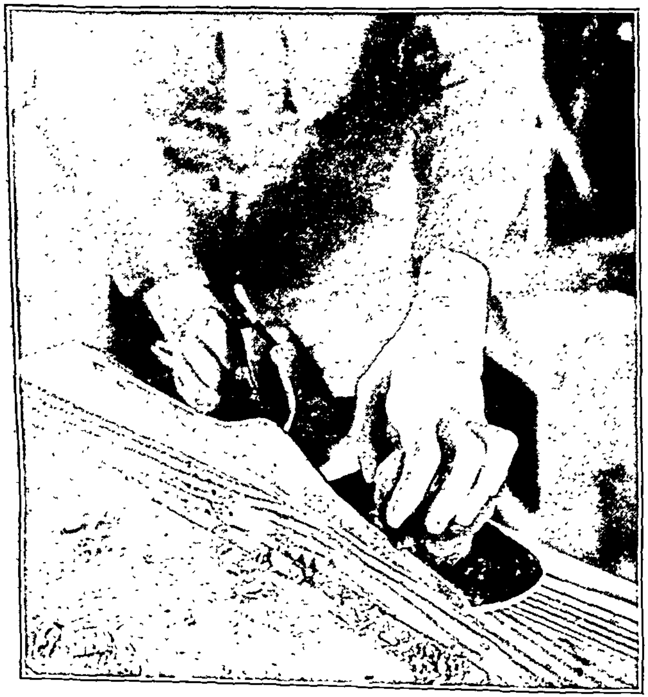

Fig. 13.—Curative work; using carpenter's plane with molded hand grip to exercise disabled hand.

It is common expression of all officers who have come in contact with the disabled sick and wounded soldiers that the application of curative work and physiotherapy has done much to improve the morale, maintain discipline, prevent hospitalization and to hasten and make more certain the cure of the patients.

PERMANENT POLICY

It is believed that the experience and application of curative work and standardized physiotherapy in the military hospitals during the emergency created by the war, will become a permanent policy of the military establishment of the United States. This policy will necessitate the designation of certain general and military post hospitals to function in the physical reconstruction of the sick, injured and disabled men. Facilities for this work in military hospitals will include the application of curative work that is vocational in character. Vocational training in the military hospital is justified by law and by the fact that the disabled soldier may continue in military service provided the nature of the disability permits restoration consistent with further service. The vocational training and education received while a patient will make him of greater value as a soldier and at the expiration of his term of enlistment, should he decide to return to civil life, he will serve with greater efficiency in the industrial army.

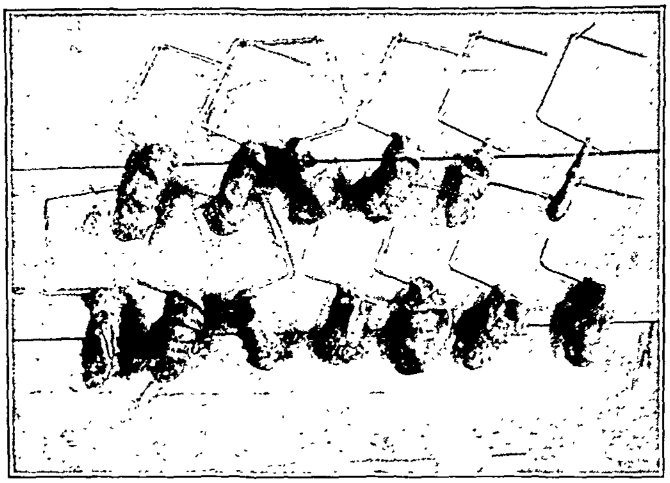

Fig. 14.—Examples of plastic wax handles for jig saws molded to fit individual disabled hands.

II. REHABILITATION OF THE DISABLED OF THE INDUSTRIAL ARMY

It has been stated that 750,000 people of eighteen of the United States of America are injured annually in the industrial occupations. Of these, 35,000 are permanently disabled. It has also been stated that 80,000 people are permanently disabled annually in the whole United States through accident received in industrial occupations. Of these it is stated that 2,000 are totally disabled.

This enormous crippling or entire loss annually of the industrial workers has not received the consideration due these unfortunates by federal, state or local governments, or by corporations engaged in industrial work.

Sporadic attempts have been made by local communities or by corporations to overcome the handicap due to the disability by the application of measures of physical and mental rehabilitation. But, as stated, the attempts have been purely local, small in character as compared with the enormous problem and have been characterized by partial success only because of the

SOME OBSERVATIONS ON THE SURGICAL TREATMENT OF GONORRHEAL EPIDIDYMITIS

WITH TECHNIC OF OPERATION

ARTHUR B. JAMES, M.B.
Captain, C. A. M. C., Canadian Hospital, Etchinghill, England
TORONTO, CANADA

Owing to the war, with the visible increase of gonorrhea, and to the many opportunities for observing and recording cases in army practice, it has been possible to collect a large number of case records of the various types with their complications. The purpose of this paper is to draw some conclusions from the results obtained by the surgical treatment of gonorrheal epididymitis.

Various writers have placed the incidence of gonorrheal epididymitis at from 10 to 25 per cent. It has been 15 per cent. during the past year at the Canadian Special Military Hospital, Etchinghill.

Cases of epididymitis show a distinctly longer stay in hospital than many other complicated types of gonorrhea. In addition they are a frequent source of relapse of the urethritis, the cause of sterility on the side affected in a very high percentage of cases, and the reason for a great deal of acute pain and discomfort to the patient. The operation of epididymotomy was commenced as a routine measure with a view of shortening the duration of treatment in hospital, of reducing the liability to sterility and of relieving symptoms.

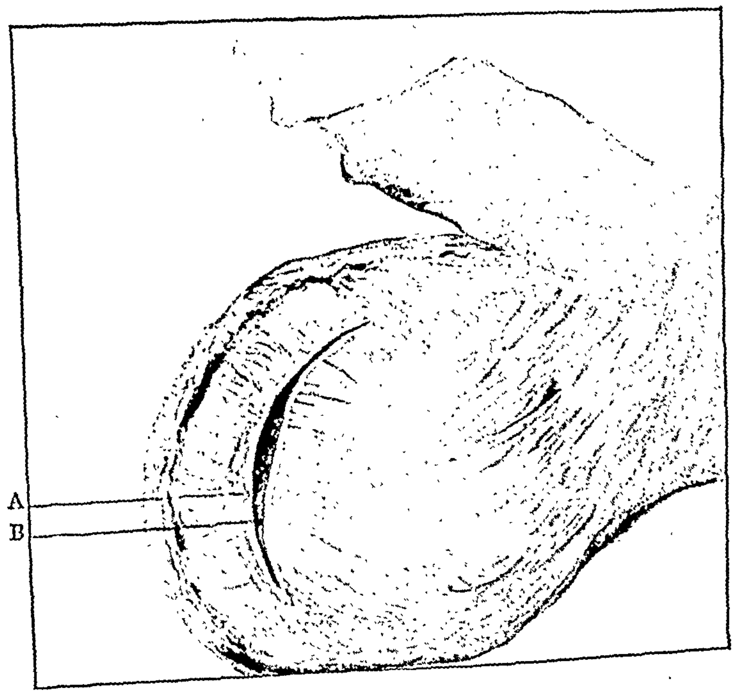

Fig. 1.—Initial incision: *A*, dartos; *B*, cremaster.

I have observed two distinct types of gonorrheal epididymitis; first, the subacute type, coming on slowly, in which the epididymis never becomes much larger than a man's thumb, with only a slight hydrocele and very little edema or redness of the scrotum. In these cases the pain is not acute, and constitutional symptoms are not marked. It is seldom that these cases develop into the second or acute type, in which the onset may be, (*a*) slow, resembling the beginning of the subacute type, but gradually progressing in a few days, with intense pain, marked redness and edema of the scrotum, pain in the cord, radiating into the iliac fossa, accompanied by hydrocele, fever and high leukocyte count; (*b*) rapid, commencing with pain, swelling, edema, fever and hydrocele, progressing to an acute stage within from twenty-four to forty-eight hours. These types are due undoubtedly to the degree of virulence and to the strain of the infecting gonococcus.

There may be three channels of infection: (1) direct extension through the urethra, ejaculatory ducts, vesicles and vas; most observers incline to believe in this method of infection; (2) the lymphatics, which to my mind constitute a more common channel of infection than is generally supposed; (3) the blood stream, which is least likely.

If we consider the pathology of an acute epididymitis, we find that the epididymis becomes enlarged, tense and painful, and on section it is found congested, showing tubules distended with some fluid exudate. Frequently this passes on to actual abscess formation. The exudation which causes most of the enlargement is due to the inflammatory process around and between the convolutions of the tubules and duct of the epididymis. If this process goes on to pus formation, small cavities fill with pus and form small localized intertubular abscesses. The cells of the ducts are infiltrated, a certain amount of epithelium is shed, and the lumen contains a mixture of pus, epithelium and spermatozoa. The inflamed surface of the tunica vaginalis gives off an exudate which is at first clear, and later may contain pus and fibrin, or even go on to definite pus formation. It is claimed that a great deal of the pain present is due to the tension caused by the hydrocele. My personal experience has been that this is not the case, but that the tension occurring within the fibrous tunica covering the epididymis, caused by the inflammation and edema of the body, and which sometimes extend up into the cord, is primarily responsible fo the pain. Hagner[1] in his original article quotes Monod and Terillon, who have shown that the enlargement of the epididymis is due to the edema or inflammatory exudate occurring in the cellular tissue surrounding the tubules rather than to any changes in the tubules themselves. After having dissected off the fibrous tunica from the cord and having made an opening in its upper and anterior border, they were able to fix a cannula into the cellular tissue and to inject through the cannula a weak solution of gentian violet. When the fibrous tunica had been sufficiently filled they saw that the infiltration characteristic of this special form was reproduced and resembled an increase in size of the epididymis. Hagner himself has duplicated the above experiment.

I have found the globus minor to be the part of the epididymis most frequently involved, the body more rarely, and the globus major least frequently. In one of my cases I found the entire body of the epididymis destroyed; a large abscess communicated directly into the testicle, of which a mere shell remained, owing to the great destruction of tissue. It was deemed advisable to remove the testicle.

When resolution commences the hydrocele is gradually absorbed, the tunica vaginalis is in many cases bound down by dense adhesions, either to the tunica albuginea or to the cremasteric fascia, or to both. Often absorption does not take place and a chronic hydrocele results. Within the epididymis itself the pus may be absorbed and the resulting pocket filled with fibrous tissue. Even the cells of the tube itself may become fibrosed, and from the resulting contraction the lumen may be occluded. It frequently happens that this process takes place en masse, and we have a resultant hard fibrous nodule which is usually felt, even for years afterward, in the globus minor. In some cases the gonococcus is harbored in the center of these nodules and may be the cause of a subsequent reinfection or recurrence of the urethritis. Baerman[2] has found gonococci in foci in the epididymis years after the infection occurred. It is undoubtedly true that a great proportion of these patients showing nodules are sterile on the side involved.

---

[1] Hagner, F. R.: Ann. Surg., 1908.

The advantages of operative interference in cases of gonorrheal epididymitis of all types are numerous. It is considered good surgery to evacuate pus in any locality. In my experience, if done for the relief of pain alone, the operation of epididymotomy is justifiable. Following Hagner, several observers have recorded their findings and results in a very convincing manner, and yet today this operation has not been generally adopted in the treatment of epididymitis.

The chief objections to operation appear to be:

(1) There is danger of injuring the tubule of the epididymis. There is very little danger of severing a tubule if care is taken and the proper technic is employed. Even though a tubule is severed, in my opinion, it soon unites or anastomoses. When we consider the remarkable reparative property of the vas, as illustrated in cases in which it has been severed with a view to causing sterility in certain mental subjects and in habitual criminals and has later reunited and functionated, it seems that the same may be probable in the epididymis.

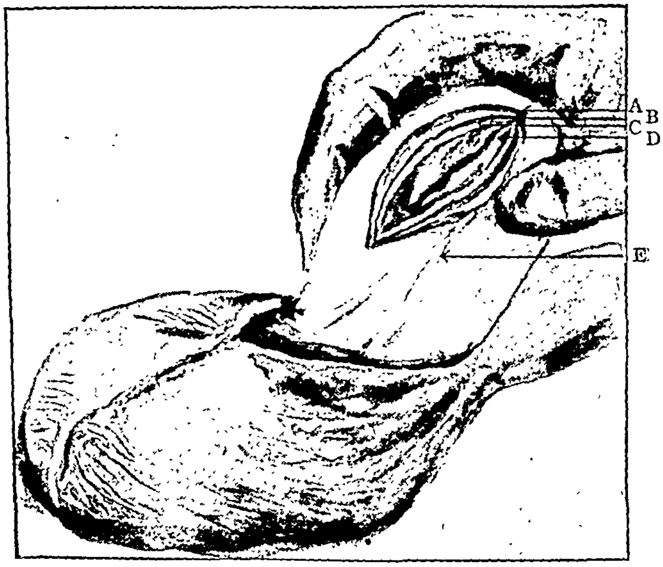

Fig. 2.—Incision exposing the epididymis: *A*, parietal lamina of tunica vaginalis; *B*, visceral lamina of tunica vaginalis; *C*, tunica albuginea; *D*, epididymis; *E*, veins.

(2) Puncture of the epididymis is an efficacious form of treatment. Many urologists adopt this procedure and report good results. My experience has been that puncture only temporarily relieves tension and pain, and usually does not favor early resolution, nor does it prevent fibrous tissue formation. It seems clear that though fluid may be aspirated by a small puncture made with a needle, there can be no drainage, and while the process is acute the edema or exudation soon causes again tension in the fibrous capsule.

(3) Epididymotomy is too radical a procedure to become popular. The operation is simple, however, and should take only a few moments to perform. If we can prevent or lessen the liability to sterility by its use it is clearly indicated.

Hagner[1] states that in every case in which he has operated fluid was present. He notes a marked falling off in the leukocyte count after operation. Reporting on nineteen of his own and two other cases, pus was present in seventeen of the twenty-one cases; in the globus minor in twelve cases, in the globus major and minor in three cases, in the globus major in one, and in the tunica vaginalis in one, the latter having no abscess involvement of the epididymis. In these twenty-one cases the gonococcus was demonstrated five times in the pus from the epididymis, and once in pus from the tunica vaginalis, when none could be found in the epididymis. He lays stress on the rapid disappearance of induration in both the cord and epididymis after operation, and states that nine patients have had a hard nodule of the globus minor, lasting for a long time, such as persist so frequently in those treated without operation. The average time before his patients were up was five days. He also observes that the discharge in patients treated medically increases after the swelling goes down, but decreases in patients after operation.

Baerman[2] states that in a considerable proportion of cases of epididymitis abscesses are formed, and that suppuration is regularly followed by the appearance of the hydrocele. He advises early interference to save the canal from occlusion.

Eckels[3] observes that the usual symptoms—pain, swelling, dragging, etc.—are proportionate to the amount of fluid secreted. Consequently, the liberation from its sac of this fluid immediately relieves all symptoms. He states that if the disease can be arrested in its first stage by the method under consideration, pus and abscess formation can usually be avoided. Thus he argues that in an attack mild in character and seemingly amenable to medicinal treatment the operative plan is the more expedient. In my experience I have found this to be true. It is certain that in no case in which I have operated has there been any tendency for the process to increase after operation.

Eckels' conclusions are:

> The relief of pain is instantaneous; internal administration of sedatives, opiates or loathsome external applications are unnecessary. The abatement of fever takes place in from twenty-four to forty-eight hours. Swelling, tenderness and other symptoms rapidly disappear. There is no tendency to recurrence. There is insured a minimum of time lost from usual activities, and there is probably a smaller percentage of sterility following the disease.

Knight[4] agrees with Eckels in all of his statements, and reports five cases in which he used local anesthesia.

Crosbie and Riley[5] report twenty-eight cases, two of which were bilateral. They first used general, but now use local, anesthesia. Their method of inducing local some due to fibrous induration caused by the inflammatory process. The operative advantages as to the end-result following resolution can be aptly demonstrated in several cases in which there has been a bilateral infection, one side of which has been operated on and the other treated otherwise. Without exception these cases show less thickening on the side where surgical interference has been employed. Several of these patients had been treated expectantly on one side before I had commenced epididymotomy as a routine measure. This observation throws some light on the point of resolution in favor of surgical interference.

---

[3] Eckels, L. S.: J. A. M. A. 61: 470 (Aug. 16) 1913.

[4] Knight, C. P.: Epididymotomy, J. A. M. A. 62: 351 (June 31) 1914. Culler, R. M.: Epididymotomy, J. A. M. A. 60: 415 (Feb. 8) 1913.

[5] Crosbie and Riley: Boston M. & S. J., May 6, 1913.

I have yet to encounter a case in which the operation has not almost immediately relieved the pain. There have been a few patients who complained of tenderness a day or so later.

In a comparative study of fifty patients treated by the operative method and fifty treated otherwise the following points are brought out: Of the fifty operative cases, pus was found in 80 per cent., either macroscopically or microscopically, and in those in which pus was found the gonococcus was present in 32 per cent.

Bazet[8] found gonococci in 33 per cent. of his cases. The wound, including the sinus, healed in an average period of fourteen days. Pain was present in varying degrees in all cases, and was relieved in from two to forty-eight hours.

There was a hydrocele present in 90 per cent. of cases, and in the 10 per cent. not having hydrocele the pain was relieved immediately following operation. In the fifty nonoperative cases pain was present in varying degrees in 98 per cent. The accompanying table shows the comparative length of time in which pain was relieved; also the comparative end-results when resolution was considered complete.

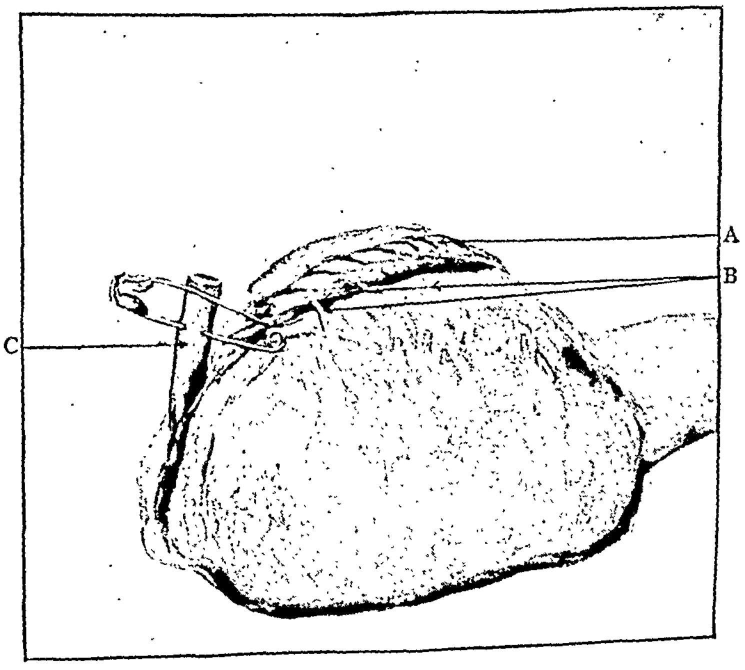

Fig. 5.—Final sutures: *A*, silk skin suture; *B*, silkworm-gut mattress retention sutures; *C*, drainage tube.

In the nonoperative series it is interesting to note that three cases have relapsed, or reinfection of the original process has taken place, at some period following primary resolution. In one case in the series there were three such relapses. In one case there was a nodule as large as a walnut, which was still quite tender, although the original infection had occurred in the year 1912.

TIME REQUIRED FOR RELIEF OF PAIN AND FOR COMPLETE RESOLUTION, WITH END RESULTS

	Pain Relieved Within	Average Days Resolving	Complete Resolution Per Cent.	Very Slight Thickening, Per Cent.	Moderate Thickening, Per Cent.	Marked Thickening, Per Cent.
50 operative cases	24 hours	30	40	58	2	0
50 nonoperative cases	3-6 days	40	8	60	30	2

This is in marked contrast to the results obtained by the operative method. There were no relapses in the series, and in only one case was there a suspicion of reinfection. In this case the drain was removed within twenty-four hours and for two or three days there were some tenderness and pain, but no increase in size. The process subsequently went on to rapid resolution.

It was also noted that the shorter the duration of the epididymitis prior to operation, the shorter the period of resolution. This seems to prove that early interference, that is, before the tunica vaginalis becomes thickened, fibrin deposits are formed, and chronic infiltration takes place, or before pus foci are formed, is the proper procedure in cases of acute epididymitis.

The observations as to the improvement of the urethritis are markedly in favor of the operative series. In over 50 per cent. of the nonoperative cases a relapse of the urethritis occurred, while of the operative cases only 4 per cent. relapsed.

It has not been possible, in the cases selected for comparison, to note the findings in the vesicles, but it would be interesting to follow up these cases from the standpoint of vesicular infection or reinfection following the epididymitis.

CONCLUSIONS

1. Early operation is advised to prevent destruction or occlusion of the tubules.
2. The pain is relieved almost immediately by surgical interference.
3. The process is considerably shortened.
4. No accurate conclusions as to sterility may be made except in bilateral cases, but present evidence favors epididymotomy as a means of preventing sterility.
5. There is less liability of a recurrence of the urethritis.
6. The operation should be more generally employed.

Canadian Hospital, Etchinghill, Kent, England.

Tuberculosis Among Industrial Workers a Home Problem.—A special report of the Medical Research Committee of Great Britain deals with the prevalence and etiology of tuberculosis among industrial workers. The city of Birmingham was selected for a special inquiry and the nonferrous metal trade was chosen. Forty works were visited and inspected thoroughly and as many of the notified persons as could be identified were questioned about themselves. A dangerous proximity was observed in certain departments, the girls working very close together. The objectionable habit of spitting into the receptacles which hold the lubricating mixture, found in all shops where "wet" metal work is carried on, is condemned as being a disgusting and possibly a dangerous practice. No evidence of any other dangerous trade habit was found. The home housing conditions were found very unsatisfactory in many parts of the central or crowded area, and the evidence goes to show that the home is really the principal place of infection either through contacts or imminent in the house itself.—*Med. Officer* **21:** 121, 1919.

DISSEMINATED NECROSIS OF THE PULMONARY CAPILLARIES IN INFLUENZAL PNEUMONIA *

E. R. LeCOUNT, M.D.
Consulting Pathologist, United States Public Health Service
CHICAGO

One of the difficulties in attempting to find an explanation of either the hemorrhage or the huge edema[1] of the lungs in influenzal pneumonia is that many different stages are encountered, most of them well along or late in the disease.

Very early in this attempt, attention was directed to the presence of a layer of fibrin close to the lining of the alveoli and ducti alveolares, often a very thin layer and in some instances the only fibrin present. With lobar pneumonia (by this term I mean a disease which is lobar pneumonia not only anatomically but also clinically), such a limitation of the fibrin deposit to the alveolar lining is not common.

Another outstanding condition is the necrosis of the alveolar lining epithelium, which appears early as a hyaline layer in which the outline of the separate cells is entirely lost, thus becoming a layer of necrotic cells sometimes with fibrin on its inner surface or in it and in some instances with very little fibrin anywhere else in the alveoli. Later in the disease these cells are reproduced and the large new cells may be found with mitotic nuclei in them.

DISSEMINATED CAPILLARY NECROSIS

While studying these as well as other conditions, I encountered a feature of the changes in influenzal pneumonia which may throw some light not only on the hemorrhages but also on the edema. This feature, a disseminated necrosis of the interalveolar capillaries, is readily found in places markedly changed, where the alveoli are already filled with blood or plasma, with the addition at times of the comparatively slight leukocytic exudate so characteristic of influenzal pneumonia. But with such changes it may well be inferred that necrosis of the interalveolar walls and of the capillary meshwork they contain is altogether secondary to alterations within the air sacs. But examination of many sections from many postmortem examinations has revealed some conditions in which such an inference of necrosis secondary to the pneumonia may well be doubted, and the accompanying photomicrographs are an attempt to set these lesions clearly forth with the hope that others, too, will search for them.

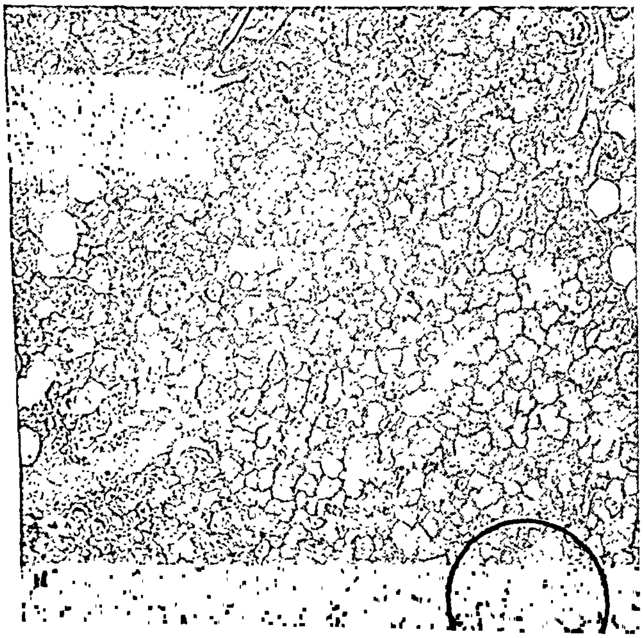

Fig. 1.—Most acini in this section of about 7 sq. mm. of lung tissue from a patient who died from influenzal pneumonia contain some red blood corpuscles, some none; all contain some leukocytic exudate. Edema is more widespread than either of these alterations. The necroses indicated by Fig. 2 are everywhere as abundant as in the small part of the section selected for Fig. 2; × about 14.

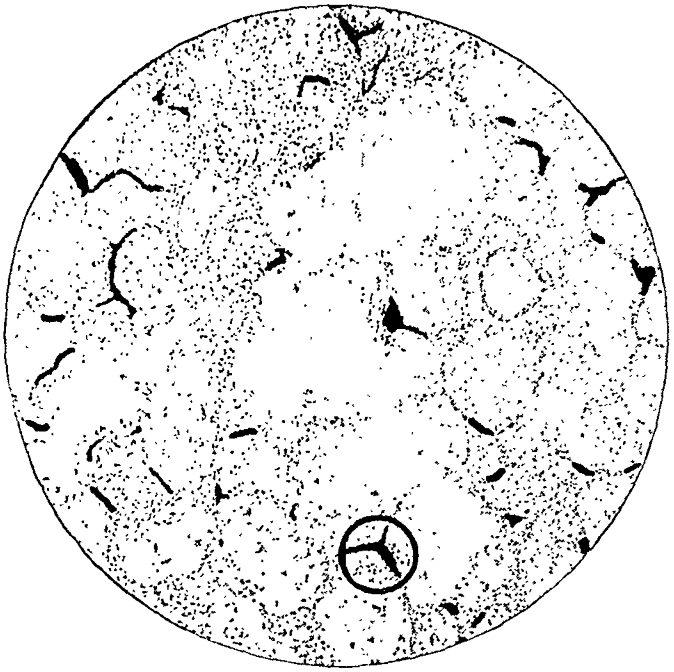

Fig. 2.—The necrotic regions are made black with india ink to show their number and the amount of the interalveolar capillary meshwork and alveolar wall involved; × about 60.

Although present in a few lungs seen in other postmortem examinations, the best examples of this disseminated necrosis were found in some of the small regions of pneumonia in the lower lobe of the right lung (weight 1,350 gm.) of a soldier, aged 23, who became acutely ill after having had a slight cold for six days and who died four days later.

Figure 1 represents about 7 sq. mm. (magnification 14 diamaters) of a section in which the pathologic condition is chiefly edema. Scarcely any alveoli are jammed full of red blood cells. A little fibrin is peripherally disposed in the air sacs, and a little exudate of leukocytes is present in most of them, but at no place is there any highly cellular consolidation. The pale oblong space jutting in from the lower half of the left edge is a hugely dilated perivascular lymph channel. Part of the circle in the lower right-hand corner represents the region shown in Figure 2 (magnification 60 diameters); in this the portions of the interalveolar meshwork of capillaries which are necrotic have been made black with india ink, as accurately as possible. The region included in the circle near the lower margin is shown in Figure 3 (magnification 470 diameters).

The changes that are illustrated by these figures, such as fragmentation of nuclei and "nuclear dust" in tissue taken a few hours after death, and, moreover, in which there is no suggestion of postmortem change; a

[1] LeCount, E. R.: The Pathologic Anatomy of Influenzal Bronchopneumonia, J. A. M. A. 72:650 (March 1) 1919.

widely disseminated, sharply outlined focal necrosis of the minute blood vessels and with so little of alteration except edema in the lung tissue, goes a long way toward at least suggesting an explanation for a number of things, such as the early hemorrhages in the lung, the escape of such large amounts of fluid from the blood into the lungs and from them into the pleural cavities, also the "button-like" firm peripherally located regions of consolidation compared by many observers to hemorrhagic infarcts.

They also suggest that the disease if not very early a systemic infection may become so later, because the nature of these lesions is best explained by embolism. In such sections as these no organisms other than those commonly present have been found.

CONCLUSION

In conclusion it may be well to emphasize that the 7 sq. mm. of Figure 1 is but part of a section, and that the necrotic regions represented by india ink in Figure 2 may be found not only in all parts of the 7 sq. mm. of Figure 1, but also in all parts of the section containing the 7 sq. mm., and in other sections as well; also, as stated, in sections of some of the other lungs examined. It may well be that such discrete necroses as these, with so little of other change except edema, represent a phase of the disease which is of short duration.

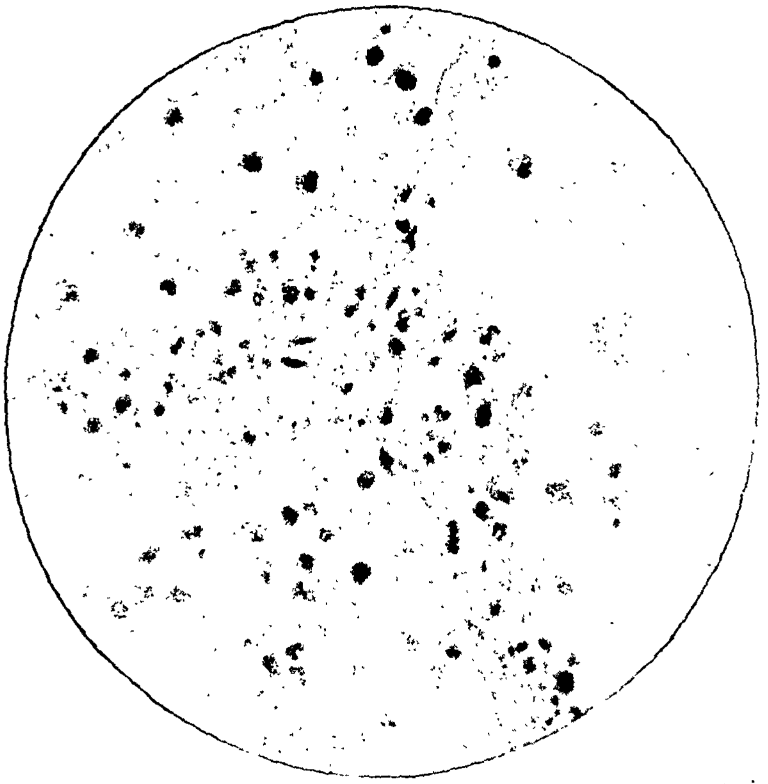

Fig. 3.—No red blood corpuscles or very few are present in the necrotic places, more commonly at junctions of adjacent alveoli, and their walls are replaced by leukocytes, fragmented nuclei and fibrin. The capillary meshwork is continued at the ends of these necroic regions and the blood for the channels and circulation are interrupted. circulates in them as usual; × about 470.

Influenza has been compared with the exanthematic fevers such as measles. Prodromal engorgement of the conjunctival blood vessels is referred to by many observers,[2] also the early appearance of lividity of the pharynx, described as a red fringe or crescent bordering the hard palate, with minute hemorrhages and a papulovesicular rash in the livid mucosa (Alexander). Moreover, Oberndörfer[3] has defined the disease as a bacteriemia with localization of the virus in the pulmonary blood vessels and secondary infection of the lung tissue so involved. For the foregoing reasons it has seemed best to attempt some description of these necroses at this time.

STUDIES IN STREPTOCOCCIC INFECTIONS AT CAMP CUSTER, MICHIGAN

WITH SPECIAL REFERENCE TO INFLUENZA AND OTHER ANTECEDENT INFECTIONS

WYNDHAM B. BLANTON, M.D. (Richmond, Va.)
Captain, M. C., U. S. Army, Chief of Laboratory Service

CHARLES W. BURHANS, M.D. (Cleveland)
Captain, M. C., U. S. Army

OLIVER W. HUNTER (Manhattan, Kan.)
Second Lieutenant, S. C., U. S. Army

CAMP CUSTER, BATTLE CREEK, MICH.

Sixty-five per cent. of the deaths from acute infections occurring in this camp since its establishment and coming to necropsy have been due to the streptococcus. If the month of October, 1918, is excluded, when influenza was epidemic here, the streptococcus has been responsible for 75 per cent. of the fatal acute infections. For more than a year the attention of this hospital has been focused on the diseases caused by this extremely prevalent and virulent organism, and the facts which this experience has brought to light are here assembled.

TABLE 1.—BACTERIOLOGIC FINDINGS IN ACUTE INFECTIONS AT NECROPSY

	Deaths from Streptococci		No. Deaths from	
	Number	Per Cent.	Pneumococci	Other Acute Infections
Prior to the influenza epidemic..	37	70	10	6
During the influenza epidemic....	142	62	78	8
Since the influenza epidemic.....	26	86	1	3
Total	205	65	89	17

Reference to the accompanying chart will show the total incidence of streptococcus, compared to its closest competitor, the pneumococcus. The incidence of measles has also been charted. It will be seen that streptococci, except for a period in the spring and summer of 1918, have always outnumbered pneumococci. During the summer months, living conditions peculiar to military establishments are less productive of carriers, and cross infections by such organisms as hemolytic streptococci appear to be less frequent. Certainly during the summer months the relative incidence of these two infections more nearly approached what is commonly observed in civil life.

This camp was several months old before streptococcic infections began to appear. It was in January, 1918, that acutely fulminating pleurisies appeared associated with bronchopneumonia, terminating fatally in a high percentage of cases. Irons and Marine[1] were among the first to recognize the relation of these fatal infections to such antecedent factors as exposure and fatigue, or to other diseases, such as measles. Throughout the winter, streptococcic invasions continued to occur with such frequency and astonishing virulence as to awaken the greatest concern. However, with the advent of spring they gradually lessened, and virtually disappeared during the summer. Coincident with the appearance of influenza in October, 1918, the streptococcus again came forward as the cardinal cause of death, regularly manifesting itself in a bronchopneumonia. During the epidemic, 674 deaths occurred, about two thirds of which were due to the streptococcus. During the four months since the epidemic, streptococci have occurred with even greater relative frequency, twenty-six out of the last thirty cases of acute infections coming to necropsy having had a fatal issue owing to the presence of this organism. During February, 1919, eighty-four infected wounds have shown hemolytic streptococci. Many cases of otitis media and numerous very severe mastoid infections have also appeared. Indeed, the greatest variety of localization has been encountered. This has been noted following the crest of each new wave of acute infections.

OCCURRENCE OF STREPTOCOCCI AS SECONDARY INFECTIONS

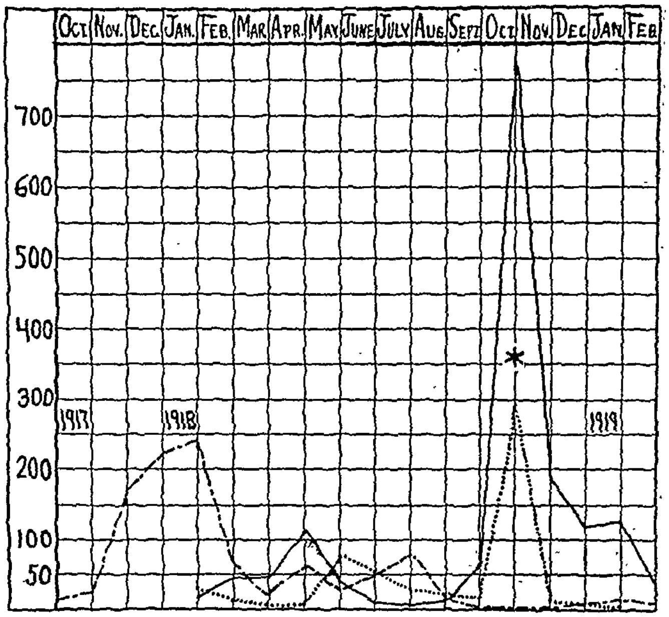
Streptococci have occurred at Camp Custer chiefly as secondary infections. Two methods of invasion have to be considered:

1. A very sudden and severe antecedent infection may so lower resistance that the ordinary mouth organisms gain admittance to the body with ease and in great numbers. An extensive example of this mode of secondary invasion was seen in the influenza epidemic. In this epidemic, death was invariably the result of a bronchopneumonia. These bronchopneumonias were not produced by a single organism, as would have been the case had a highly virulent and contagious organism been abroad at the time. On the contrary, they appeared to be caused in each case by the organism which the individual happened to have predominating in his mouth at the time, no matter whether that was streptococcus, pneumococcus, staphylococcus or Pfeiffer's bacillus. The very suddenness with which the epidemic came, attended immediately by secondary pneumonias, enforces the same idea. During this epidemic, *Streptococcus hemolyticus* caused only a few more deaths than the nonhemolytic strains. Pneumococci were recovered in about half as many cases as streptococci, and only a few staphylococci and Pfeiffer's bacilli were found. However, with the advance of the epidemic, *Streptococcus hemolyticus* became more and more prominent, while other causative organisms were encountered less frequently. *Streptococcus hemolyticus* appeared to gather virulence and prevalence more rapidly than the other organisms encountered earlier.

2. In other cases the virulence of the streptococcus appears to be the principal determining factor. Such cases were encountered in the early months of 1918, to which we have already referred. At that time masks were not generally used throughout the hospital, and the cubicle system was not in vogue in all wards. Superinfection was therefore much more of a possibility than at the later period, such as during the influenza epidemic. The fact that for several months antedating the appearance of these acute streptococcus infections many cases of measles and quite a number of so-called "colds" had been admitted to the base hospital with almost negligible complications speaks for a more important factor than the antecedent infection. This was evidently furnished in the virulent strains of streptococci brought into this camp by new troops arriving in January, 1918. The fact that many of these new arrivals were ill on reaching camp was brought out in the empyema report[2] of this camp covering that period.

FACTORS IN THE INCIDENCE OF STREPTOCOCCIC INFECTIONS

There are undoubtedly many contributory factors making for streptococcic invasions. An analysis of the records of 2,149 cases of pneumonia following influenza was undertaken in an effort to bring to light some of these factors. The majority of these pneumonias were, as we have said, streptococcic in origin.



Total incidence of streptococcus and pneumococcus infections charted by months, Camp Custer, Mich., September, 1917, to March, 1919: continuous line, streptococcus; broken line, pneumococcus; dotted line, measles; star, influenza epidemic.

It was not possible to determine what proportion of troops in this camp came from large cities, small towns, and rural districts, respectively. But it was possible to learn the relative incidence of influenza in troops falling into these three classes. From these figures the proportion of influenza that was complicated by pneumonia and terminated fatally was obtainable. The results of this analysis are set forth in Table 2. The percentage of pneumonia following influenza was more than twice as high in troops from rural districts as in troops from small towns or cities. *This difference did not* seem to exist as far as influenza alone was concerned. In other words, the existence of a previously established immunity was *not evident in the case of influenza*, but was evident in respect to secondary infections such as pneumonia. Troops from rural districts were probably no more susceptible to influenza than any other troops, but twice as high a percentage from rural districts died because they were twice as susceptible to secondary invaders, particularly to the streptococcus. After pneumonia developed, the death rate was approximately the same.

---

[2] Review of War Surgery and Medicine, 1, No. 9, 1918.

Out of 39,675 troops stationed at this camp at the time of the influenza epidemic, approximately 23,000 had seen less than two months' service, or about 60 per cent. of the command was composed of new troops. Table 3 illustrates the greater susceptibility of new troops to both the initial and the secondary infections, and the attendant high mortality in such troops. The physical strain incident to change from civilian to army life which new troops have to undergo before they become acclimated probably accounts in part for the increased susceptibility to infections. As Irons and Marine pointed out, the same factors were probably operative during the winter months of 1918. Unaccustomed to long hikes, exposure and the undoubted physiologic shock of vaccination, new troops show less resistance to all acute infections. Opie and his collaborators found the same thing to be true at Camp Pike.[3] Wallis collected even more striking figures at Camp Lee.[4] But in addition to all these possible factors, there seems to be still some intangible but evident difference between new and old troops, on account of which the latter become less susceptible to disease when both classes are under the same conditions.

That organisms gain admission to the body of the host owing to disturbances in the normal balance of resistance and virulence is well known. This method of invasion has already been referred to in discussing postinfluenzal pneumonia, and needs no further amplification. But the question of contact infection remains to be considered. Table 4 serves to illustrate the effect of contact on the incidence of secondary pneumonia. This point is forcibly impressed after comparing the figures for medical officers and nurses with those for line officers. The high incidence of infection among those in the hospital in contact with the disease during the influenza epidemic has another explanation in the extreme tax on physical endurance put on every one during those days. We have no ready explanation for the low incidence of influenza and pneumonia in hospital corps men, other than the extreme care taken to protect them by means of instruction, masks, cubicling in barracks and mess table screens. The possibly less intimate contact with patients as compared to physicians and nurses may also offer some explanation. Further, men were instructed to report sick on first symptoms of indisposition, and thus serious complications were, for the most part, avoided. In addition, they were old troops, and had been hardened and kept fit by daily drill.

TABLE 2.—COMPARISON OF THE INCIDENCE OF SECONDARY PNEUMONIA IN TROOPS FROM THE CITY AND COUNTRY: BASED ON 8,788 CASES OF INFLUENZA, COMPLICATED BY 2,149 PNEUMONIAS

Source	Per Cent. of Total Influenzas	Per Cent. of Total Pneumonias	Per Cent. Influenzas Developing Pneumonia	Pneumonia Case Fatality per Cent.	Influenza Case Fatality per Cent.
From cities of over 10,000	27.6	18.2	16.0	28.5	4.5
From cities and towns under 10,000	33.3	21.9	16.1	30.9	4.9
From rural districts*	39.1	59.9	37.4	28.9	10.8

* Patients whose occupation was farming or whose address was R. F. D.

Pneumonia was twice as frequent in army nurses as in civilian nurses. The latter were a part of the nursing personnel only for the emergency period of the epidemic. In spite of the utmost care exercised to see that every one went to bed as soon as sick, many army nurses were found ill who had given no heed to warnings and remained on duty through several days of sickness.

TABLE 3.—THE EFFECT OF LENGTH OF SERVICE ON THE INCIDENCE OF INFLUENZA AND SECONDARY PNEUMONIA

	Length of Service		
	One Month or Under	Two Months	Over Two Months
Approximate strength*	8,598	14,857	16,220
Total number of influenza cases	3,184	2,834	3,299
Per cent. of command developing influenza	37	19	20.3
Total number of pneumonia cases	813	645	691
Per cent. of command developing pneumonia	9.4	4.3	4.2
Per cent. of influenza developing pneumonia	25.5	22.7	20.9
Deaths:			
Total	431		203
Per cent. of influenza	7.1		6.1
Per cent. of pneumonia	29.5		29.2
Per cent. of command	1.8		1.2

* Based on weekly headquarters report of mean strength of command.

It was noted during the influenza epidemic that, whereas pneumococci occurred as infecting agents in about one third of the early cases, they gradually gave place to hemolytic streptococci and eventually disappeared entirely. The pneumococcus has been isolated only three times as the cause of disease in a period of two months (January and February, 1919). What led to the disappearance of the pneumococci we do not know. Where did so many hemolytic streptococci come from? Droplet infection as a cause of secondary pneumonia was negligible during the period of prevalent influenza. Practically every bed was cubicled, and everybody wore masks. Moreover, we have repeatedly demonstrated the effectiveness of the mask, as used in this hospital, by coughing into blood agar plates held at various distances from the mouth, with and without masks. Weaver,[5] in a series of extensive experiments, has shown very conclusively the efficiency of the mask in preventing droplet infection. In this camp special care in the boiling of mess equipment has apparently been effective in stamping out small epidemics of tonsillitis in line organizations. Lynch and Cumming[6] have presented statistics to show the reduced incidence of influenza in organizations whose mess equipment was properly sterilized after using. Even with the use of masks there is recognized carelessness in the washing of hands. Undoubtedly the hand to mouth route accounts for the spread of at least some of these infections.

TABLE 4.—THE INFLUENCE OF CONTACT ON THE INCIDENCE OF INFLUENZA AND SECONDARY PNEUMONIA

		Influenza		Pneumonia		Deaths	
Organization	Strength	No.	%	No.	%	No.	%
Total in camp	39,675	9,317	23.4	2,149	5.4	674	1.7
All medical and dental officers	164	42	25.6	9	5.5	2	1.2
All other officers	1,436	95	6.6	22	1.4	0	0.0
Ward men in base hospital	120	14	11.7	3	2.5	1	0.8
Other corps men in base hosp.	455	57	12.0	12	2.6	7	1.5
Army nurses	144	44	30.6	15	10.4	2	1.4
Civilian nurses	121	44	36.3	8	6.6	1	0.8

LOCALIZATION OF STREPTOCOCCI

There were recently reported a number of wound infections in a clean surgical ward. Cultures were made from the throats and wounds of all patients in that ward. It was found that all of those patients whose wounds were infected by hemolytic streptococci harbored numbers of the same organisms in their mouths, whereas those patients whose wounds were not infected did not have this organism in their mouths at the time. Transfer of organisms from mouth to wound by means of the hands can be considered possible in some cases. A further explanation may be found in the probable occurrence of a transient symptomless bacteremia with portal of entry in the throat and localization at the point of injured tissue in the wound. The fact that blood cultures in all these cases were negative does not exclude the possibility of this route of infection of clean wounds. In one instance a clean abdominal wound had healed and the patient was being prepared for discharge. This wound suddenly broke down, and hemolytic streptococci were recovered. The same organism was also found in the patient's throat.

In another instance, hemolytic streptococci were recovered in pure culture from a small abscess that developed in the arm at the site of an antipneumococcus vaccine injection. This soldier was a carrier of large numbers of hemolytic streptococci in his throat at the time.

TABLE 5.—STREPTOCOCCI IN THROATS IN HEALTH AND IN DISEASE

Condition of Throats	Number of Culture	Total Cultures					
		Showing Streptococci		Showing Hemolytic Streptococci		Having a Growth of 50% Hemolytic Streptococci	
		No.	%	No.	%	No.	%
Normal throats, camp organizations........	3,299	3,044	92.2	1,469	44.5	374	11.4
Normal throats, laboratory det.	1,662	1,371	82.4	741	44.5	169	10.1
Patients with upper respiratory infec.	1,069	1,024	96.1	833	77.9	511	47.6
Patients convalescent from pneumonia.....	203	182	88.6	141	69.4	87	42.8
Patients with empyema...............	739	596	80.6	465	60.2	223	30.1

Cultures on blood agar plates to the number of 6,972 have been made from the throats of both sick and normal individuals. These cultures were taken during a period of several months, and included patients in the hospital and members of other camp organizations. The principal fact brought out was that many normal as well as ill persons are carriers of hemolytic streptococci, and that the significant observation lies not merely in the presence of the hemolytic streptococcus, but rather in knowing in what numbers it occurs. For this reason an endeavor has been made to ascertain the percentage of throats showing on culture over 50 per cent. of hemolytic streptococci. This estimation was made in each case, after a rough determination of the total number of colonies growing on blood agar plates, by calculating the percentage of hemolyzing colonies with streptococcic characteristics. The importance of this distinction was made apparent in the summer of 1918, when the small number of hemolyzing colonies on plates was striking, whereas during the fall and winter it has been not unusual to find from 60 to 80 per cent. of hemolytic streptococci in so-called normal mouths.

In our experience, hemolytic streptococci are rarely found in the nose. From the posterior pharyngeal wall and sputum they may be recovered in a considerable number of cases. The tonsil plays the most important rôle in harboring this organism. Many careful cultures from the tonsils of normal persons not particularly exposed to patients ill with streptococcic infections have shown hemolytic streptococci in 90 per cent. of cases. On the other hand, we have only occasionally found them in the throats of those who have had their tonsils removed. Hemolytic streptococci have been recovered from the depths of 80 per cent. of tonsils examined after operative removal. These results are in line with those of Nichols and Bryan.[7] In some cases we were surprised to find hemolytic streptococci in throats from which tonsils were said to have been removed. These patients were examined by a throat specialist, and in every instance some remaining tonsillar tissue was found.

LESIONS PRODUCED BY STREPTOCOCCI

Lungs. — Sixty-eight per cent. of all streptococci recovered in the last fourteen months were from patients with acute pulmonary infections. In these cases bronchopneumonia has been an invariable finding. The organism was identified either from the lung at necropsy or in the sputum during life. Moreover, 70 per cent. of all the pneumonias occurring in this camp have been of streptococcic origin.

Pleura.—Likewise by far the greatest number of pleural infections have been produced by the streptococcus. Coincident with the bronchopneumonias of the winter of 1918, very acute and fatal suppurative pleurisies were encountered. In many instances it was impossible to say which process preceded the other. Strikingly different were the pleural infections encountered in the wake of the influenza epidemic. The proportion of all pneumonias developing fluid in the chest was nine times as great during January, February, March and April as in the month of October, 1918. Pneumonia definitely preceded the appearance of fluid in the latter group of cases. Unlike also were these two periods in the course and outcome of their pleural infections. Pleuritis following influenza ran a much less violent course and was accompanied by a lower mortality. It should be noted, however, that the average duration of life in fatal cases during the epidemic was from six to ten days, and many patients died in from one to three days after the onset of pneumonia, a period of time too short to allow of the development of lesions such as empyema, which ordinarily require a longer time to become clinically evident.

Blood.—The infrequency of septicemia accompanying other localizations of streptococci in the body has frequently invited remark. On many occasions, organisms have been recovered from the blood at necropsy which repeated cultures had failed to reveal during life. An exception to this has been found in cases of mastoiditis. In this condition, 30 per cent. of blood cultures have yielded *Streptococcus hemolyticus.* Recently several strains of hemolytic streptococci have been recovered from blood cultures which grew distinctly better at low oxygen tension. Without the routine use of anaerobic plates, one of these organisms would never have been isolated.

SEROLOGIC CURE (?) IN THE LIGHT OF INCREASINGLY SENSITIVE WASSERMANN TESTS

UDO J. WILE, A.B., M.D.
Professor of Dermatology and Syphilology, University of Michigan Medical School

AND

CLYDE K. HASLEY, A.B., M.D.
Instructor in Dermatology and Syphilology, University of Michigan Medical School

ANN ARBOR, MICH.

Among recent modifications of the Wassermann reaction which are accepted today as adding to the refinement and delicacy of the test are the employment of cholesterin-sensitive antigens and the fixation of the complement under conditions of cold rather than as was originally carried out at 37 C. in the thermostat. In 1912-1913, McNeil,[1] employing comparative tests with incubation at 37 C. and at ice-box temperature, showed an increase of more than 10 per cent. in delicacy of the low temperature over the high. These results were substantiated by Coca and L'Esperance,[2] and in a large series of cases more recently by Smith and MacNeal.[3]

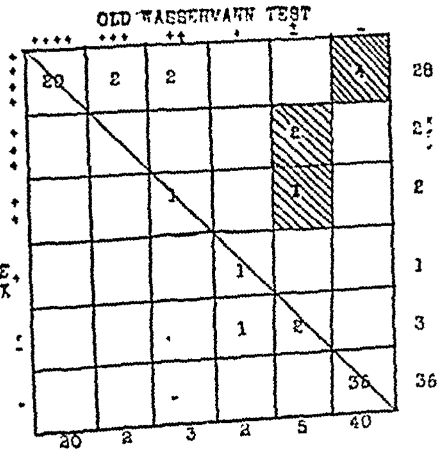

Chart 1.—Primary syphilis: Wassermann reaction in seventy-two cases on admission; shaded figures (seven cases) would have passed as negative with old Wassermann test.

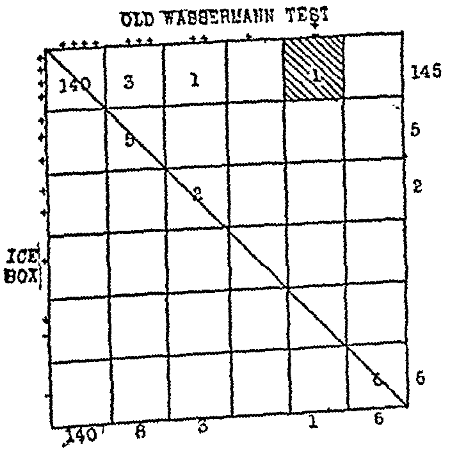

Chart 2.—Secondary syphilis: Wassermann reaction in 158 cases on admission; shaded figure (one case) would have passed as negative with old Wassermann test.

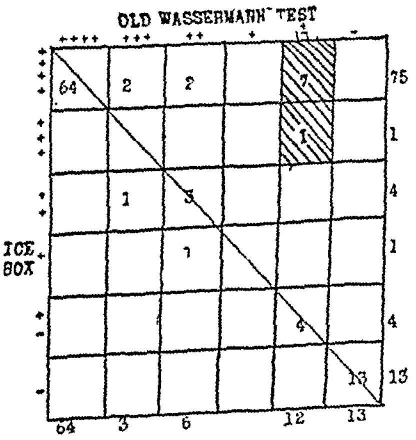

Chart 3.—Tertiary syphilis: Wassermann reaction in ninety-eight cases on admission; shaded figures (eight cases) would have passed as negative with old Wassermann test.

These authors conclude that the use of simple alcoholic antigen with the first incubation carried out in the ice-box is more sensitive in the detection of syphilis than the use of cholesterin-reinforced antigen with incubation at 37 C. or simple alcoholic antigen at 37 C.

During the past eighteen months, comparative tests have been made in the University Hospital on syphilitic and controlled serums with the use of the old Wassermann test, employing cholesterin-sensitive antigens with incubation at 37 C., and the same antigen with incubation at ice-box temperature for sixteen hours. The number of tests carried out under these conditions goes into the thousands. For the purpose of this study, however, we have selected 459 cases of syphilis in all stages, in which, on entrance, a clinical diagnosis was made and in which both tests were done. Of this number, all may be used for the purpose of studying the comparative delicacy of the two tests during the various stages of the disease. In Charts 1, 2, 3 and 4 are tabulated comparative results of the two tests.

In primary syphilis, of which seventy-two cases were admitted, it will be seen by consulting the charts that seven would wholly have been missed if dependence had been placed on the old test. Equally uniform findings in both tests are noted in twenty, four plus positives and thirty-six negatives. Of interest in this group, therefore, are the seven cases in which antibodies were demonstrated earlier in the ice-box than by the older test.

Under secondary syphilis, with lesions in full bloom, there were studied 158 cases (Chart 2). As might be expected, in this group there was *great uniformity* in the findings; there was only one case which reacted strongly positive to the ice-box and doubtful to the old test.

Under tertiary syphilis, there were studied ninety-eight cases. In this group (Chart 3) it is noticed that eight cases gave a doubtful reaction with the old test and therefore would probably have been passed as negative, whereas they are strongly positive with the ice-box test. Thirteen cases of this group were uniformly negative in both, and sixty-four were positive to the same degree in both.

One hundred and thirty-one cases of syphilis in the latent period are illustrated in Chart 4. It is interesting to note that in this group of cases, seven would have been passed as either negative or cured cases on the basis of the old test, while giving a strongly positive reaction with the more sensitive ice-box test. In this chart is also illustrated a degree of sensitiveness in twenty-eight cases in favor of the cold method.

To sum up, therefore: Of 459 cases of syphilis in all stages, incubation of the serums in the cold was found to be uniformly more sensitive than incubation at 37 C., and of this group of cases twenty-two, or about 5 per cent., would have been deemed nonsyphilitic or cured, if the diagnosis had depended on the Wassermann test as carried out in the thermostat.

Turning now to the cases which we have been able to observe over the period of eighteen months, there are available for close scrutiny only thirty-nine in which we are satisfied that intensive therapy was carried out, and in which repeated tests were made. The treatment instituted in all these cases has been in the form of courses of arsphenamin or neo-arsphenamin, no patient having received less than six injections and

3. Smith, J. W., Jr., and MacNeal, W. J.: J. Immunol. **2**: 75 (Dec.) 1916.

most of those under discussion here having received two such courses, together with intensive mercurialization over a greater portion of the period of observation with inunctions or injections.

From a study of Charts 5 and 6 it will be noted that of thirteen cases of secondary syphilis on admission, in only one case is any difference to be noted in the reaction of the serum in both tests. After treatment, however, it will be noted (Chart 6) that eight cases became negative or doubtful and have remained so with the old test while still giving a strongly positive reaction to the ice-box test.

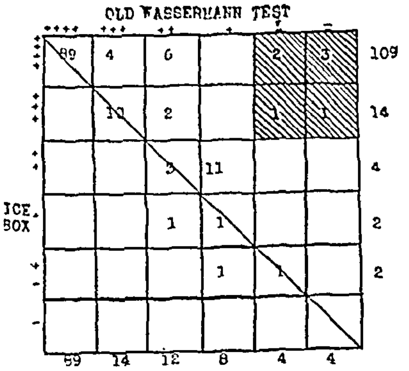

Chart 4.—Latent syphilis: Wassermann reaction in 131 cases on admission; shaded figures (seven cases) would have passed as negative with old Wassermann test.

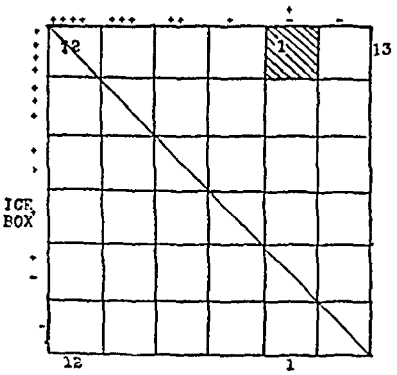

Chart 5.—Thirteen treated cases of secondary syphilis on admission: Shaded figure (one case) would have been considered doubtful on admission on basis of old Wassermann test.

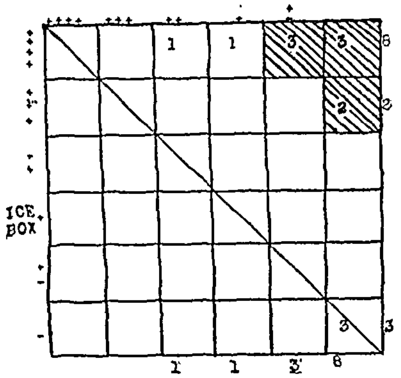

Chart 6.—Thirteen treated cases of secondary syphilis after treatment: Shaded figures (eight cases) would have been considered as cured on basis of old Wassermann test.

In the group of tertiary syphilis cases studied over this period in which treatment has been instituted and the patients have been under careful and frequent observation, there are sixteen cases. Of these (Chart 7), on admission four, by reason of negative tests with the old Wassermann, might well have escaped recognition. These four gave strongly positive reactions in the ice-box. After treatment, however (Chart 8), a great degree of divergence is noted in these cases. Nine became negative or doubtful and would thus be considered as progressing toward serologic cure and by some perhaps cured, whereas all of these still give strongly positive reactions in the ice-box test. A further study of the chart reveals on the part of the five other cases a gradual approach toward the negative phase with the old test, with little or no difference in the intensity of the reaction with the ice-box. Two cases became uniformly negative with both tests.

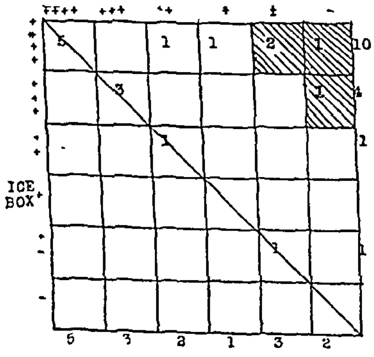

Chart 7.—Sixteen treated cases of tertiary syphilis on admission: Shaded figures (four cases) would have been considered doubtful on admission on basis of old Wassermann test.

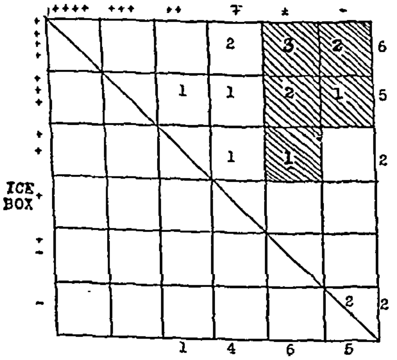

Chart 8.—Sixteen cases of tertiary syphilis after treatment: Shaded figures (nine cases) would be considered as cured on basis of old Wassermann test.

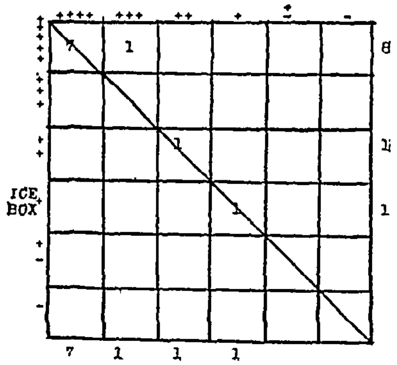

Chart 9.—Ten treated cases of latent syphilis on admission: uniform findings in both tests.

Of the group of latent cases, only ten were available as having been assiduously treated and frequently tested over the period of observation. Of these, on admission (Chart 9) a uniform finding is noted by both tests in all cases. After treatment, however (Chart 10), it will be noted that five cases became negative or doubtful with the old test and thus might have been considered as cured or approaching serologic cure, whereas the ice-box test revealed them as still strongly positive. This chart illustrates, as does Chart 8, the gradual diminution of sensitiveness in the old test in the remaining cases as against practically constant, intensely positive, reactions as shown by the ice-box test.

To sum up, therefore, it would appear to us that in a total of thirty-nine cases, treated over the period of eighteen months, only six cases have become serologically negative with the ice-box test, as against twenty-two, or more than 50 per cent., which became apparently negative with the old test.

The modern methods of carrying out the Wassermann reaction are today, under all conditions, far more sensitive than those which were used in the early days of serologic examination. Each year some refinement of the technic brings to light more and more positive cases which, under previous conditions, would have been negative, and it seems quite reasonable to us to predict that the last word on the subject is yet far off. It is even justifiable to assume that within a short time a test more sensitive than that carried out in the ice-box may be elaborated.

When one compares the relative sensitiveness of older tests with those employed today, and the ever increasing refinements, it becomes apparent that at best our laboratory methods are crude means to detect chemical and physicochemical changes taking place in the cells of the body after infection.

As a diagnostic aid, the positive Wassermann reaction still stands as our greatest aid and a tremendous step forward in the uncovering of syphilis. It has long been taught, and until recently we shared with others the belief, that the goal to be attained in the treatment of syphilis is the conversion from a positive to a negative phase in the blood test. We are fast being converted to the view that, excepting in the small group of early cases in which positive tests are never elicited and the cases are aborted, to attempt this end is, as it were, chasing a shadow.

Until more is known about the nature of this reaction, as to whether it is caused by antibodies or immune substances, it seems to us that there is equally less justification to attempt or to expect well established positive cases to become permanently negative.

We are convinced that in the presence of an intensive therapy, a positive test does not necessarily mean *living spirochetes and potential syphilis any more than* a positive tuberculin test in an individual who has had tuberculosis would indicate the presence of living tubercle bacilli.

With the ever increasing discrepancies reported with each refinement of the Wassermann test; with the ever increasing number of permanently positive cases, previously regarded negative, it appears to us that as a guide to therapeusis, the Wassermann reaction does not have a leg to stand on.

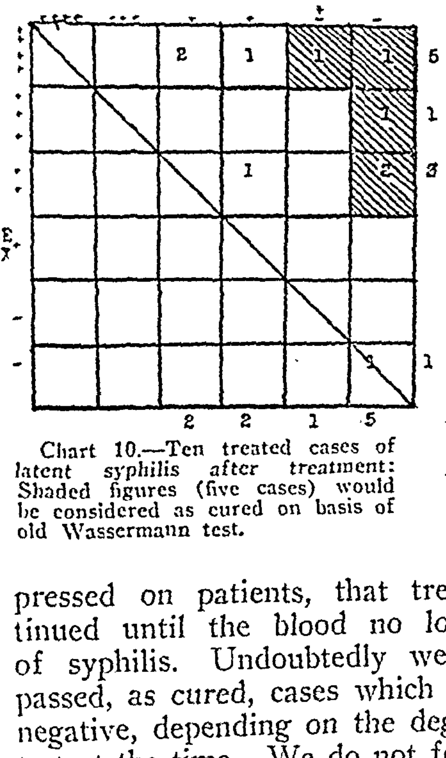

Chart 10.—Ten treated cases of latent syphilis after treatment: Shaded figures (five cases) would be considered as cured on basis of old Wassermann test.

We stand today, with regard to the criteria of the treatment and cure of syphilis, as did the syphilologists of the pre-Wassermann day.

Until recently we have taught, as have all others, and have impressed on patients, that treatment must be continued until the blood no longer shows evidences of syphilis. Undoubtedly we, as all others, have passed, as cured, cases which have been recorded as negative, depending on the degree of delicacy of the test at the time. We do not feel that these cases are necessarily not clinically cured, although modern tests would show many surely as positive.

Whatever intensive treatment has been directed toward the eradication of the Wassermann reaction has undoubtedly been well directed toward the eradication of the disease.

In the light of our real ignorance of the nature of the reaction, particularly in the interpretation of late persistent tests, we submit that serologic and clinical cure are not necessarily parallel. Energy of treatment directed toward the end of attempting to make a persistent positive react negatively may well be not only useless but misdirected.

The Laborer's Health.—On the health of the nation depends the efficiency of labor, and the economic value of the laborer is one of the arteries of commerce.—Arthur E. Holder.

SUGAR TOLERANCE IN CANCER*

G. L. ROHDENBURG, M.D.
ADOLPH BERNHARD, B.S.
AND
OTTO KREHBIEL, M.D.
NEW YORK

The insidious onset of a malignant tumor with the lack of positive evidence, in the majority of instances, until the case is far advanced, is perhaps the greatest difficulty in the way of a decided reduction in cancer mortality. Certain well established facts of cancer etiology may be briefly stated in order to explain the basis of the experiments of which this paper constitutes a preliminary report.

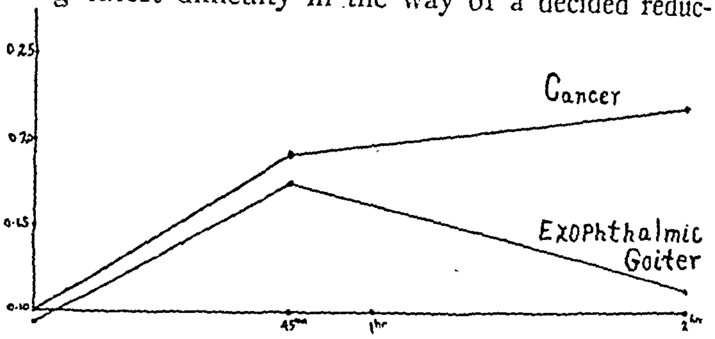

Chart 1.—Comparison of the curve of sugar tolerance in exophthalmic goiter and in cancer. *In this and in the subsequent charts the ordinates give the sugar percentages per hundred c.c. of blood, while the abscissas indicate the zero hour, forty-five minutes, and one and two hours, thereafter.*

Broadly speaking, the development of malignant tumors rather frequently follows irritation, though no irritant is specific. It is generally accepted that not every one exposed to the action of any given irritant develops a tumor. In other words, there is an apparent predisposition as well as an actual inciting irritant. Again, broadly speaking, since exact statements are not possible in the present state of our knowledge, this predisposition becomes more evident at a certain period in life, a period spoken of as the cancer age, and demonstrable in animals as well as man.[1] Not a few investigators have attributed cancer development to faulty function of the endocrine glands, one or the other gland being held responsible. So far there has been no positive evidence produced that will support this hypothesis. There are no specific lesions demonstrable in the endocrine glands of mice with spontaneous tumors[2] nor does extirpation or the feeding of one or more of these glands have any apparent influence on the rate of growth, infectivity, or immunity against animal tumors.[3]

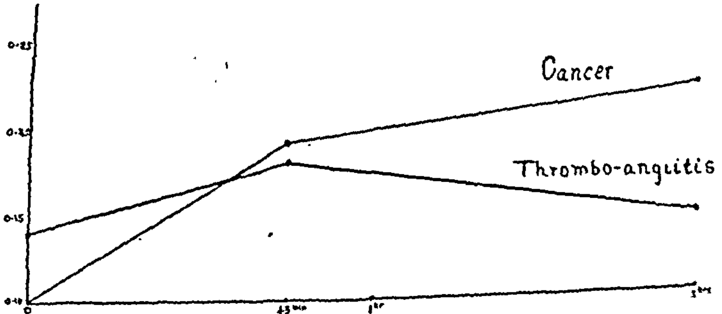

Chart 2.—Comparison of the curve of sugar tolerance in thrombo-angiitis and in cancer.

---

* From the Pathological Laboratories of the Lenox Hill Hospital.

[1] Murray: Proc. Roy. M. & Chir. Soc., Series B, 84:42, 1911-1912. Slye: J. Cancer Res. 1:479, 1916.

[2] Rohdenburg and Bullock: J. Med. Res. 33:147, 1915.

[3] Rohdenburg, Bullock and Johnson: Reports of George Crocker Special Research Fund 3:87, 1913.

Nevertheless, it is possible that there may be derangement of endocrine function not demonstrable by histologic or surgical technic. The functional activity of some of the endocrine glands can, to some extent, be measured by the sugar tolerance test first brought into clinical use by Jacobsen[4] in 1913. With this method Janney and Isaacson[5] have demonstrated that the removal of the thyroid in dogs is followed by a hypoglycemia. Other clinicians have applied the test in a variety of conditions, among which may be mentioned diabetes, nephritis, exophthalmic goiter, pituitary disease, myxodema and thrombo-angiitis obliterans. In some of these diseases typical curves of no inconsiderable value in diagnosis have been established though unfortunately not applied clinically with the frequency which the importance of the data so obtained warrants.

Following the method as outlined in a succeeding paragraph we have obtained values apparently constant in cancer, which may ultimately prove of value in diagnosis. It is for this reason that a preliminary report is made.

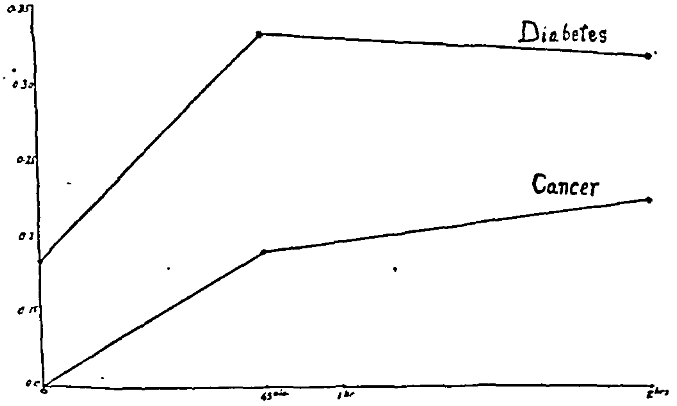

Chart 3.—Comparison of the curve in diabetes and in cancer. Note that the diabetic curve starts at a higher point and commences to fall at the second hour, whereas the cancer curve does not.

TECHNIC OF THE TEST

In the morning, after a night's fast, the individual is given either 100 gm. of anhydrous or 115 gm. of syrup glucose dissolved in 300 c.c. of tea or coffee without milk or sugar, care being taken that the glucose is all dissolved and that the patient takes the entire amount. Just before giving the glucose, and again forty-five minutes and two hours after its ingestion, blood is withdrawn and the amount of sugar in it is determined by the method of Lewis and Benedict as modified by Meyers. At the same time periods the urine is qualitatively examined for sugar by the method of Benedict.

The epinephrin method may also be employed by giving 1 c.c. of a 1 : 1,000 solution of epinephrin hydrochlorid subcutaneously instead of administering glucose. All other manipulations are identical with the glucose procedure.

The normal curve of sugar tolerance as well as the curve in some diseases other than cancer is graphically portrayed in Charts 1, 2, 3 and 4 and needs no amplification here.

The cancer curve in contrast to the curve observed in other diseases starts with a normal blood sugar, 100 mg. per hundred c.c. of blood; rapidly rises so that forty-five minutes after the ingestion of glucose 180 or even 200 mg. per hundred c.c. are present, and two hours after the glucose is ingested the blood sugar is either as high as at forty-five minutes or higher, reaching 288 mg., and in one instance 350 mg. per hundred c.c. of blood. The percentage of blood sugar gradually falls and approximates normal in from three to four hours after the ingestion of the glucose. The average of four curves in which specimens of blood were taken up to three hours is shown in Chart 5. This curve was present in our limited experience in twenty-four cases of carcinoma and one of sarcoma and does not occur in some forty cases of other diseases which we have examined. The curve covering the use of epinephrin instead of glucose is identical with the curve following the ingestion of glucose.

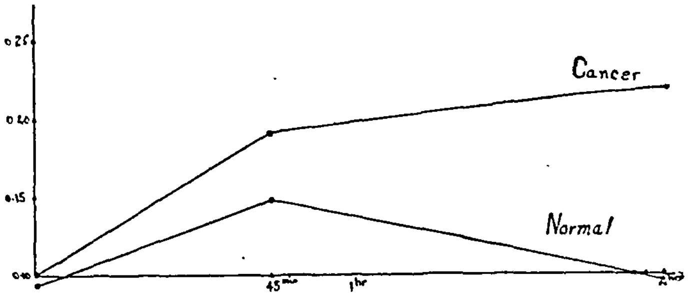

Chart 4.—Comparison of the cancer curve with the curve in normal individuals.

The sugar present in 100 c.c. of blood at the zero hour and at forty-five minutes and two hours after ingestion of glucose as it occurred in twelve cases is presented in the accompanying table. The sugar tolerance bears no relation to the location of the tumor, for primary carcinoma of the lung, carcinoma of the sigmoid, of the stomach, and of the breast and other organs, all give the same type of reaction.

Even with the high blood sugar present in these cases, sugar appeared in the urine rather infrequently, only 41 per cent. of the cancer cases showing sugar.

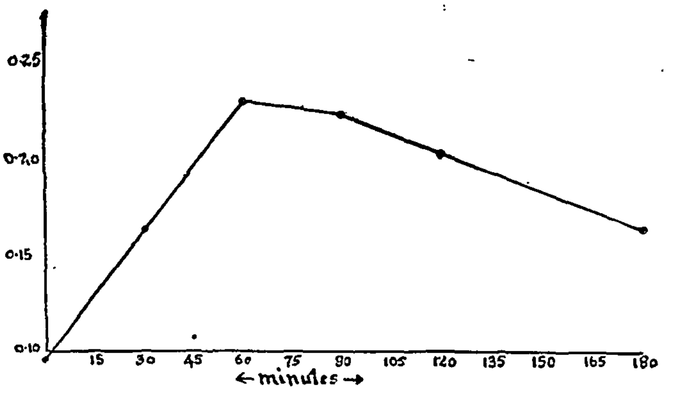

Chart 5.—Cancer curve based on four cases. The abscissas indicate the time period in minutes.

The value of the test is well shown in two of the cases of the series. Others could be quoted but these serve the purpose:

Case 1.—A man, aged 47, about three years before admission to the hospital had, without apparent reason, commenced to cough, having had no previous pneumonia, pleurisy, nor other pulmonary condition. This cough persisted. In one hospital a diagnosis of probable lung abscess was made, possibly because of the type of sputum and the accompanying temperature. This abscess was thought to be possibly of tuberculous nature, though this could not be positively asserted. He then went to a sanatorium for tuberculosis where the diagnosis of bronchiectasis was made. He was then referred to Dr. Willy Meyer for operation. An exploratory puncture of the supposed bronchiectasis was made and pus was found. Operation immediately followed puncture and a pus sac was drained. Previous to puncture, roentgenograms showed a thickened pleura. The sugar tolerance curve was characteristic of tumor. The patient survived operation three days. At necropsy an adenocarcinoma arising from the bronchial epithelium was found. The tumor measured approximately 5 cm. in diameter and partially compressed the bronchi of the right lung, causing aneurysmal dilatation of the bronchi.

[5] Janney, N. W., and Isaacson, V. I.: The Blood Sugar in Thyroid and Other Endocrine Diseases, Arch. Int. Med. 22: 160 (Aug.) 1918.

In contrast to this case, a second would appear to illustrate the value of a negative curve:

Case 2.—A woman, aged 55, gave a typical history of gastric carcinoma situated at the pylorus. A roentgenogram disclosed almost complete obstruction at the pylorus and according to the roentgenographer a new growth was present extending from the pylorus toward the cardia, involving approximately the distal third of the stomach. Gastric analysis showed no hydrochloric acid. Lactic acid was present and Boas Oppler bacilli and blood were present. The sugar tolerance curve was that of a normal individual. After operation the blood gave a Wassermann + + + +. At operation, the entire pylorus, as well as the involved portion of the stomach wall, was resected. Microscopic examination failed to show any evidence of cancer, but did show a typical gumma and the perivascular round-cell infiltration of syphilis. Spirochetes were not demonstrable.

SUGAR PRESENT AT VARIOUS TIME PERIODS BEFORE AND AFTER INGESTION OF GLUCOSE

We prefer for the present not to theorize on the etiologic significance of the phenomenon so far observed; the possibilities are numerous, and theoretically one explanation is as good as another, nor shall we at this time venture an explanation of the mechanism of the occurrence, contenting ourselves rather with recording the phenomenon so that repetition in other hands than ours may more rapidly prove or disprove its value as a diagnostic test.

Defective Development of the Blood.—Pittaluga's term, "hemodystrophies," has been widely adopted to indicate defective formation of blood and the evils resulting therefrom. The biochemical alterations may predominate over the histopathologic, and there may be a more or less accentuated neuropathic factor, direct or indirect, through the mediation of the glands of internal secretion. Hereditary or familial factors may intervene directly or indirectly. Purpura, hemophilia, hemolytic jaundice, hemoglobinuria and the hemorrhagic diathesis can all be classed in the four main groups of the hemodystrophies: those with a hemorrhagic diathesis, with a tendency to polycythemia, to chlorosis, and the diathesis showing a tendency to eosinophilia. As he describes in the *Siglo Medico*, Nov. 16 and 23, 1918, pp. 939 and 956, these hemodystrophies reveal an intimate connection between the blood-producing organs and the endocrine system, and show the important part played by heredity.

THE NOSTRUM AND THE PUBLIC HEALTH *

ARTHUR J. CRAMP, M.D.
Director of Propaganda for Reform Department, The Journal of the American Medical Association
CHICAGO

Broadly speaking, the nostrum belongs in one of two general classes; one class comprises those unscientific mixtures that are advertised primarily to the medical profession, and first reach the public by way of the prescription; the other class includes those mixtures that are sold direct to the public. Nostrums in the first class are sometimes spoken of as "proprietaries"; those in the second class are colloquially known as "patent medicines." The public suffers from both classes, the only difference being that in the case of the former the physician has to share the responsibility with the nostrum exploiter. There is no clearly defined line of demarkation between these two classes. Many of the "patent medicines" of today were the "proprietaries" of yesterday. Shrewd manufacturers—or, more correctly, exploiters, for many of these products are not manufactured by those that sell them—discovered years ago that one of the least expensive methods of introducing a nostrum to the public was by way of the medical profession. After the profession had been widely circularized and much space bought in the advertising pages of medical journals of a certain type; after uncritical or unthinking physicians had prescribed the products (of course in the "original package" with the name blown in the bottle or a monogram stamped on the tablet); after the patient had learned with disgust that his physician had merely prescribed a "patent medicine" that could more cheaply have been purchased direct—then the one-time "proprietary" threw off its "ethical" mask and became frankly a "patent medicine." Such has been the genesis of many a "patent medicine" on the market today. Others, less deviously, have gone directly to the public at the outset.

FEW, IF ANY, REAL PATENT MEDICINES

The present paper deals with the "patent medicine" evil. Correctly speaking, there are practically no true patent medicines on the market; first, because few if any of the products of this type could be patented, and second, because patency or openness is the last thing the average "patent medicine" seller wants. Mystery and secrecy are his great assets. A product to be patentable must, according to the law—not always enforced, by the way—represent something new and useful; and this requirement of the patent law rules out the "patent medicine." A patent when granted gives the owner a legal monopoly on his product for seventeen years, after which time the product becomes public property. The "patent medicine" seller finds it easier and far more profitable to put together a simple mixture of drugs that represents nothing either new or useful, to which he gives a fancy name, and obtains a trade-mark on that name. The trade-mark gives him a perpetual monopoly to the name and places no restrictions on the composition of the product; nor, in the granting, is he required to give any information regarding its composition.

Thus "Winslow's Soothing Syrup" is still "Winslow's Soothing Syrup" in name, although the product on the market today bears but little resemblance to the original preparation sold under that name. As sold in the United States, it used to contain morphin and alcohol. As sold in Great Britain, potassium bromid was substituted for morphin because the British law requires the word "poison" on all "patent medicines" containing morphin. As the public in our country became aroused to the menace of the "baby killers," many drug stores refused to handle the Winslow preparation. Then the formula was changed, and changed again, so that today it contains neither morphin nor alcohol. But it is still "Winslow's Soothing Syrup."

---

* Read before the Chicago Medical Society, March 26, 1919.

THE FOOD AND DRUGS ACT

There has been a tendency during the past few years to assume that the federal Food and Drugs Act, commonly known as the Pure Food Law, effectively safeguards the public against the menace of the nostrum. Although this law has been in force for more than twelve years, there is still some misapprehension of its powers and limitations. First it should be realized that the law applies only to products that enter into interstate commerce; that is, those that are made in one state and sold in another. The federal Food and Drugs Act, for instance, exercises no control over the sale of "patent medicines" made in Illinois and sold anywhere within the state of Illinois, no matter how fraudulent the claims may be as to therapeutic effects, composition, or source of origin. The only way such preparations can be reached is under the state law.

It should also be realized that the Food and Drugs Act has no jurisdiction over claims made for foods or drugs except as those claims appear in or on the trade package. When the law was first passed, many "patent medicine" makers assumed that the term "label," as used in the Act, applied solely to the piece of paper pasted on the bottle. On this assumption, they modified the false claims they had been making on the label but continued to falsify in the circulars that were wrapped around the bottles. They soon found to their cost, however, that the courts gave a broader and more logical meaning to the word "label," including all of the printed matter in or on the trade package. The Food and Drugs Act exercises no control over statements that are published separate from the trade package—such as in newspapers, hand-bills, etc.

The Pure Food Law, as first enacted, prohibited, within the field it covers, "false or misleading" statements "in any particular." The officials entrusted with the enforcement of the Act assumed that this meant just what it said, and the majority of the "patent medicine" makers followed that assumption. Then the Supreme Court decided (in a divided opinion) that the law as it stood did not apply to statements regarding curative effects, but only to statements relative to composition and origin. This decision, of course, let down the bars immediately to the most obvious frauds. The more unscrupulous "patent medicine" makers care little about restrictions regarding the composition of their nostrums; they are much more concerned with being free under the law to make any assertion they see fit regarding the curative effect of their preparations. Then came the Sherley amendment to the Food and Drugs Act, which specifically prohibits "false and fraudulent" statements regarding the curative effects of medicines. It is to be noted that falsehood alone is not sufficient to secure conviction; the manufacturer must also be found guilty of deliberate intent to defraud.

Under the Food and Drugs Act, then, the manufacturer of a medicinal product may be declared guilty of misbranding, if the statements he makes (on the trade package) regarding the composition or the origin of his products are either "false or misleading"; he may also be found guilty of misbranding if the statements he makes (also, on the trade package) regarding the curative effects of his preparations are both "false and fraudulent."

Limiting the scope of the application of the law to the claims made on the package, is one of the fundamental weaknesses of the Food and Drugs Act. The law does not penalize the most outrageously false claims of any kind or description regarding "patent medicines," if those claims appear in newspaper advertisements, circulars, etc., that do not accompany the trade package. Yet it is the newspaper advertisement or the circular that sells the product, rather than the matter on the trade package, which the public does not see *until after it has purchased*. Thus we have the anomaly of a law which allows a manufacturer to lie to his heart's content in those avenues of publicity in which lying will be most profitable and do the maximum amount of harm, and restricts merely the statements he may make in his trade packages. This limitation in the Food and Drugs Act furnishes a sure way of determining with almost mathematical accuracy what statements regarding a "patent medicine" are false: From the claims made in the newspaper advertisements and circulars subtract those that are made in the trade package; the difference, you are justified in assuming, is falsehood!

LIMITED FORMULA DISCLOSURE

The "Pure Food Law" has one more power in protecting the public against the nostrum evil: It requires "patent medicine" sellers to declare (on the trade package only) the presence and amount of eleven drugs and their derivatives: alcohol, morphin, opium, cocain, heroin, alpha-eucain and beta-eucain, chloroform, cannabis indica, chloral hydrate and acetanilid. Further than this, the law permits the manufacturer to maintain complete secrecy regarding the composition of his preparation. He can, if he wishes, put in his product such deadly poisons as carbolic acid, arsenic, strychnin, prussic acid and aconite, and the public is none the wiser.

Many people have thought that the legend "Guaranteed under the Food and Drugs Act" that used to appear on bottles and cartons indicated that the federal government had in some way passed on the product and given it a clean bill of health. Nothing of the kind. Before the guarantee clause was abolished, any manufacturer could write into Washington and ask for a serial guarantee number, and Washington had no choice but to issue such a number—this, no matter whether the medicinal product was good, bad or indifferent, whether the claims under which it was sold were truthful or false or whether the drugs it contained were harmless or dangerous. All that the guarantee clause ever meant was that were the product sold in violation of the law, the person to whom the guarantee serial number had been issued would be held responsible, rather than the individual retailer. Some of the most outrageous swindles in the "patent medicine" world have been "Guaranteed under the Food and Drugs Act." Summed up, then, it may be said that the federal Food and Drugs Act gives the public a certain measure of protection. It permits the public to know the names and amounts of eleven drugs and their derivatives, and it limits the claims that can be made for these products, so far as such claims appear in or on the trade package.

THE PHYSICIAN'S INTEREST IN THE NOSTRUM EVIL

The nostrum evil is essentially a public health question, although, as in the case of many public health questions, it has its economic angle. The "patent medicine" maker persistently charges that the medical profession's opposition to "patent medicines" as now exploited is based on the assumption that the sale of such products diminishes the income of the physician. The charge, of course, is as malicious as the assumption is false. Next to the "patent medicine" men and the newspapers that share the profits of nostrum exploitation, no class receives greater financial benefit from "patent medicine" advertising than physicians. A hundred people see an advertisement of "Doan's Kidney Pills," with its "Every Picture Tells a Story" illustration conveying the impression that an ache or pain in the lumbar region indicates kidney disease. Out of this hundred, let us suppose one half, because of some passing pain in the lumbar region, are convinced that they have Bright's disease or some kidney ailment. Of the fifty thus frightened into the belief that they are ill, it may be conservatively claimed that considerably more than half will go to their family physician rather than to the drug counter. If all "patent medicine" advertising were abolished tomorrow, next to the exploiters of "patent medicine" and some newspaper proprietors, no one would suffer larger financial loss than the physician. The physician, of course, is opposed to the average "patent medicine" because it is exploited in such a way as to cause the public to magnify its trivial ailments, to drug itself unnecessarily and in cases in which something serious is the matter to lose vitally valuable time in seeking medical aid. Were the physician's attitude toward "patent medicines" prompted by commercial considerations he would say to the nostrum exploiter, "Go the limit; the more victims you get, the more patients I get!"

AN ECONOMIC EXCUSE FOR HOME REMEDIES

Under our present economic system there is a place for home remedies for the self-treatment of simple ailments. It may be that in Utopia the ailing always go to their medical advisers, no matter how trivial the ailment; but this is not Utopia. No one expects every person who suffers from a passing attack of constipation to go to his physician for a prescription. He is going to the drug store for a cathartic of some kind. Admitting that the abuse of cathartics is one of the most widespread and pernicious of the evils of self-drugging, and admitting, further, that the rational treatment of constipation may not call for any purgative drug, the fact remains that in such cases the man in the street is going to take cathartic drugs, at least until he is better informed. The duty of the medical profession in the premises is to warn the public of the danger of the purgative habit and to urge that some restrictions be thrown around the sale of cathartic medicines. The same applies to the use of other medicinal products that may rightly be classed as home remedies.

Unfortunately, the home remedies of today are, generally speaking, "patent medicines"; and the methods of promoting the sale of "patent medicines" make those products a menace to the public health. This not altogether for what the remedies themselves contain, although in many instances that is distinctly bad, but because of the way such products are exploited. Modern advertising differs from that of the mid-Victorian era in one vital respect. In the earlier days the advertiser notified the public where demands might be supplied. Today the advertiser bends his efforts toward making the public demand things which otherwise it would not want or even know about. This principle may have no serious consequences, other than economic at least, when applied to the ordinary commodities of commerce. There may be more or less plausible arguments in favor of so advertising pianos, automobiles, clothes, or what not, as to persuade the public to purchase more of these articles than it really needs or can afford. There can be no excuse, however, for using such methods in the sale of preparations for medicinal purposes. So to advertise as to make well men think they are sick and sick men think they are very sick, for the sole and only purpose of causing them to purchase drugs to pour down their throats, is more than an economic offense; it is a crime against the public health. Yet this is the principle on which the average "patent medicine" of today is sold.

SEQUENCE MISTAKEN FOR CAUSE AND EFFECT

There is an additional reason why the present method of exploiting drugs for the self-treatment of disease is vicious. In the sale of medicaments, we have a class of merchandise that lends itself peculiarly to fraudulent exploitation. The nonexpert who is led by misrepresentation to purchase a piano or a suit of clothes which is not up to the specifications learns sooner or later that he has been swindled, and he profits by the lesson. There is no such automatic check operating in the case of medicaments. John Smith gets up some morning feeling sick. It is but a passing indisposition and in a few days he will be himself again, whether he does something or does nothing in the way of treatment. In opening his morning paper, John finds, carefully detailed, just the symptoms that he seems to have, and he is assured that they may be cured by taking "Pink Pills," "Nuxated Iron," "Tanlac," "Peruna" or what not. On his way down town he buys one of these preparations. In a day or two he is well again—as he would have been in any case—and you never can persuade him that his recovery was due to the healing power of nature and not to the preparation that he had been taking. It is equally true, of course, that had he gone to his family physician and received a prescription or had gone to an osteopath and had his back rubbed, or called up a "Christian scientist" and received an absent treatment, he would also have been willing to credit any one of these agencies with his recovery. The point to be emphasized is that it is a very human tendency to credit to artificial agencies all results that are really due to natural causes. The *post hoc, ergo propter hoc* mode of reasoning is well-nigh universal, especially among those without scientific training. Even we of the medical profession are not altogether free from confusing a mere sequence of events with cause and effect. Here, then, is the reason for urging that in selling medicinal products a different method should be employed from that used in selling ordinary merchandise. The seller of general merchandise has nature as an opponent; wear and tear is constantly against him. The seller of medicaments always has nature as an assistant. The tendency of the human body in sickness is, in the majority of instances at least, to get well; but the healing power of nature seldom receives credit.

THE REMEDY

What, then, is the remedy? Obviously there should be home remedies available that are unobjectionable from the public health point of view. Such products should contain no habit-forming or dangerous drugs; they should not be recommended for diseases that are too serious for self-treatment; they should be nonsecret because the public has a right to know what it is taking; finally, they should not be advertised under false claims or in such a way as to make the public magnify trivial ailments and dose itself unnecessarily with drugs. Products which conform to these requirements are to be found on the shelves of every drug store in the country. They comprise certain simple official products from the United States Pharmacopeia or the National Formulary. Naturally, they are nonsecret, and being official, their standards of strength and purity are constant and enforced by state and national laws.

As most of the large pharmaceutical houses in the country make them, the element of monopoly is removed, and competition assures their being sold at a reasonable profit. The enormous overhead expense inseparable from the modern method of "patent medicine" exploitation is entirely eliminated. John Smith does not realize that when he pays a dollar for "Dr. Quack's Panacea," at least 75 cents of his dollar represents the cost of the effort on the part of Dr. Quack to convince Smith that there is something seriously wrong with him and that "Quack's Panacea" is the only thing that will cure him. In other words, Smith pays a dollar for 25 cents' worth of drugs and service, plus the privilege of being frightened into the belief that he is seriously sick and that these drugs are essential to his recovery.

Since official drugs, i. e., Pharmacopeial and National Formulary preparations, are nonproprietary, the chief incentive to fraudulent or misleading advertising claims is removed. John Doe & Sons' brand of Blaud's pills, differs in no essential respect from the Blaud's pills of Henry Rowe & Co. The margin of profit on the sale of Bland's pills is so small that it would hardly be profitable for one manufacturer to attempt any widespread advertising campaign for the special purpose of increasing the sale of his particular brand, even supposing it were possible for him to make claims that could not demonstrably be proved false.

When the public is properly informed, so that it knows what preparations to call for in order to treat its simpler ailments, advertising of home remedies will be entirely unnecessary. It devolves on the medical profession, and other agencies entrusted with the solution of public health problems, to give the public just these facts. In an article published two or three years ago,[1] Dr. Harvey W. Wiley suggested that the American Medical Association should appoint a representative committee to select a few simple home remedies for what he called the "Mother's Medicine Chest," which could be used by the public for the self-treatment of the milder ailments. He urged, further, that somewhat complete directions should be published, describing the nature of the troubles in which these remedies were to be used, and the amount that was to be given under various conditions, in every case, of course, calling attention to the potential dangers inseparable from self-diagnosis and self-treatment. Whether such a task should be undertaken by a scientific organization such as the American Medical Association, or by governmental agencies such as the United States Public Health Service, is a question. There is little doubt, however, that when such information has been widely disseminated, even if it takes a generation to do it, the making of hypochrondriacs by suggestion, and the widespread evil of unnecessary drugging, will be gone. Gone, too, will be the business of those nostrum exploiters who capitalize human fear and fatten on human credulity.

THE COST OF MALARIA

A STUDY OF ECONOMIC LOSS SUSTAINED BY THE ANDERSON-COTTONWOOD IRRIGATION DISTRICT, SHASTA COUNTY, CALIF.

HAROLD FARNSWORTH GRAY, Gr.P.H.
State District Health Officer, California State Board of Health
SACRAMENTO, CALIF.

I here present a summary of a detailed report that I made to the California State Board of Health, March 1, 1919, concerning the prevalence of malaria in the Anderson-Cottonwood Irrigation District, situated in Shasta County, Calif. The summary presents data as to the economic loss caused by malaria in this district in 1918. The three items of medicine, medical service and labor loss were carefully determined, and were found to average not less than $31.70 per family: in different sections of the district this varied from $1.86 to $75.10 per family per year.

DESCRIPTION OF THE DISTRICT

The Anderson-Cottonwood Irrigation District comprises approximately 32,000 acres of valley and foothill land lying on both sides of the Sacramento River in Shasta and Tehama counties, in the northern part of California. The population of the district is approximately 1,300 persons, of whom approximately 450 live in Anderson town, 200 in Cottonwood town, and the remainder, 650, on farms. The irrigation district was organized in 1914, and the irrigation system was sufficiently complete in 1918 to irrigate the northern half of the district (Anderson and Churn Creek sections) early in that year, and some water reached the southern part (Cottonwood section) late in that season. The water is obtained from the Sacramento River, at head-works located in the town of Redding, and is carried in an open, unlined earth main canal and laterals. The soil varies from loam to gravelly loam; the main canal is located very largely in a porous, open, gravelly loam, for much of its length on a sidehill. As a result, there is a very considerable seepage loss. This seepage from the main canal and laterals has greatly increased existing wet areas, and has caused many new seepage pools and marshes.

---

[1] Wiley, H. W.: The Mother's Medicine Chest, Good Housekeeping, October, 1916.

PRESENCE OF ANOPHELINE MOSQUITOES

Inspection has shown that these wet areas are ideal for the breeding of anopheline mosquitoes: in fact, *Anopheles* is the dominant species in this district. Very few places in which *culicines* breed were found. Observations made in previous years as well as in 1918 have shown that *Anopheles quadrimaculatus* is present, and probably *A. punctipennis*. I have not found *A. pseudopunctipennis*. Except in unusual years, mosquitoes did not prove troublesome to the inhabitants until the introduction of irrigation in 1918. Last year practically every one in the irrigated sections complained bitterly about the mosquitoes, and in many places their presence seems to have made life nearly unendurable.

PRESENCE OF MALARIA

Data in my possession seem to show that malaria was present in this part of Shasta County as far back as the early settlement in 1850. Three deaths from malaria were recorded in the county in 1873 (the first county record). There is a gap in the record until 1890, when deaths were again recorded; since 1906, the exact location of death has been entered on the record, and the deaths from malaria in this district were: in 1906, five; 1907, one; 1910, one; 1911, one; 1912, two; 1915, one; 1917, one; and 1918, six.

There is no record of the number of malaria cases in the district in past years. Although the regulations of the state board of health require that malaria be reported, this regulation is not enforced.

FINANCES OF THE DISTRICT

Realizing that the introduction of irrigation would mean a tremendous increase in malaria, already endemic in this district, I made studies in 1918 to determine the facts as basis for control recommendations. Because of the financial condition of the district, a special investigation into the economic loss caused by malaria was made.

The financial aspect of the matter may best be understood when it is known that the district, assessed at $1,538,180.47 in 1918, was bonded for $1,055,000 for the construction of the irrigation system. The irrigation district tax rate in 1918 was $7 on each $100 of assessed valuation, this tax being in addition to county and school taxes. To add an additional tax for malaria control, on top of this already heavy tax burden, would need evident justification if it were to be voted by the people.

METHOD OF INVESTIGATION

In making the investigation, practically every house in the district was visited, and data were obtained from approximately 80 per cent. of the families. Especial care was taken in every case to underestimate, rather than exceed, the probable cost of malaria to the family; large items were checked by corroborative evidence whenever possible. Owing to the conservatism of the investigation, it is practically certain that the costs obtained are less than the actual facts rather than in excess of them. Care was also taken in estimating the number of cases of malaria: many probable chronic cases which exhibited no definite symptoms in 1918 were not included. The investigation included only those items in the total cost of malaria (medicine, medical service and labor loss) which could be ascertained with some degree of certainty.

The item of medicine includes quinin, calomel, prescriptions and "patent medicines" purchased direct by the patients. The item of medical service includes physicians' fees, nurses' hire, hospital expense, and medicine dispensed directly by the attending physician. The item of labor loss includes only the labor loss of the head of the household or other wage-earning member of the family, charged at the prevailing local wage scale of $4 a day. It does not include casual farm labor, as this fluctuated greatly, and comparatively few farm casuals were in the district at the time of investigation (November, 1918, to January, 1919).

TABLE OF COSTS

In the table of costs herewith presented, the district is divided into six sections or groups; Anderson town, Anderson section (west side of the Sacramento River), Churn Creek section (east side of the Sacramento River), Ball's Ferry section (southeastern end of district), Cottonwood town, and Cottonwood section (southwestern end of district). The first three sections comprise the northern half of the district, and were under irrigation in 1918. The last three sections comprise the southern half of the district. Irrigation water reached a limited area in this part of the district late in the 1918 season.

SUMMARY OF MALARIA COSTS IN 1918, ANDERSON-COTTONWOOD IRRIGATION DISTRICT, SHASTA COUNTY, CALIF.

	Anderson Town	Anderson Section	Churn Creek Section	Ball's Ferry Section	Cottonwood Town	Cottonwood Section	Entire District
No. of families....	94	75	19	12	46	14	260
No. of persons.....	379	316	98	54	176	58	1,081
Persons having malaria symptoms in 1918.....	254	207	60	32	25	12	590
Percentage having malaria symptoms in 1918.....	67.0	66.5	61.0	59.0	14.0	20.0	54.5
Persons per family	4.03	4.21	5.16	4.5	3.8	4.14	4.16
Cost of medicines.	$504.25	$736.75	$117.00	$52.00	$56.50	$14.00	1,480.50
Per family.......	5.36	9.82	6.16	4.33	1.23	1.00	5.70
Cost of medical service.........	359.00	1,220.00	79.00	69.00	100.00	12.00	1,839.00
Per family.......	3.83	16.28	4.16	5.75	2.18	0.86	7.10
Labor loss*........	948.00	3,684.00	218.00	60.00	0	0	4,910.00
Per family.......	10.10	49.10	11.48	5.00	0	0	18.90
Cost of malaria in 1918 (for three items given above)........	1,811.25	5,640.75	414.00	181.00	156.50	26.00	8,229.50
Per family......	19.29	75.10	21.80	15.08	3.41	1.86	31.70
Per person......	4.79	17.80	4.23	3.35	0.89	0.45	7.66
Per person sick	7.64	27.20	6.90	5.66	6.27	2.17	14.05

* Labor loss is given for the wage-earning members of a family; casual labor is not included. The wage base is $4 a day.

An examination of the table discloses these salient facts:

1. Approximately half (54.5 per cent.) of the population of the district had malaria in 1918. The variation ranged from two out of every three persons (67 per cent.) in Anderson town and Anderson section, to one in every seven persons (14 per cent.) in Cottonwood town. The least malaria appeared where there was the least irrigation.

2. Labor loss, on the average, is the most important direct economic loss caused by malaria, with the cost of medical service second, and medicine third.

3. The cost of malaria due to the three items of medicine, medical service and labor loss averaged $31.70 per family, $14.05 per person sick, and $7.66 per person. In the most intensely malarial section of the district it averaged $75.10 per family, $27.20 per person sick, and $17.80 per person.

4. The total cost (three items) for the district in 1918 (assuming that $8,229.50 covered 80 per cent. of

the population of the district) was $10,400. Assuming that approximately the same incidence of malaria occurs in the southern part of the district in 1919, under full irrigation, as occurred in the northern part in 1918, the approximate loss for the entire district in 1919 will not be less than $13,500 for 325 families, or about $41.50 per family.

OTHER COSTS OF MALARIA

Other costs of malaria, for which no accurate data were readily obtainable, are:

1. Deaths from malaria. The six deaths in this district in 1918 probably averaged not less than $100 per funeral, in addition to the economic value of the lives lost.
2. The item of labor loss among casual laborers. This is known to be large, but could not be determined at the time of investigation.
3. Losses caused by inability to handle crops at the proper time, on account of malaria attacks. One known instance of this kind resulted in a definite loss of $120.
4. Losses on forced sales of property, by people leaving the district on account of malaria. Nine families made statements of intention to leave the district because of the malaria. In addition, the presence of malaria deters many families from buying land and developing it: three such cases came to my attention, and there were rumors of many more.
5. Losses due to vacant property, particularly in Anderson town, much of it due to the presence of malaria. At least twenty such vacant properties were observed, which have an annual rental probably not less, on the average, than $200.
6. Removal by many families from the district in the summer for the express purpose of avoiding the malaria if possible. Eight such cases came to my attention, and there are probably more. Such moves can hardly average a lower cost than $50 to the family: the economic loss to the community is probably much greater.
7. The loss due to depreciation of property values caused by the presence of malaria and mosquitoes. This cannot be definitely determined, but is probably greater than all other items combined. A conservative estimate would be between $5 and $10 per acre, or, say roughly, $250,000 for the entire district.

COST OF CONTROL MEASURES

The cost of drainage and mosquito control work in the district I have roughly estimated at $22,400 in the first year, $5,000 in the second year, and $3,800 in the third and subsequent years. Of the first year's expense, $12,000 is allowed for agricultural drainage and correction of interferences with natural drainage, which would be required regardless of the presence of malaria.

Estimating a 50 per cent. reduction of malaria in the first year, 75 per cent. in the second, 90 per cent. in the third, and 95 per cent. in the fourth year (our experience in California has shown that this is readily possible), four years' work should eliminate, in savings, the cost of malaria due to the three items of medicine, medical service, and labor loss, and should show a considerable profit in other items, particularly in appreciation of property values.

The organization of a mosquito abatement district, under the provisions of the state enabling act, has been advised as the first step in control measures.

THE SO-CALLED DOUBTFUL OR PARTIAL WASSERMANN REACTIONS

A PLEA FOR QUANTITATIVE RESULTS, AND DESCRIPTION OF THE WRITER'S METHOD

CHARLES E. SIMON, B.A., M.D.
Professor of Clinical Pathology at the University of Maryland School of Medicine and the College of Physicians and Surgeons
BALTIMORE

In the early days of the Wassermann work it was found that, while the majority of serums obtained from bona fide cases of syphilis gave complete complement fixation, when tested in the usual manner, only partial fixation was noted in a certain proportion, and notably in those that had been undergoing active treatment. The occurrence of such partial reactions, which were generally designated by the symbols ++, +, ± and even ∓, was interpreted as indicating the presence of relatively small quantities of the syphilitic antibody, and hence as a favorable symptom in those undergoing treatment, but nevertheless as indicating the existence of syphilis. Further studies then showed that such partial reactions do occur, as a matter of fact, in actual cases of the disease, but that every partial reaction does not necessarily denote syphilis. Generally speaking, the conclusion was reached that complement fixation, whether complete or incomplete, can only be regarded as indicating the existence of the disease in question provided the biologic reagents employed in the test are of standard quality and stand in a definite quantitative relation to each other; that the investigator does not use antigens in too concentrated a form, or complement in too small an amount (or what amounts to the same thing in an insufficiently active state), or the hemolytic amboceptor in insufficient or too large a quantity; etc.; for lack of watchfulness in any of these respects may give rise to partial reactions or, indeed, to complete reactions, though the patient is nonsyphilitic, or to negative results in individuals suffering from a bona fide attack of the disease.

Many investigators, realizing these possible sources of error, have attempted to eliminate them by various modifications of Wassermann's original technic, and it may be confidently asserted that many false diagnoses of syphilis could be avoided if the laboratory workers saw fit to adopt some of the suggestions that have been made. But unfortunately they have not done so, and as a consequence the clinician only too frequently finds himself in disagreement with the laboratory worker, and particularly so on the basis of the so-called doubtful reactions. Many laboratory workers still report such results by the symbol ++, etc., thereby suggesting to the physician not so much the doubt that he himself may feel, but the actual existence of the disease. As the general practitioner is not commonly versed in the intricacies of the Wassermann technic, the plus sign to him usually means that the patient has syphilis, and is hence a signal for active treatment, irrespective of the number of plus marks that may be reported, and many a poor victim no doubt has thereby been condemned to years of unnecessary treatment.

Just why so many workers still insist on exposing themselves to the pitfalls of the original or the early Wassermann technic it is difficult to say, as some of the sources of error, at any rate, are fairly well understood and might readily be avoided. In some instances an ultraconservatism is no doubt responsible for this reluctance to advance with the times—an ultraconservatism based on a general disinclination to deviate from the well-trodden path of the past. In other cases I have reason to assume that there is a tendency to leave well enough alone, on the ground that the original technic is time-consuming enough, as it is, and that any tendency to further lengthen the process would better be disregarded. Whatever the excuses may be, so much is certain, that no excuse is admissible when definite sources of error are disregarded at the expense of the patient.

In the present paper it is my purpose to discuss in some detail two factors that probably more commonly than any others are responsible for partial reactions and for negative reactions when syphilis actually exists.

THE COMPLICATING RÔLE OF ANTISHEEP AMBOCEPTORS IN HUMAN SERUMS

Various writers have called attention to the fact that human serums may contain antisheep amboceptors in variable but frequently sufficient amount to transform an otherwise positive into a partial or even a negative reaction. Noguchi has shown that one antibody unit is made negative by six amboceptor units, and three antibody units by ten amboceptor units when the Wassermann system, that is, the guinea-pig complement antisheep system, is used. Theoretically this is interesting enough in itself, as the observation raises the question whether the supposed union between complement, syphilitic antibody and antigen can be severed by an excess of amboceptor, if indeed this conception of the nature of the so-called complement fixation expresses what actually takes place. However this may be, the fact remains that syphilitic serums which do contain a sufficient quantity of antisheep amboceptor will show only a partial or, indeed, a negative reaction when examined according to Wassermann's original method.

As regards the frequency with which such amboceptors occur in human serums, the impression seems to be quite common among some Wassermann workers that they are, after all, rare and may properly be neglected in routine work. Why this should be the general view, it is difficult to understand, for it is a simple matter to convince oneself that the presence of these antisheep amboceptors, as they are usually called, is not only not rare but, on the contrary, exceedingly common. I would suggest that those workers who believe that their presence may be disregarded treat their specimens after the first incubation with the usual quantity of corpuscle emulsion and reincubate for five to ten minutes and then examine their tubes before adding the amboceptor. They will no doubt be surprised to find a number of negative and partial final reactions, even if all the serums were obtained from syphilitic patients, and they will be convinced thereafter that their work under such conditions can have no claim to accuracy or dependability.

I have not made any special note of the number of times that I have encountered normal antisheep amboceptors in human serums in sufficient quantity to make a truly positive serum give either a partial or a negative reaction, but I have seen it so often as to have convinced myself quite early in my Wassermann work that this source of error must be eliminated. Noguchi reports that of 326 serums that he examined only twenty-three contained no antisheep amboceptors at all; that in 192 the quantity amounted to two units or more and in ninety-eight to four units or more—figures that speak for themselves.

Of the desirability of avoiding this source of error there can be no question. The problem is merely whether this can be done. Two methods have been proposed to this end.

Noguchi suggested the substitution of an antihuman system for Wassermann's antisheep system, and in certain laboratories this method of procedure is followed, and no doubt obviates, in most cases, errors arising from this source. I have myself advocated the removal of the natural amboceptors by extracting with sheep corpuscles, and those workers who have been sufficiently interested in this method to run parallel examinations, with and without extraction, are no doubt fully convinced of the necessity of the step and of the facility with which this can be done.[1]

Either method will prevent the obscuring of a positive reaction by the substitution of a negative or a partial reaction, provided a sufficient quantity of the syphilitic antibody is present. Neither method, however, in itself, takes this latter factor into consideration, whereas this factor is at least as important as the presence of natural amboceptors. We shall consider this in detail in the following section.

VARIATIONS IN THE QUANTITY OF THE SYPHILITIC ANTIBODY IN THEIR RELATION TO PARTIAL REACTIONS

Recent investigations have shown me that in the presence of large quantities of the syphilitic antibody—in the standard dilution of 1 : 5—complement fixation takes place instantaneously, without any incubation whatsoever, especially if the total bulk of the diluted serum, antigen and complement is small, so that immediate contact of the various ingredients with each other is assured. If, for example, the standard volume for each component, in appropriate dilution, is 0.2 c.c., the hemolytic amboceptor and corpuscles may be added immediately following a simple shaking of the tube containing the patient's serum, the antigen and the complement, and it will be noted that on incubating an absolutely sharply cut triple or quadruple plus reaction, without any trace of hemolysis, may be frequently obtained. Evidently the velocity of the reaction under such conditions is enormous.

If now such a serum is further diluted, it will be observed that an instantaneous reaction can no longer be obtained, but that under the conditions of the experiment just described hemolysis of variable degree, i. e., a partial reaction, will occur. On incubation for a variable length of time before the addition of amboceptor and corpuscles, it will be noted, however, that complete fixation of the standard quantity of complement may be obtained, nevertheless. The length of time that is required to secure complete fixation depends on the degree of dilution; in other words, on the quantity of the reacting substance. The smaller this is, the more prolonged will the incubation period have to be. This may be expressed by stating that the velocity of the reaction is proportionate to the quantity of the reacting substance, or that the period of time necessary for complete fixation varies in inverse proportion to the quantity of the reacting substance.

---

[1] The majority of workers who do not use Noguchi's antihuman system fail to do so because of the difficulty of obtaining a high titer antihuman amboceptor.

A couple of examples will illustrate this:

1. A serum obtained from an active syphilitic in the second stage gave an instantaneous reaction in the usual dilution of 1:5. Dilutions were then prepared in the proportion of 1:10, 1:20, 1:30, and sets of 0.2 c.c. each were now combined with an equal quantity of antigen and complement, and incubated for varying lengths of time, amboceptor and corpuscles being finally added to test the extent of the complement fixation. The results are shown in Table 1.

TABLE 1.—REACTIONS OF VARIOUS DILUTIONS OF SERUM AFTER VARIOUS TIME PERIODS FROM AN ACTIVE SYPHILITIC IN THE SECOND STAGE

	Immediate Reaction	Reaction after Incubation for				
		10 Min.	20 Min.	30 Min.	40 Min.	50 Min.
Dilution 1:5........	+++	+++	+++	+++	+++	+++
Dilution 1:10.......	+++	+++	+++	+++	+++	+++
Dilution 1:20.......	0	0	0	++	++	+++
Dilution 1:30.......	0	0	0	0	0	0

2. In Table 2 will be found the reactions of serum obtained from a quiescent syphilitic in the third stage.

Such findings unquestionably warrant the conclusion that unless a patient's serum contains a certain quantity of the so-called syphilitic antibody complete complement fixation will not be obtainable within the usual incubation period of thirty minutes, which seems to have become the standard in the various laboratories the country over, but that a partial reaction will result if the amount is sufficient to that end, or a negative reaction if the quantity be particularly small. It would further follow that the meaning of such doubtful reactions could be determined by repeating the test with a longer period of incubation, and that in certain cases the presence of syphilitic antibody could still be definitely established by such means, whereas routine examinations along the old lines would lead to a negative result.

TABLE 2.—REACTIONS OF VARIOUS DILUTIONS OF SERUM OBTAINED FROM A QUIESCENT SYPHILITIC IN THE THIRD STAGE

	Immediate Reaction	Reaction after Incubation for				
		10 Min.	20 Min.	30 Min.	40 Min.	50 Min.
Dilution 1:5........	+	+++	+++	+++	+++	+++
Dilution 1:10.......	0	++	+++	+++	+++	+++
Dilution 1:20.......	0	0	+	+	++	+++
Dilution 1:30.......	0	0	0	0	0	0

TABLE 3.—RESULTS OF LONG INCUBATION IN SERUMS CONTAINING ONLY A SLIGHT QUANTITY OF THE SYPHILITIC BODY

Case	Stage of Disease	Reaction after Incubation	
		For 30 Min.	For 60 Min.
B.	Tertiary stage	Partial	Complete
McC.	Tertiary stage	Negative	Complete
W. W.	Tertiary stage	Partial	Complete
H.	Primary (3d day)	Partial	Complete
1616.	Secondary	Partial	Complete
P. M.	Early tabes	Partial	Complete
I. S.	Tertiary	Partial	Complete

A few examples illustrating this point have been collected and are shown in Table 3, the first column indicating the result at the end of thirty minutes' incubation, the second after an hour's incubation.

SUGGESTION FOR A NEW SYSTEM OF DENOTING RESULTS

As the period of incubation that is necessary to effect complete complement fixation is thus unquestionably an index of the quantity of the reacting substance, it has occurred to me that on this basis a numerical scale for denoting partial reactions could be established that would prove more satisfactory and would yield more information than our old system of marking by plus signs, from which all of us would no doubt be only too glad to be released. In many laboratories the confusing ++, +, ± and ∓ signs are no longer used, and I sincerely believe it would be a wise step to eliminate these, and the three and four plus signs as well, and to substitute definite figures.

TABLE 4.—PROPOSED SYSTEM OF DENOTING REACTIONS

1 unit	requiring	60 Min.	for fixation,	would represent	1.0 per cent.
10 units	requiring	50 Min.	for fixation,	would represent	16.6 per cent.
15 units	requiring	45 Min.	for fixation,	would represent	25.0 per cent.
20 units	requiring	40 Min.	for fixation,	would represent	33.3 per cent.
30 units	requiring	30 Min.	for fixation,'	would represent	50.0 per cent.
40 units	requiring	20 Min.	for fixation,	would represent	66.6 per cent.
45 units	requiring	15 Min.	for fixation,	would represent	75.0 per cent.
50 units	requiring	10 Min.	for fixation,	would represent	83.3 per cent.
60 units	requiring	0 Min.	for fixation,	would represent	100 or more

I should therefore propose to designate as a unit such quantity of the syphilitic antibody as requires sixty minutes' incubation at from 37 to 40 C. to bring about complete fixation of a standard amount of complement. Such amount of the syphilitic antibody as is capable of fixing the same quantity of complement without any incubation whatsoever I should designate as sixty units and a reaction of the latter type I should term a 100 per cent. reaction. I have chosen the above quantity as the standard unit for the reason that when one progressively dilutes a serum that in the usual dilution of 1:5 will give an instantaneous reaction complete fixation in the highest dilution will require an incubation of sixty minutes.

According to this plan, then, the various percentages would correspond to definite units of the reacting substance on the basis of the number of minutes necessary to secure complete fixation of a standard amount of complement in the presence of a standard quantity of antigen, as illustrated in Table 4.

TABLE 5.—LENGTH OF TIME NECESSARY TO SECURE A +++ REACTION, TOGETHER WITH THE CORRESPONDING VARYING QUANTITIES OF ANTIBODY

Case	Time Necessary to Bring About Complete Fixation, i. e. a +++ Reaction	Corresponding Content of Antibody
J. S.	45 minutes	25.0 per cent.
P. M.	30 minutes	50.0 per cent.
1616.	60 minutes	1.0 per cent.
Mrs. D.	10 minutes	83.0 per cent.
Mrs. W.	30 minutes	50.0 per cent.
L.	5 minutes	91.6 per cent.
Y.	1 minute	100.0 per cent.

Such a system of denotation would, in my opinion, be more logical than our plus signs. Every percentage figure would indicate that syphilitic antibody is actually present and would give an idea of the relative amount. With our present system, all of our +++ cases by no means contain the same quantity of reacting substance, as is clear from the varying length of time that is necessary to secure a +++ reaction.

This is well shown in Table 5, all the cases of which gave complete fixation, the time necessary to bring this about, varying, however, as indicated.

While the method suggested will, it is thought, be helpful in the study of +++ cases as designated by the old system, it is proposed chiefly for the purpose of eliminating doubtful or partial reactions, which in the past have been so troublesome and confusing both to the laboratory worker and to the physician.

PROBABLE MECHANISM UNDERLYING THE PRODUCTION OF PARTIAL REACTIONS

Let us consider the probable mechanism underlying the production of partial reactions due to the presence of small quantities of syphilitic antibody. In the past our conception of the nature of the Wassermann reaction has been that the syphilitic antibody and antigen combine and that complement is taken up by the resultant product. The dependence of the degree of complement fixation on the element of time, noted in the present paper, suggests that this idea must be somewhat modified. Evidently the reaction follows the law of mass action, the antibody itself apparently playing the rôle of a catalytic agent, which we may conceive as entering into some sort of a combination with either the complement or the antigen, but from which it is at once released when its temporary mission has been accomplished. If this is true, we can readily understand that in the presence of a large number of antibody units, each unit entering into action at the same time, complement fixation would occur with such rapidity that incubation is not necessary at all, the reaction being completed before the hemolytic amboceptor and corpuscles can be added, no matter with what haste this may be done. Similarly, of course, a variable length of time would be necessary to bring about the same result if the quantity of the reacting substance is less, and it will readily be understood that when this falls to a certain level only a fraction of the complement will have been fixed by the time the old standard incubation period of thirty minutes has been reached, and the remainder coming in contact with the hemolytic amboceptor and corpuscles at this time will now bring about partial hemolysis and hence lead to an inconclusive result. A prolongation of the incubation period, on the other hand, would lead to an increasing degree of fixation and under suitable conditions to a complete reaction, provided, of course, the factor that is responsible for the incomplete reaction under the old conditions of the experiment is in reality the one that we have just been considering. If this factor is not operative, and if the presence of natural hemolysins has been excluded, it may be confidently asserted that partial reactions cannot be referred to the existence of a syphilitic infection, and in such case it will be noted that the degree of fixation does not increase with the lengthening of the period of incubaion.

PROPOSED TECHNIC

In discussing my work with some of my colleagues it was suggested that, since the Wassermann technic, even with the present system, is so time-consuming, every effort should be made to simplify it and not to lengthen the process by the introduction of any additional steps. I fully realize such a desideratum and would favor any change that would cut down the necessary time, provided this could be done without detracting from the accuracy of the test. But accuracy must, after all, be our prime consideration. However, I believe that I have succeeded in reducing the time required for routine examinations to such an extent by certain changes in technic that, even with the additional manipulations proposed for the purpose of obtaining quantitative results, and of eliminating doubtful reactions, the method as given in greater detail below will prove more expeditious than the technic now in vogue.

Before going on to a description of the method that I should advocate for general adoption I would like to discuss in detail a few technical questions that have not received the attention of laboratory workers that they deserve.

TIME REQUIRED FOR THE EXTRACTION OF NATURAL AMBOCEPTORS

The majority of workers who prefer to extract the natural amboceptors by means of sheep corpuscles do so by diluting a given volume of the serum with four or five volumes of the standard corpuscle emulsion, and incubating for thirty minutes at from 37 to 40 C., after which the corpuscles are thrown down by centrifugation and the supernatant fluid is further treated in the usual manner.

The question arises as to how many units of natural antisheep amboceptor may be present in a human serum and how large a quantity of sheep cells are necessary to remove such an amount in a given length of time. That thirty minutes are more than sufficient I have shown long ago. Recent studies, however, have convinced me that a ten minute incubation period will suffice to extract from 0.4 c.c. of serum at least eighty units of amboceptor that has been artificially added, and that fifty units may indeed be removed in five minutes by four volumes of a 2.5 per cent. emulsion of sheep corpuscles (having reference to a 2.5 per cent. emulsion prepared from corpuscle mush). As Noguchi has shown that the content of human serums in antisheep amboceptors rarely exceeds ten units in 0.2 c.c. of serum, it is clear that a longer incubation than ten minutes is unnecessary and that a ten minute period may well serve as standard for extracting 0.4 c.c. of serum with 1.6 c.c. of standard sheep corpuscle emulsion.

TIME REQUIRED FOR THE INACTIVATION OF SERUMS

In the past it has been customary to inactivate serums by exposure to a temperature of 56 C. in a water-bath for a period of thirty minutes. For larger volumes this may be necessary, but for such quantities as we commonly use in Wassermann work a shorter period will bring about the desired result, and for 0.4 c.c. portions inactivation for ten minutes is all that is necessary, as is seen from the following protocol:

TABLE 6.—EFFECT OF EXPOSURE TO 56 C. FOR VARYING LENGTHS OF TIME ON COMPLEMENT CONTENT OF SERUM

Length of Exposure	Evidence of Hemolysis
5 minutes	Faint trace
10 minutes	None
15 minutes	None
20 minutes	None
25 minutes	None
30 minutes	None

Four tenths c.c. portions of human serum were exposed to a temperature of 56 C. in the water-bath, for varying periods of time, as indicated in Table 6, and then diluted with four volumes of saline. Of the resultant dilutions 0.5 c.c. portions were treated with two and a half titer doses of antisheep amboceptor and a corresponding volume of corpuscle emulsion. The tubes were then incubated for fifteen minutes at from 37 to 40 C., centrifugalized and the supernatant fluid examined for evidence of hemolysis.

AMOUNT OF COMPLEMENT TO BE USED AND TIME TO BE ALLOWED FOR FIXATION

With the original Wassermann technic it was customary to allow sixty minutes for the fixation of the complement, in the ordinary warm air incubator. Subsequently, when the water-bath incubator came into use, owing to the possibility of maintaining a more constant temperature and of bringing the contents of the tubes more quickly to the desired warmth, the time was cut down to thirty minutes. As I have shown above, however, the period of incubation necessary to secure complete complement fixation varies with the quantity of the syphilitic antibody, the amount of complement and antigen remaining the same. The larger the amount of complement, the amount of the antigen and the antibody remaining the same, the longer will have to be the period of incubation. This is shown in Table 7.

TABLE 7.—LENGTH OF TIME NECESSARY TO FIX VARYING AMOUNTS OF COMPLEMENT, THE QUANTITY OF ANTIBODY AND ANTIGEN REMAINING CONSTANT

Degree of Complement Fixation in	Number of Complement Units									
	1	2	3	4	5	6	7	8	9	10
60 minutes	+++	+++	+++	+++	∓	0	0	0	0	0
90 minutes	+++	+++	+++	+++	+++	+++	∓	0	0	0

From these observations the conclusion would suggest itself that satisfactory end-results could be obtained most rapidly if small quantities of complement were used and relatively large amounts of the patient's serum. In my own work, however, I have adhered to 0.2 c.c. of a 1:10 dilution of complement in combination with 0.2 c.c. of a 1:5 dilution of the patient's serum, and a standard incubation time of ten minutes, unless special reasons existed for suspecting the presence of especially small quantities of syphilitic antibody. The antigen, of course, was used in like amount. With these volumes complete complement fixation will be obtained not only in ten minutes in the vast majority of syphilitic serums, but even without any incubation in most of the untreated cases.

METHOD OF THE WRITER

The patients' serums are collected in the usual manner and separated from the corpuscles by centrifugation. Four tenths c.c. are inactivated for ten minutes at 56 C., intimately mixed with 1.6 c.c. of a 2.5 per cent. corpuscle emulsion (the percentage figure has reference to corpuscle mush and corresponds to 5 per cent. when the mush is first diluted to the original volume of the defibrinated blood that was placed in the centrifuge tubes) and extracted for ten minutes by incubating at from 37 to 40 C. in the water-bath. The corpuscles are then thrown down and the tubes are charged with 0.2 c.c. portions of the clear supernatant fluid, to which 0.2 c.c. portions of the antigen dilutions, the complement dilution, and in the case of the control tube, of saline instead of antigen are added. After they are shaken, the mixtures are incubated at from 37 to 40 C., in the water-bath and then tested for the presence of free complement by the addition of 0.2 c.c. of amboceptor (two and a half titer doses) and 0.2 c.c. of corpuscle emulsion (of the same strength as the one employed for purposes of extraction), the tubes being returned to the water-bath and left for ten minutes, or at least until the control tubes are completely hemolyzed. The negative cases can then be read off at once and reported as such.

Those tubes in which complete hemolysis has not occurred are centrifugalized and the color of the supernatant fluid is noted. If this is colorless the examination may be reported as positive without further comment, or another set of tubes may be charged with the same reagents and in the same sequence, and thoroughly shaken after the addition of each, but not incubated at all before the addition of the amboceptor and the corpuscles. If the specimen is then incubated until the control tube is hemolyzed, and complete complement fixation has occurred, as manifested by lack of any hemolysis on final centrifugation, we are dealing with a 100 per cent. reaction. If partial hemolysis has occurred another set of tubes may be prepared and incubated for five minutes after adding the complement, and before testing for its fixation. If complete fixation now occurs we note the result as 91.6 per cent., while partial hemolysis in this set also, but complete fixation in the ten minute specimen, would place this in the 83 per cent. group.

Those specimens that gave a partial reaction on first examination, after ten minutes' incubation, are now further examined, to which end I usually put up a double set, of which the one is incubated for thirty minutes and the second for sixty minutes before adding the amboceptor and the corpuscles. If this is done, and all reagents have been functioning properly, it will be noted that every doubtful reaction will now resolve itself either into a straight negative or a straight positive reaction, the cause of the partial reaction at the end of the primary incubation for ten minutes being due, in syphilitic cases, to the presence of smaller quantities of the reacting substance which, as has been previously shown in this paper, require a longer period of time to perform the work prescribed.

As we have taken as a unit that quantity of syphilitic antibody contained in 0.04 c.c. of concentrated serum, which is equal to 0.2 c.c. of the diluted and extracted original 0.4 c.c. with which we started and which requires sixty minutes' incubation in the water-bath to completely fix 0.2 c.c. of our complement dilution in the presence of 0.2 c.c. of our standard antigen dilution, we denote such a reaction as a 1 per cent. reaction, whereas one occurring instantaneously; that is, without incubation, indicates a 100 per cent. reaction. The intervening values may be graded accordingly as already explained.

Partial reactions due to accidental factors, errors of technic, improper reagents, etc., never resolve themselves in the manner just described. They either disappear, or remain constant irrespective of the time of incubation; there is never a consistent increase in the degree of complement fixation as the period of incubation is lengthened, such as small amounts of syphilitic antibody will evoke.

Using the technic as outlined above, any worker who is sufficiently interested will, I am sure, not be disappointed in the results. To cite large series of cases illustrating its accuracy seems without purpose, particularly in view of the fact that many of the procedures with which the findings might be controlled are so thoroughly faulty that they would not constitite a proper control. I can warmly recommend the method, if for no other reason than the fact that it disposes of the troublesome problem of the doubtful or partial reactions.

had wasted precious years. He had brains and he worked. He simply was not given what he longed to have.

Many of these men, both young and mature, I have come to know with an intimacy that only army camp life can afford; they have been my loyal assistants, and I feel a deep personal affection for them; and I know what I say when I assert that those who were not competent were not so by choice. They retained potential growth, and they grew when they were taught and helped. Sixty-six per cent. of the graduates last year took their degree in what we call Grade A schools. Evidently the time is ripe for a regrading.

My personal experience in base hospitals can be briefly summarized. Physicians, irrespective of age, who had served at some time as interns in good hospitals were usually efficient, safe, and trustworthy. These men, as a rule, were graduates of good medical schools, but this was not invariably the case. There were notable exceptional cases in which men had graduated from mediocre schools and had appointments as interns in good hospitals. In the second place, men who had not had some hospital experience, or who had been interns in poor hospitals, were usually inefficient, ignorant of common methods of diagnosis, and were not to be trusted with the seriously sick. Some of these men came from good schools and their scientific point of view was, perhaps, correct; the majority, from weaker schools, had no point of view at all. In the practical workings of a large hospital staff intrusted with the care of from 500 to 1,000 patients, there was no exaggerated refinement in determining a physician's qualifications to care for the sick.

What I have detailed as my personal experience would, I believe, be concurred in generally by chiefs of military hospitals. I have discussed the subject in all its details with a good many of them. Many of us have been teachers of clinical medicine all our lives and were vitally interested. Nearly a year ago I wrote down my impressions of the general practitioner who had not had good hospital training, as I have seen him in camp and hospital; and I submitted this impression to three other chiefs who were, like myself, teachers. Not one said it was an exaggeration. These impressions were as follows:

1. The practitioner of this class cannot differentiate a systolic from a diastolic murmur; in consequence, he is wholly incompetent to express an opinion about a cardiac disorder.

2. He cannot differentiate pleural effusion from pneumonia. He has never done a thoracentesis, so he cannot correct his own tendency to error.

3. He cannot recognize meningitis and has never done (often never seen done) a lumbar puncture, hence he cannot treat the disease.

Occasionally he has never seen diphtheria, though he has seen "membranous croup" which terminated fatally. A few had never seen diphtheria antitoxin administered.

The diseases I took for my basis are the common diseases. Pneumonia for years has been the "master of the men of death." We are all alike helpless enough, but what is the value of the physician if he cannot recognize complications which have a remedy when recognized? Of what help is a meningitis serum, if the disease is not diagnosed? The keystone of medicine is diagnosis; without it the structure collapses.

RECOGNITION OF DEFECTS IN MEDICAL EDUCATION NECESSARY

A frank and honest recognition of the defects in present medical education is necessary for any progress toward betterment. This discussion will result in no good unless it leads to reorganization of medical schools and in teaching hospitals. In the last decade, the emphasis has been placed on the laboratory aspect of medicine. Probably that was correct, because a scientific point of view was at that time generally lacking. But we must not make the mistake of believing that the scientific care of the sick can be taught in the laboratory. It can be taught only in one place, a hospital ward. It can be taught only in one way, by a competent clinician at the bedside to a small group of students. Medical schools that do not command large hospital facilities with adequate funds to utilize all scientific methods in the diagnosis and treatment of disease, and adequate funds for a large teaching staff, cannot teach clinical medicine.

There are quite a number of medical schools classed as Grade A which have not these opportunities to offer to their students, and on that account they are heavily handicapped in training students for the practice of medicine in any of its branches. The science of medicine can be taught in the laboratory and didactically; the art of medicine cannot be so taught. What I mean is this: A good pathologist ignorant of the art of medicine can make a diagnosis if one bring him certain facts relative to the physical signs in the case. But the same pathologist could probably not elicit those signs at the bedside. It is the ability to examine a patient and to gather the important data which constitutes the art of diagnosis. This art cannot be taught didactically; it may be taught successfully only at the bedside. All of my observations have gone to confirm me in the belief that the general practitioner is inefficient because he does not know how to examine patients. At the School of Military Medicine, Fort Oglethorpe, two weeks of the brief course was expended in teaching this fundamental art. Brief and superficial as the course had to be, many a physician who had graduated within the last decade from a school reputed to be good asserted that this superficial course gave him more than his school had given.

Clinical instruction has improved markedly in the last decade in recognizing the requirements for teaching diagnosis, but there is not yet anything like a general adoption on the part of medical schools of bedside teaching or the clinical clerk system. Except in a relatively small number of very high grade schools, these modes of instruction are farcical. There seems little doubt in the mind of any one as to the desirability of this method; the difficulty has been to secure hospital facilities for medical schools and to afford financial outlay for the salaries of the corps of instructors. The program for the future in medical schools must take into account these features, in the same way that in the past attention has been paid to the laboratories of the fundamental sciences. At best, medical schools can teach only principles and methods. The bright graduate of the best of schools is wholly unfitted to practice medicine. He knows principles and he knows methods; he knows types of diseases, perhaps. He does not know variations in types and he is lacking in the experience which renders him safe. From the point of view of public welfare, the required hospital year cannot come too soon. However, the mistake must not be made in this country which has been made in some countries, that a year in any hospital is acceptable. This formative period spent under the direction of a poor clinician has only bad habits and erroneous ideas for its result. Some way must be found whereby medical schools or the state can designate the hospitals in which men may serve their internship.

NECESSITY FOR IMPROVED CLINICAL INSTRUCTION

Reluctantly I have been forced to the conclusion that training in a first class hospital is equally as important, if not more important, than undergraduate instruction in fitting physicians to care for the sick. So many examples have come to my notice of men who had graduated from schools known to be mediocre or worse, but who had a hospital service under an excellent attending physician who had left the mark of his teaching and influence on his assistants. But better far no internship at all than the blighting and pernicious atmosphere that young men come into in many poor hospitals. The welfare of the public is our concern—the reason for our profession. We would better lead where soon we needs must follow. Signs are not wanting that more is demanded than is now given. A test of fitness to practice could be met only by men trained in good hospitals, for the test will be the ability to recognize, to diagnose, disease—a practical test.

My ideas of the defects in medical education, as revealed by the product of the medical schools, would indicate that progress for the future in teaching the clinical subjects must be along lines of practical, intimate instruction in the art and science of diagnosis. We must teach students how to examine patients with that same minuteness and thoroughness of analytical method that is used in the bacteriological laboratory in the differentiation of bacterial types. The laboratory of clinical medicine is the ward. Nothing can take its place. Didactic teaching, the lecture, and the clinic should be relegated to an entirely subordinate position. They have a use, but a subordinate use.

A thorough revision of the list of Grade A schools should be made from the point of view of their ability to meet the demands of practical instruction, in the clinical years. Schools that cannot hope to have in the future the funds and the hospital facilities necessary for teaching medicine in the final years should offer only the fundamental sciences.

This point of view may seem novel in coming from one who has spent much of his time in laboratories, in research, and who has done what he could to promote the spirit of investigation among students. I am not losing sight of the need of that group of students, but numerically that group will always be small. The promising investigator is the exception, and he can be handled in the exceptional way. The average student in medicine, as the average student in law or theology or chemistry, has no mind for abstractions; he has scant ambition to be a scientist. His tastes and his inclinations are quite otherwise, and we must not forget that modest intellectual ambition does not unfit him for great usefulness, if he is given proper training.

Is Your Community Fit?—Have you any definite information as to the prevalence of preventable diseases in your city? Without such information health officials cannot direct their activities in a way that will yield the largest returns in disease prevention. All doctors must report such diseases as part of their responsibility to the community.—*Pub. Health Rep.*, April 25, 1919.

THE PRODUCTION OF INDOL BY CERTAIN STRAINS OF THE PFEIFFER BACILLUS *

EDWIN O. JORDAN

CHICAGO

So few positive cultural characters have been recorded for the Pfeiffer bacillus that each additional biologic quality is of some interest. I have not found any statement that a previous test for indol production has been made. Zipfel,[1] who seems to have carried out the most comprehensive series of observations by modern methods on the production of indol by bacteria, lists only four groups as indol-formers (*B. coli* group, *B. dysenteriae* Vars. Flexner and Y, the cholera vibrios and the cholera-like vibrios excepting V. Finkler-Prior and V. Deneke) and sixteen groups as not forming indol. Pfeiffer's bacillus was apparently not among those tested.

The majority of strains of the Pfeiffer bacillus that I have been able to obtain form indol promptly. The paradimethylamidobenzaldehyde method is used. A satisfactory medium is standard meat infusion broth to which 5 per cent. of sheep blood is added while the broth is hot (above 90 C.) and which is then filtered through cotton or filter paper.

In all, thirteen strains of the Pfeiffer bacillus have been tested. These include two strains from fatal cases of influenza—one from heart blood, the other from lung tissue. Seven strains are from normal throats and one from influenza sputum; the source of the others is not known. All show the hitherto recognized cultural and morphologic characters of the Pfeiffer bacillus. Ten of the thirteen strains produce indol abundantly in twenty-four hours. Two of the three strains giving negative results are from normal throats; the source of the other is not known. Five strains are from Chicago, four from Rochester, Minn., two from Washington, D. C., and two from New York City. The three strains not producing indol are from Chicago, Washington and Rochester, respectively.

It seems possible that this character may be usable for a rough preliminary differentiation of the indol-producing Pfeiffer bacilli or for a "presumptive test" of their presence. The other bacteria commonly found in the throat do not appear to be indol-formers. Zipfel and others have reported finding no evidence of indol production by the various cocci and I have tested thirty-six different strains of green-producing and hemolytic streptococci, pneumococci, meningococci and staphylococci from the mouth, with uniformly negative results. Diphtheria bacilli were reported by some of the earlier workers as forming indol, but later investigators have generally not confirmed this. Zipfel tested twenty-seven strains with a negative outcome. I have obtained no indol products with any one of five strains.

Simultaneous inoculations of blood broth with pure cultures of the Pfeiffer bacillus and of the ordinary mouth cocci have shown that the Pfeiffer bacillus is able to grow in competition with the other organisms, and that the mixture, like the pure culture, yields a good indol reaction in twenty-four hours.

It was thought that throat swabs washed directly into the broth might give an indication of the presence of indol-producing Pfeiffer bacilli. Fifty-eight different normal persons have been examined with this in view. A positive indol reaction has been obtained in forty-eight, a negative in ten, making the proportion of positive indol findings from throat swabs about 83 per cent. Seven of the persons giving positive indol reactions from throat swabs had a history of influenza in the fall of 1918; also three of those giving negative reactions.

---

* Influenza Investigations, U. S. Public Health Service.

[1] Zipfel: Centralbl. f. Bakteriol. I, Orig., 67: 572, 1913.

Seven of those giving negative indol reactions were retested (from a few days to a few weeks later) and four of these yielded indol on the second testing. In three of these both tonsil and nasopharynx swabs gave indol; in the other only the tonsil swab.

If a peptone phosphate medium is used in which *B. coli* and other indol-producing bacteria give abundant indol, no indol is formed after inoculating with throat swabs although good growth occurs. Parallel tests with swabs taken from the same throat at the same time have shown indol production in the blood broth but never in the peptone phosphate medium. Apparently, therefore, a hemophilic organism is the one responsible for the indol production from throat swabs.

It seems a fair presumption from the available data that indol production in blood broth inoculated with throat swabs is due to the presence of indol-producing strains of the Pfeiffer bacillus, although a final judgment on this point is hardly possible at the present time. Should this presumption prove to be justified, these results indicate the presence of Pfeiffer bacilli of this type in approximately 80 per cent. of normal throats. This is a higher proportion than usually obtained by the ordinary cultural methods. In the cases examined in this series the presence of the Pfeiffer bacillus was indicated in about 40 per cent. by the blood agar plate cultural method, as compared with about 80 per cent. by the indol presumptive test.

Clinical Notes, Suggestions, and New Instruments

A METHOD OF DELIVERING THE PLACENTA

JOSEPH L. BAER, M.D., CHICAGO
Associate Attending Obstetrician and Gynecologist, Michael Reese Hospital

I desire to present a procedure for the expulsion of the placenta. Physicians in general have accepted the dictum that the third stage of labor should be allowed to develop naturally, and that no attempt should be made to express the placenta until separation has occurred, provided there is no hemorrhage.

The interval between the birth of the child and the moment of expression of the placenta is still being handled in different fashion, according to the teachings of various clinics, ranging from the absolutely let alone policy of Leopold, who insists that the abdomen should be left untouched following the birth of the child, if need be for twenty-four hours, leaving the expression of the placenta absolutely to the natural powers of the woman;. to the other extreme, which consists in grasping the fundus, and as soon as contractions have appeared or have been called forth by massage, to express the placenta. Omitting a critical consideration of the merits of these various procedures at this time, and limiting myself to a discussion of the act of expulsion, I think the consensus of the best obstetrical opinion of today, in this country at least, is that after a suitable period of waiting, which averages half an hour, the uterus having undergone sufficient contractions, the placenta being separated and lying in the lower uterine segment, it is then permissible to grasp the fundus directly over its center, and the uterus being in contraction and in midline, to express the placenta.

In skilled hands, with a proper recognition of the risk of too much traumatism resulting in a metritis, and of rupture of a pus tube by grasping the fundus laterally instead of centrally, this procedure is entirely without danger. However, if there is a way in which the natural powers of the woman, both voluntary and involuntary, can be utilized for the purpose of expression without handling the uterus, I am sure this is preferable. All of us have seen the not infrequent cases in which the woman spontaneously expels the placenta directly after delivery, or just as we are about to express it for her. In a great majority of cases her inability to accomplish expulsion spontaneously is due to the complete loss of tone of the abdominal wall just released from its prolonged condition of overstretching. If the abdominal tone and the intra-abdominal pressure can be restored for the time being, the woman has regained her voluntary powers of expulsion.

For some time I have been accomplishing this in a very simple way. After the usual period of waiting, averaging half an hour, and when the uterus is at the height of a contraction, as evidenced both by feeling it and by the pain the woman is experiencing, I grasp the abdominal wall crosswise above the fundus and pull the rectus muscles together, thus taking up all the slack. I then encourage the woman to bear down, and in practically every case in which expression on the fundus would have succeeded, this procedure has succeeded. If then there should be adherent membranes, they are treated in exactly the same fashion as following any other method of expression. The advantage claimed for this procedure is a total avoidance of handling or pressure on the uterus, and I believe that any device that will help to achieve that end, and give the same result, is worth advocating.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION. W. A. PUCKNER, SECRETARY.

PROTARGENTUM-SQUIBB.—A compound of gelatin and silver, containing approximately 8 per cent. of silver in organic combination.

Actions and Uses.—See general article Silver Preparations (New and Nonofficial Remedies, 1919, p. 307).

Dosage.—Protargentum-Squibb is used in 0.25 to 5 per cent. aqueous solutions, which should preferably be prepared fresh as required. Solutions are best made by sprinkling the powder on cold water without stirring.

Manufactured by E. R. Squibb & Sons, New York. No U. S. patent or trademark.

Protargentum-Squibb is obtained by the action of silver nitrate on gelatin in the presence of an alkali, precipitation by alcohol and drying in *vacuo*.

Protargentum-Squibb is a chocolate colored, odorless powder, readily though slowly soluble in water, insoluble in alcohol or oils.

An aqueous solution of protargentum-Squibb is alkaline to litmus, but neutral to phenolphthalein. An aqueous solution is not affected by addition of albumin nor by cocaine hydrochloride in weak solution.

When an aqueous solution is treated with sodium chloride, no precipitate is produced although opalescence occurs; no precipitate is formed on the addition of acetic acid.

Dissolve about 1 gm. of protargentum-Squibb, accurately, weighed in about 10 Cc. of distilled water, add 10 Cc. sulphuric acid, U. S., and sufficient powdered potassium permanganate so that the color of permanganate persists for ten minutes (about 2 Gm.). Decolorize the liquid with powdered oxalic acid, add 10 Cc. nitric acid (25 per cent.), heat on a bath of boiling water for fifteen minutes to destroy excess of oxalic acid, cool, dilute with 50 Cc. distilled water, add 5 Cc. saturated solution of ferric ammonium sulphate and then titrate with tenth-normal volumetric potassium sulphocyanate solution. It should show not less than 8 per cent., nor more than 9 per cent. of silver.

Each c.c. of tenth-normal volumetric potassium sulphocyanate solution corresponds to 0.010788 Gm. silver.

SCIENCE AND SURGERY

A recent paper by Horsley[1] on the value of biologic principles in surgical practice concluded with these words:

> Real progress in surgery lies not so much in cultivating the art of surgery and in striving after mechanical dexterity, which is important but can be acquired in a few years, as in the study of biologic principles that concern function, nutrition, metabolism, and repair of tissues, and in the thoughtful application of these principles to every operation and to every method of surgical treatment.

It would be easy to substantiate this significant statement by reference to the history of progress in surgical performance. However, it cannot be reiterated too often, especially to those about to embark on a career in medicine, that technic and curative or operative methods are merely means to an end. Real advance of a permanent sort can rarely be made until there is some appreciation that bodily disorders are in most instances the expression of perverted functions which must be thoroughly understood to be intelligently dealt with, not only in medicine but also in surgery. An accurate knowledge of the location of bodily structures and an ability to alter their position or connections by skilful surgical manipulation may, after all, avail very little unless the mode of physiologic performance of the organs concerned is understood sufficiently well to give promise of satisfactory functioning after the anatomic alterations or reconstructions are carried out. The modern procedures for facilitating wound healing are based not merely on clever manipulations and mechanical devices but, above all, on a careful study of the response of denuded tissues to the operations to which they are exposed. The determination of an optimum reaction of an irrigating solution and the response of the living cells to it require attention quite as well as its antiseptic properties or the route by which it can be made to penetrate wounds. The most skilful operator cannot avoid an insult to injured tissues if, blind to the physiologic principles involved in the nutrition of these living parts, he thinks and acts solely in terms of technic.

In a way it is unfortunate that so much interest is centered by the average advanced student in the purely operative aspects of his work so far as empirical methods are emphasized. The "clever operator" tends to be uppermost in his mind. The student has presumably been inducted into the bearing of a functional point of view during his first two years of study when the methods of the scientist preponderate in all his instruction. He must show proficiency in the sciences concerned with the origin of disease, because their importance is now universally admitted. But, as Macleod[2] has pointed out, when the surgical clinic is reached the methods of the scientist are all too frequently cast aside; and an understanding of disease is sought for largely by the empirical method, namely, by the endeavor to see and examine innumerable patients, to diagnose the case according to the grouping of the signs and symptoms, and to treat it by the prescribed methods of experience. Sir Clifford Allbutt proclaimed in his recent presidential address before the British Medical Association that the new birth of medicine is nothing less than the enlargement of medicine from an art of observation and empiricism to an applied science founded on research.[3] The sooner it is realized that real surgical success rests on physiologically sound thinking as well as on unique manual dexterity, the greater will be the prospect of renewed progress.

NEUROCIRCULATORY ASTHENIA

The careful examinations of thousands of soldiers by skilled medical observers during the past few years have served to bring into prominence various clinical manifestations which might have remained unemphasized or even undiscovered in the casual routine of peace-time practice. The necessity of eliminating the unfit from service and of detecting even latent defects of function has served to focus attention on many items of seemingly trifling import which military experience has gradually brought into more deserving prominence. This is particularly true of abnormalities, or perhaps one should call them inferiorities, of the nervous and vascular apparatus.

In this way a group of symptoms has been designated as neurocirculatory asthenia, sometimes as the "effort syndrome." This has appeared not only abroad but also in our American military camps. In the words of members of a cardiovascular board of the Medical Service of the Army, the signs are increased pulse rate, tremor of the fingers, and cold, moist hands which become cyanosed when dependent. The symptoms are precordial pain with dyspnea and palpitation on moderate exertion, such indications of vasomotor instability as dizziness, flushing and fainting, and a variety of other complaints, all pointing to a state of excessive reaction of the nervous system to psychic or physical strain.[1]

Symptoms of "nervous instability" are frequently and glibly referred to some derangement of thyroid function. A rapid pulse is a manifestation of heightened metabolism. The latter is a concomitant of various sorts of thyroidal upset. But it would be rash to assert that all undue stimulation of metabolism, and therefore all cases of augmented pulse rate, are referable to the thyroid for their genesis. Nevertheless, it seemed worth while to ascertain whether there is any frequent correlation of visible thyroid alteration, such as enlargement represents, with the appearance of the special symptoms and signs of neurocirculatory asthenia. The comparisons drawn by Addis and Kerr[1] at Camp Lewis, American Lake, Washington, on recruits from that state as well as from Oregon and California fail to confirm the prevalent impression that thyroid enlargement is almost constantly present in persons exhibiting the effort syndrome. Thus the development of "toxic goiter" can scarcely be the cause of the syndrome, even in persons with enlarged thyroid. Addis and Kerr assert that the enlargement of this gland in such cases is incidental and not causative. For practical consideration they add that there is no reason why cases of thyroid enlargement with the syndrome should be considered as in any essential respect different from those without thyroid enlargement, nor any reason why the treatment and the disposition of these cases should necessarily be altered by the thyroid enlargement as such.

NATIVITY OF PARENTS AS A FACTOR IN INFANT MORTALITY

Statistics have often become the subject of ridicule, and rightly so, when they have been applied to the problems of human betterment. Indeed, it may be stated with presumable fairness that few medically trained persons are really competent to use statistics in a scientific manner. When, however, the professional statistician "juggles the figures," they gain a sort of recognition which is otherwise rarely accorded to them. These comments are the prelude to a consideration of the high rate of infant morbidity and mortality which still exists in various parts of this country. It has long been evident that any effective program for remedying the existing conditions must be based on a careful analysis of available statistical data. A recently published study by Eastman[2] of the Division of Vital Statistics of the New York State Department of Health has furnished food for thought as to the direction to be taken by future measures for the conservation or betterment of child life. It shows, as might be expected, that where an unfavorable sanitary environment is likely to be found, deaths from communicable, respiratory and gastro-intestinal disease are abundant. This is the case among the foreign-born population, the majority of whom, Eastman points out, are poor, illiterate, without knowledge of English, and almost wholly ignorant of the elements of modern sanitation, and inhabit, as a rule, the most congested districts of the large manufacturing centers. On the other hand, Eastman avers, the superior environment and intelligence of the average native woman is reflected in the comparatively low mortality of her babies from these diseases.

The great majority of deaths of children above 1 month of age are caused by the diseases already mentioned. Despite this contrast between the untutored foreigner and the native stock, it is a statistical fact that in New York State the mortality of babies under 1 month of age is higher among those born to native mothers than among children born of women of foreign nativity. Although the mortality of children in 1916 under 1 year of age born of native women was only 87 per thousand births, compared with 108.4 for children of foreign born mothers, the rate under 1 month for the former was 47.4, as against 45.2 for the latter. About three quarters of the deaths of infants under 1 month of age are due to prenatal causes. Of the total number of deaths occurring in 1916 within the first day after birth, more than 60 per cent. were due to premature birth, 13 per cent. to congenital debility and malformations, and nearly 15 per cent. to injuries at birth, amounting in all to about 88 per cent.

All workers for social betterment realize the beneficent possibilities of efforts to reduce infant mortality where unhygienic factors like overcrowding, improper feeding, imperfect sanitation and other comparable and remediable conditions prevail. The new study just reported indicates that amid our concern for the dangers arising from ignorance and indifference we must not be oblivious to the fact that insanitary environment is not the only matter deserving of serious consideration in any campaign for child welfare. Deaths from premature birth and congenital causes have different explanations, among which venereal disease and alcoholism are to be found. Hence Eastman wisely advises that if the population of any section is discovered to be preponderantly native, the proper course to be adopted should be mainly one of education in regard to prenatal conditions. If it is found to be largely of foreign born stock, it will be necessary to plan principally for a course of instruction in the proper feeding and care of the infant and for the improvement of sanitation. This procedure, Eastman adds, would seem to be both rational and practicable, and should be the basis of all future campaigns for infant welfare that aim at efficiency and success.

WHAT THE UNITED STATES SUPREME COURT THINKS OF FORMULA DISCLOSURE —IN FOODS

On April 14, 1919, the United States Supreme Court handed down a decision of the highest importance to those interested in questions of public health. The question before the court was one dealing with the right of a state to require manufacturers of proprietary foods to print on the labels of their products the names and quantities of the ingredients. This right had been attacked by the manufacturers of a proprietary food, who charged that the state's requirement was a violation of their constitutional guaranties in that it amounted to taking their property without due process of law. This argument was based on the fact that the proprietary food product was made under a secret formula, and that to disclose that formula would cause the manufacturer great and irreparable damage. The Supreme Court's answer to this argument is definite and to the point:

> ". . . it is too plain for argument that a manufacturer or vendor has no constitutional right to sell goods without giving to the purchaser fair information of what it is that is being sold. The right of a manufacturer to maintain secrecy as to his compounds and processes must be held subject to the right of the state, in the exercise of its police power and in promotion of fair dealing, to require that the nature of the product be fairly set forth."

Briefly, the facts in the case were these: The Corn Products Refining Co. of Illinois makes, among other preparations, a proprietary table syrup that is composed of 85 per cent. glucose (euphemistically known as "corn syrup"), 10 per cent. molasses, and 5 per cent. sorghum. This mixture was sold under the proprietary name "Mary Jane." The labels on the tins declared that the product was "A Table Syrup Prepared from Corn Syrup, Molasses and Pure Country Sorghum. Contains Sulphur Dioxid."

The state of Kansas has a good pure food law and, what is equally important, it seems to have officials that will enforce the law. One of the requirements of the Kansas law is that manufacturers of proprietary foods must state on the label the names and percentages of the materials used, and specifically in the case of syrups "the principal label shall state definitely, in conspicuous letters, the percentages of each ingredient, in the case of compounds, mixtures, imitations or blends." As "Mary Jane" was obviously a compound, and as the labels did not give the percentages of the ingredients, the Kansas State Board of Health notified those who were selling "Mary Jane" that unless the syrup was plainly labeled a compound and the percentages of each ingredient were given, there would be arrests and prosecutions. As a result of this action, the Corn Products Refining Company brought action against the members of the board of health, declaring in effect that the requirements of the board were in conflict with the constitution of the United States, both as regards the interstate commerce clause, and as pertaining to the Fourteenth amendment. They also claimed that it was in conflict with the federal Food and Drugs Act.

The case came to trial in a district court, in which the glucose concern won, that court ordering that a perpetual injunction should be issued restricting the State Board of Health of Kansas from interfering with the sale of "Mary Jane." The board of health appealed the case to the Supreme Court of Kansas, which court, having a better appreciation of the interests of the public, reversed the judgment of the district court. The Corn Products Refining Company then carried the case up to the Supreme Court of the United States, with the result that the judgment of the Kansas Supreme Court was upheld. It now becomes a matter of record from the highest court in the land that secret formulas of proprietary foods, at least, are not the holy and inviolable things that the proprietors thereof would have us believe. Slowly the old order passes. The rights of property, held in the past, by the interpretation of the courts, as paramount to the rights of health, are gradually assuming their proper relation in the scheme of a rational state.

THE PREVENTION OF PNEUMONIA BY *INOCULATION*

An able clinician and investigator whose interest has centered chiefly on the pneumonia problem remarked recently that "the more cases of pneumonia he treated the less treatment they got." It was a healthy confession of our present limitation in therapeusis which only adds emphasis to the value of the preventive measures that have been developed during recent years. To this advance American medicine has contributed its full share.

Following the promising but inexact experiments of Wright in South Africa, it will be recalled that Lister[1] carried out prophylactic immunization in a large number of Rand mine workers, using a composite vaccine made from pneumococcus types prevalent in that region. Lister at first tried intravenous injections; later, however, he found that subcutaneous injections were sufficient to establish an immunity against infection. This protection was almost 100 per cent. efficient against the particular types of pneumococci used in the vaccine, thereby justifying the belief that prevention of pneumonia by vaccines was a feasible procedure. We now have available for study the results of two similar series of prophylactic inoculations made at Camp Upton by Cecil and Austin[2] and at Camp Wheeler by

---

S.: An Experimental Study of Prophylactic Inoculation Against Pneumococcal Infection in the Rabbit and in Man, South African Institute for Medical Research, 8: 1916; Prophylactic Inoculation of Man Against Pneumococcal Infections and More Particularly Against Lobar Pneumonia, South African Institute for Medical Research, 10: 1917.

[2] Cecil, R. L., and Austin, J. H.: Prophylactic Inoculation Against Pneumococcus, J. Exper. Med. 28: 19 (July) 1918.

Cecil and Vaughan[3] which seem to confirm the work of Lister.

At Camp Upton Cecil and Austin used a saline pneumococcus vaccine containing Types I, II and III. Of this vaccine three or four doses were given at weekly intervals. The first dose contained three billion organisms, the final doses from six to seven and one-half billion. Some twelve thousand seasoned troops were inoculated, which number represented approximately 40 per cent. of the strength of the entire command. While the period of observation after the inoculation was unfortunately a brief one (ten weeks), definite evidence of protection was made apparent by the fact that no cases of pneumonia of Types I, II or III occurred in the vaccinated groups, while twenty-six cases due to these types of infection originated in the unvaccinated groups. Only seventeen cases of pneumonia of all types (including Type IV and the streptococcic) developed among the vaccinated as contrasted with 172 cases among the unvaccinated men.

At Camp Wheeler Cecil and Vaughan found it possible to immunize virtually 80 per cent. of the total command, but the conditions differed materially from those at Camp Upton in several respects: first, that a large number of the troops were recruits and consequently more susceptible to the disease (the difference in the susceptibility to pneumonia between seasoned troops and recruits has been recently discussed by Opie and his associates[4]); second, that the work was complicated by the influenza epidemic, and third, that a lipovaccine was substituted for the saline vaccine previously used. This vaccine, as described by Fennel,[5] contained the three types of pneumococci in a dosage of ten billion organisms per cubic centimeter and only one injection was required for complete immunization.

The study had to be discontinued when demobilization was begun, but it covered a period of approximately three months. During this time 363 cases of pneumonia of all varieties occurred among the vaccinated men (80 per cent. of the total command) and 327 cases among the unvaccinated (20 per cent. of the command); almost as many, therefore, among the unvaccinated one fifth as among the vaccinated four fifths. Excluding cases that developed within one week after the inoculation, namely, before protection of any kind could be expected to have developed, only eight cases of Type I, II and III pneumonia developed among the vaccinated men. These were all secondary to severe cases of influenza.

When the incidence of the pneumonia among recruits, on the one hand, is studied, it is found that per thousand men the incidence was twice as great for the unvaccinated as compared with the vaccinated recruit. In the seasoned troops, on the other hand, the difference was even greater, for there were almost seven times as many cases among the unvaccinated as among the vaccinated men, an observation that leads Cecil and Vaughan to the belief that the proper time to vaccinate recruits is two or three weeks before they are inducted into service in the camps. As a result of their work they have reached the conclusion that even in civil life, where pneumonia outranks other infectious diseases in the mortality list, inoculation against pneumonia will find a large field of usefulness, especially when relatively nontoxic vaccines such as lipovaccines are available. Their observation, too, that absolutely no evidence exists that such prophylactic vaccination is followed, even temporarily, by a so-called "negative phase" or period of lowered resistance to the disease against which protection is sought is also reassuring.

Current Comment

THE PRUDERY OF THE PRESS

All efforts to diminish the spread of venereal diseases have encountered as a real obstruction a peculiar prudery in the American press. In his recent work on "The American Language" Mr. H. L. Mencken calls attention to the fact that the department of health in New York City in 1914 announced that its efforts to diminish venereal diseases were handicapped because "in most newspaper offices the words syphilis or gonorrhea are still taboo and without the use of these terms it is almost impossible to correctly state the problem." The Army Medical Corps in the early part of 1918 also encountered the same difficulty; most newspapers refused to print its bulletins regarding venereal disease in the Army. "One of the newspaper trade journals thereupon," Mencken says, "sought the opinions of editors upon the subject and all of them save one declared against the use of the two words." One editor placed the blame on the postoffice, and another reported that "at a recent conference of the Scripps Northwest League Editors" it was decided that "the use of such terms as gonorrhea, syphilis, and even venereal diseases would not add to the tone of the papers, and that the term vice diseases can be readily substituted." Mr. Mencken is of the opinion that the most Pecksniffian of American cities is Philadelphia, and he cites as a conspicuous example the change by the *Public Ledger* of the words "a virgin" to "a young girl." When the motion picture entitled "To Hell with the Kaiser" was advertised under government patronage, all of the Philadelphia billboards changed the announcement to read "To H—— with the Kaiser." Most of our readers know the numerous synonyms used by the press for syphilis, among them "blood poisoning," "social evil" and "social disease." Apparently the press has been unable to coin a word for gonorrhea and the subject is merely tabooed. The campaign against venereal diseases depends largely on education of the public. Is the prudery of the press to continue to hinder such education?

FOOD AND HEALTH IN THE ARMY

The lessons of the interrelations between good physique, physical exercise and adequate nutrition, as exemplified in observations made in our army camps are too significant to be forgotten amid the altered interests of peace times. Accurate measurements were made by skilled observers on unusually large numbers of young men and as a result an exceptional amount of statistical information is now available with respect to many factors bearing on personal hygiene. Hildebrandt[1] of the Section of Food and Nutrition, Medical Department, U. S. Army, in a study of the gains made by certain recruits, found that there was an increment of several pounds in body weight, together with an unquestionable increase in the motility of the chest. This was a characteristic indication of the improvement in the physical condition of the men. The study at Camp Pike showed in an illuminating way how the gain in weight is attended with increased food consumption. Owing to the efficient service of the nutritional officers the diet in the Army has become reasonably economical, and the waste of edible food—a source of widespread complaint in the early days of the war—has been greatly reduced. Leftovers from the kitchen are being utilized in subsequent meals, and mess kits are emptied at the table. According to Hildebrandt the average energy value of the food consumed per man per day in the groups thus investigated was 3,700 calories, a figure typical of the consumption found in army messes generally. The demonstration that the typical army mess has furnished a sufficient amount of nutritious food to meet the requirements of active, vigorous young men will permit those concerned with the feeding of large groups in the future to apply these experiences to their own problems.

NO FLIES—NO MOSQUITOES

The United States Public Health Service has just issued, and will supply in quantities, two posters which aim at arousing a general interest in the prevention and control of two insects which are responsible for a great deal of disease in this country. We refer, of course, to the mosquito and the fly. The posters, in addition to enumerating the diseases and losses produced from this source, contain detailed information in regard to the most practical measures for freeing a community from both pests. A good purpose would be served by having both posters freely displayed to focus public attention on the matter. When people realize the unnecessary economic and human loss caused by flies and mosquitoes we may be able ultimately to reach a time when towns and homes will take the same pride in displaying posters announcing the fact that they are free from mosquitoes and flies that they now take in exhibiting Liberty Loan honor flags. As one of the posters of the Public Health Service reminds us, any campaign of this sort must begin as early as practicable, for a pair of flies or mosquitoes hatched in April may give origin to millions by August. The thing to do is to keep the first pair from breeding.

Association News

THE ATLANTIC CITY SESSION

Moving Picture Theater to Show Scientific Work

One of the features of the Atlantic City Session, June 9-13, will be the moving picture theater, a part of the Scientific Exhibit. Casino Hall, on the second floor of the Casino, Steel Pier, has been secured. It is completely equipped with stage, screen, projecting apparatus and seats for 1,000. A continuous exhibit will be held on Tuesday, Wednesday, Thursday and Friday from 9 a. m. to 3 p. m., running through the noon hour, so that Fellows in section meetings will have an opportunity to attend the moving picture exhibit during the noon intermission. A large number of beautiful and interesting moving picture films furnished by the Medical Department of the Army, the Bureau of Medicine and Surgery of the Navy and the U. S. Public Health Service will illustrate the work of the medical officers in the Army and Navy as well as various public health questions. In addition a large number of private exhibitors will demonstrate lantern slides, roentgen-ray plates and moving picture films on various scientific subjects. A half-hour illustrated lecture will be given each day on some phase of the work on nostrums and proprietary preparations of The Journal of the American Medical Association. Admission will be free to all persons wearing the Association button. The program for each day will appear in the *Bulletin*.

Medical Mobilization and the War

Personnel of the Medical Department

For the week ending May 16, there were 15,840 officers in the Medical Corps, a decrease of 1,720 from the previous week. The Medical Reserve Corps contained 1,915 officers. The total number of medical officers discharged since the beginning of the war is 16,302.

Distinguished Service Medal to Col. Frank Billings

Col. Frank Billings, Chicago, M. C., U. S. Army, has been awarded the D. S. M. for "exceptionally meritorious and conspicuous service in the organization and administration of the division of reconstruction of the medical department."

Distinguished Service Awards

Major-General Thomas H. Barry, U. S. Army, presented the Distinguished Service Medal to Burton J. Lee, Col., M. C., New York City, and to Harold E. Foster, Lieut., M. C., U. S. Army, Castile, N. Y., who recently returned after eighteen months' service abroad, was twice cited by the British for bravery under fire and received the British War Cross.

Allied Medical Society of Northern Russia

Some weeks ago the allied medical officers of the troops in northern Russia organized the Allied Medical Society of Northern Russia. Meetings have been held every two weeks. On March 26 a meeting was held at the American Red Cross Hospital in Archangel. Cases were presented and following the presentation of each case occurred an interesting general discussion. The program included presentations by Majors J. R. Longley and W. H. Henry and Capt. C. O. Greenleaf of the Medical Corps, U. S. Army.

Service of Students' Corps Acknowledged

The status of the Students' Army Training Corps as an integral part of the Army has been definitely established by recent action of the War Department in amending the orders concerning the award of the Victory Medal so as to include the members of the S. A. T. C. in the list of those eligible. Following the publication of the order (G. O. 48) concerning

---

1. Hildebrandt, F. M.: Some Physical Improvements in National Army Men Under Military Training, Science 49: 404 (April 25) 1919.

the award of the Service Medal by General March, the War Department was asked for a decision concerning the status of the student organizations. Some communities have asked for an opinion as to whether members of the S. A. T. C. should be included memorials. In reply to these questions the War Department has said that the members of the S. A. T. C. properly inducted into the service were on active duty in the U. S. Army and were an integral part of the land forces. This decision is acknowledgment of the service of the S. A. T. C. by the War Department.

HONORABLE DISCHARGES, MEDICAL CORPS, U. S. ARMY

Note.—In the following list, L. signifies lieutenant; C., captain; M., major; L. C., lieutenant-colonel; Col., colonel, and B.-G., brigadier-general.

Acting Asst. Surg. R. A. JEWETT, proceed to Atlantic City, N. J., for duty in installation of Public Health Service exhibit at the meeting of the American Medical Association.

Acting Asst. Surg. G. C. JONES, proceed to Greenville, S. C., for duty in the Public Health Service Hospital.

Acting Asst. Surg. J. C. TRAVERS, proceed to Greenville, S. C., for duty in the Public Health Service Hospital.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ILLINOIS

Unlicensed Practitioner Guilty.—Mr. Peter Cartsoles of 520 North Green Street, Chicago, was arrested by the Department of Registration and Education of the State of Illinois for practicing medicine without a license. The court found him guilty and paroled him for one year to a probation officer in Chicago.

Personal.—Dr. Charles A. Eames, assistant chief surgeon of the National Soldiers' Home, Danville, for seven years, has been transferred to the central branch hospital of the National Soldiers' Home, Dayton, Ohio.——Robert L. Morris, Major, M. C., Illinois N. G., Decatur, has been placed in charge of the Medical Corps organized at Danville.

The First Blind Massage Class in America.—The Chicago Lighthouse, an Illinois organization for helping the blind, in 1918 instituted for these unfortunates a class in massage, which has recently been graduated. The class was composed of six men and two women, carefully selected from a large group of blind people by Mr. Peter Peel and Dr. Jacob W. Bolotin, Chicago, the blind heart and lung specialist. The training consisted of an eleven month course conducted according to the system used at St. Dunstan's Hostel for the Blind of England, where massage was successfully taught to blinded soldiers as early as 1915. The founder of this institution, Sir Arthur Pearson of London, sent for the use of the American class, fifteen books in revised British Braille. These books are a compilation of the technical knowledge obtained from a digest of the most scientific works written on the subject by such authors as Ashby, Cunning, Halleburton, Hudson, Palmer, Kurre W. Ostrom, G. F. Stout and Dr. Justina Wilson. The students were instructed in anatomy by Dr. Bolotin and received their technical training from Mr. Peel. They were found to be very adaptable to the work and became most efficient masseurs. Mr. Peel plans to take two of the graduates at a time into his office to serve an internship of a few months, during which time they receive a remuneration of from $20 to $25 a week. He requests Chicago physicians to cooperate with him in this worthy undertaking by sending patients to these masseurs, especially poor patients who cannot afford to pay for the services rendered, so that the masseurs may have an opportunity of receiving more practical experience. Further information may be obtained by communicating with Mr. Peel at 20 West Jackson Boulevard; telephone, Harrison 8128.

Chicago

Course in Dietitics.—The Bureau of Dietitian Service of the American Red Cross has arranged through the Chicago Chapter Teaching Center to hold a course in dietetics at hospital training schools for nurses. Any school which has not already a visiting dietitian will be assisted by the Red Cross on application to Mrs. L. P. Mehlig, Dietetics Department, Chicago Chapter Teaching Center, American Red Cross.

Personal.—Dr. Boleslaus Klarkowski has been appointed a member of the board of education for four years.——Dr. Haim I. Davis, Major, American Red Cross, has returned after two months' study of the situation in Poland and Galicia.——Dr. Frank J. Norton has gone overseas for duty with the Y. M. C. A.——Major Samuel J. Walker, American Red Cross, who headed a relief commission into Bulgaria, has returned to his work in Macedonia.——Judge Joseph B. David, in the superior court, May 17, set aside the verdict of $6,500, returned by a jury the previous day against Dr. Daniel A. K. Steele, in a damage suit for $50,000 brought by Miss Dell D. Nichols, who claimed because of an operation performed by Dr. Steele she lost her voice. Judge David held that there was nothing in the evidence which would indicate that the operation was the cause of the plaintiff's misfortune. ——Dr. Haldane Cleminson, charged with the murder of his wife in 1909, and imprisoned in the state penitentiary in Joliet, since 1911, has been recommended to Governor Lowden for discharge from prison.

IOWA

Homeopathic College Discontinued.—It is reported that at the last meeting of the Iowa legislature the College of Homeopathic Medicine of the State University of Iowa was discontinued and an elective chair in homeopathic materia medica and therapeutics was incorporated in the state college of medicine. This chair is to be occupied by Dr. George Royal, Des Moines, former dean of the College of Homeopathic Medicine.

New State Officers.—At the sixty-eighth annual meeting of the Iowa State Medical Society, held in Des Moines, May 7 to 9, under the presidency of Dr. Max E. Witte, Clarinda, the following officers were elected: president, Dr. William L. Allen, Davenport; president-elect, Dr. Donald Macrae, Jr., Council Bluffs; vice presidents, Drs. George C. Stockman, Mason City, and Granville N. Ryan, Des Moines. About 700 members were in attendance at this meeting, and Des Moines was selected as the next place of meeting.

Personal.—Dr. Walter L. Bierring, Des Moines, a member of the National Board of Medical Examiners, has secured passports and will leave next month on a mission to England, France and Italy. The board of which he is a member has been appointed to consult with national examining boards of other countries looking toward the securing of a uniformity of examinations, which will permit the issuance of world certificates.——Dr. Benjamin Thompson, Tama, on May 14, celebrated the fiftieth anniversary of his entrance into the practice of medicine in Tama County.——Dr. James F. Battim has succeeded Dr. Alpheus B. Conaway, as city physician of Marshalltown.——Dr. Loren K. Meredith, Des Moines, has been appointed by the state board of health to superintend the carrying out of the new venereal disease act, which was recently passed by the general assembly.——Pearl Spanswick, Des Moines, has been appointed state bacteriologist. ——David S. Fairchild, Col., M. C., U. S. Army, Clinton, chief surgeon of the Rainbow Division, has returned from abroad.

KANSAS

County Society Organized.—Physicians of Osborne County met at Osborne, May 2, reorganized the Osborne County Medical Society and elected the following officers: president, Dr. James E. Henshall; vice president, Dr. Benjamin F. Chilcott, and secretary-treasurer, Dr. Samuel J. Schwaup, all of Osborne.

State Society Meeting.—The fifty-third annual meeting of the Kansas Medical Society was held in Ottawa, May 7 and 8, under the presidency of Dr. William S. Lindsay, Topeka. It was announced by the president that 651 physicians of Kansas, or nearly one half of the practitioners of the state, have been in the service of the United States in some capacity during the war. Dr. Elmer E. Liggett, Oswego, was elected president, and Hutchinson was selected as the place of meeting for 1920.

MARYLAND

Personal.—Dr. Clement A. Penrose, who has been seriously ill for the past eight weeks at his home in Baltimore, has been removed to the Church Home and Infirmary, where he has undergone a severe operation and is reported as doing well.——Albert G. Singewald, Major, M. C., U. S. Army, Baltimore, who served overseas, has returned and entered U. S. Army General Hospital No. 2, at Fort McHenry, for treatment.

Hospital for Tuberculous Negro.—Plans for a sanatorium for the tuberculous negro, which was authorized by the last legislature, are being developed now by the board of directors of the Maryland State Sanatorium. The legislature appropriated a total of $75,000 to start the work, $50,000 in this fiscal year and $25,000 in the next. The members of the board assume that the state will be reasonable in making future appropriations and expect to have considerably more money to put into the construction of the institution. There is the most vital need for an adequate institution that will care for the tuberculous negro. It is said to be practically settled that the hospital will be located near Baltimore. In this location, the institution can get its water, light and sewage facilities from the city, and thus avoid the expense of building its own plants. A hospital for at least 100 beds at the outset is under consideration.

MASSACHUSETTS

New Hospital.—The new Norfolk County tuberculosis hospital at Braintree Highlands, recently established at a cost of $365,000, has been formally dedicated. The hospital has a total capacity of seventy-five patients although twenty-five additional patients can be installed without overcrowding.

Personal.—Joel E. Goldthwait, Col., M. C., U. S. Army, Boston, who commanded the reconstruction hospital in France under the direction of the Massachusetts General Hospital Unit, has returned to the United States.——Dr. Charles W. Bartlett, Marshfield, has been reappointed medical examiner (coroner) of the Fifth Plymouth District.——Dr. William J. Gallivan, Boston, has been reappointed a member of the health council.——Dr. George L. West, Newton, has been reappointed medical examiner (coroner), and Dr. T. Morton Gallagher, associate medical examiner, for the Seventh Essex District.——Dr. Dudley A. Sargent, Cambridge, widely known expert on physical education, for forty years, director of the Hemingway Gymnasium of Harvard University, has resigned, but will continue to direct the Normal School of Physical Education.——Dr. Seth L. Strong, Marshfield Hills, who has been teaching surgery for several years in the Royal Medical College at Bangkok, Siam, has returned to the United States on account of ill health.——Dr. Bernard W. Carey, Winthrop, epidemiologist of the state department of health, has been appointed director of the division of communicable disease, succeeding Dr. John S. Hitchcock, Northampton, resigned.——Dr. George H. Bigelow, Boston, recently returned after service in the epidemiologic department of the Army in France, has been appointed temporary epidemiologist of the state board of health, succeeding Dr. Carey.

MISSISSIPPI

Mississippi Registration Area.—Official notification has been received by the state board of health that the bureau of vital statistics of the board has been admitted into the federal registration area for deaths, having successfully passed the test requiring 90 per cent. registration.

Personal.—David W. Walley, Major, M. C., U. S. Army, Richton, on duty with the Thirteenth Division, has been promoted to the rank of lieutenant-colonel, and has returned to the United States.——Dr. Robert N. S. Young, Brooklyn, has been appointed all-time health officer for Hattiesburg and Forrest County.——Dr. Walter W. Crawford, Lieut.-Col., M. C., U. S. Army, Hattiesburg, who has been on duty with the American Expeditionary Forces in France for several months, has returned home.

New State Officers.—The annual meeting of the Mississippi State Medical Association was held in Hattiesburg, May 13 and 14, under the presidency of Dr. Walter S. Leathers, dean of the department of medicine of the University of Mississippi. Jackson was selected as the place of meeting for 1920, and the following officers were elected: president, Dr. Felix J. Underwood, Aberdeen; secretary, Dr. Thomas M. Dye, Clarkesdale; treasurer, Dr. James M. Buchanan, Meridian, and members of the state board, Drs. Walter S. Leathers, University; Charles D. Mitchell, Jackson; Thomas F. Elkin, Tupelo; Benjamin L. Crawford, Tylertown, and Harry F. Garrison, Hattiesburg.

MISSOURI

Retroactive Bill Defeated.—A bill was introduced into the Missouri legislature amending the medical practice act so as to require the state board of health to admit to its examinations graduates of a "legally chartered" instead of a "reputable" medical school. The bill was defeated.

Health Conference.—The Springfield chamber of commerce, cooperating with the Missouri Tuberculosis Association, will hold a health-education conference at Springfield, May 29 to June 1. The object of the campaign is to secure instruction in the principles of personal hygiene and household sanitation to all schoolchildren in the state, and in municipal and industrial hygiene and sanitation to students in higher institutions of learning; to ascertain through a scientifically conducted health survey of schools and schoolchildren, especially in rural districts, facts pertaining to the status of the health of schoolchildren and of sanitary conditions under which they live; to determine a feasible plan whereby the health and mental efficiency of schoolchildren may be promoted; and to promote through systematic physical training and playground activities the normal instinct to play, whereby the schoolchild may be assured a sound and enduring body to house a well-trained mind. These objects are to be secured by the detail of one of the five normal schools of the state of a qualified agent as instructor in rural school and household hygiene and sanitation, who will also give like services to students in teacher training course in high, village and rural schools; by the employment of a competent woman to direct state-wide work in the modern health crusade; by the detail, for state-wide service in the universities and colleges of the state, of a man specially qualified in the principles and practice of industrial and municipal hygiene and sanitation; by the employment of a highly trained and experienced director of health surveys, of a state director of school nursing, and of state and district directors of physical training and playground activities.

NEW JERSEY

Eugenic Law Passed.—Under a bill passed by the legislature of New Jersey, a physician's certificate of health has been made a prerequisite to matrimony in the state. The purpose is to prevent any persons from marrying who are afflicted with contagious or social diseases. The bill also provides that a fee for a physician making the necessary examination shall not exceed $2.50, and that county physicians, if called on, shall make this examination without charge to indigent applicants.

Reconstruction of the Industrially Disabled.—A commission has recently been created by act of the New Jersey legislature which has for its purpose the application to the cripples of civil life of those principles for the reconstruction of the disabled in civil and industrial life that have been worked out so successfully under military organization. Governor Edge and the members recently visited United States General Hospital No. 3, Colonia, N. J., to study the work being done there under Major Fred H. Albee, chief of the surgical division of that hospital. Governor Edge has appointed Major Albee chairman of the rehabilitation commission.

NEW YORK

New York City

Opposition to Health Insurance.—At a meeting of the Harlem chamber of commerce and the physicians' league, held on May 8, resolutions were passed endorsing the action of the Medical Society of the State of New York in instructing its delegates to oppose compulsory health insurance at the approaching annual session of the American Medical Association.

Hotel Opens Hospital.—The management of the new Hotel Pennsylvania has opened a hospital fully equipped, with operating room and roentgen-ray apparatus for the use of its more than 2,000 employees. The hotel has conducted a clinic for several months and has treated an average of sixty patients daily. The hospital will be in charge of Dr. Joseph Darwin Nagel, assisted by a staff of visiting physicians and surgeons and a corps of trained nurses. A visiting nurse will also be employed to look after the home conditions of patients.

Personal.—Dr. St. Clair Smith is to be the guest of honor at a dinner to be given at the Hotel Astor in celebration of his fifty years in the practice of medicine in this city.——Dr. Francis M. McMahon, attached to the staff of the Knickerbocker Hospital, was thrown to the pavement recently and sustained severe contusions and internal injuries, when the ambulance in which he was responding to a sick call collided with an automobile truck.——Royale H. Fowler, Brooklyn, Major, M. C., U. S. Army, who recently returned after service with Base Hospital No. 6, at Beaune, France, has been assigned to duty with General Hospital No. 21, Fox Hills, N. Y.

Charities Conference.—The tenth annual meeting of the New York City Conference of Charities was held, May 13 14 and 15, under the presidency of Dr. Franklin Chase Hoyt The questions discussed related to public health, war labo problems and public charities. Health Commissioner Copeland spoke of public health problems; Justice Cornelius F Collins discussed the problem "After the Saloon, What?" Dr. Pearce Bailey spoke on "The Problem of the Feebleminded in New York." Justice Collins expressed the opinio that an increase in indulgence in habit-forming drugs i almost certain to follow after prohibition and that legislation should be such as to permit medical judgment to prescribe alcohol. Dr. Walter H. Conley spoke on "The Unification and Control of Public Hospitals." He believes that an ideal control of public hospitals could be obtained by establishing a department of hospitals under the jurisdiction and direction of a commissioner, instead of the present system, which leaves the hospitals under three distinct departments of the state government. Charles H. Johnson, secretary of the state board of charities, spoke on "Cooperation and Relation of Public and Private Agencies."

PENNSYLVANIA

Philadelphia

Personal.—Samuel Calvin Smith, Major, M. C., U. S. Army, formerly an instructor in the Jefferson Medical College, arrived from France, May 3. While overseas, he was stationed at a group of evacuation hospitals in the advance area of Bazoilles-Sur-Mese, later was transferred to Marseilles, where he was appointed chief of the medical service. ——Dr. Florence Chapman Child has returned from France, where she spent eighteen months with the division of child hygiene of the American Red Cross.——Drs. Alice Weld Tallant and Maude Kelly, formerly of the staff of the Women's Medical College, have been awarded the croix de guerre and Service de Sante decorations. They are the only American women given the ranks of major in the French army. Dr. Tallant went overseas as a director of the Smith College relief unit.

Postgraduate Course in Social Service Work.—With the cooperation of the Visiting Nurses' Society, the Pennsylvania School for Social Service opened a postgraduate course in public health nursing. The four month course for those wanting immediate preparation will be followed by a nine month course beginning September 16. The shorter course is designed to give practical training, experience in the fundamentals of public health nursing with special emphasis on the social and educational aspects. Two months are spent with the Visiting Nurses' Society under careful supervision work, including general visiting, prenatal and postnatal care of babies. One month will be spent by each student in special work under the direction of a district secretary of the Philadelphia Society for Organizing Charity. There will be a period spent in infant welfare work, including practice in health centers, follow-up work in homes, and study of the tuberculous in the tuberculosis clinics.

CANADA

Laval University Granted Separation.—Laval University, Montreal, has been granted, by special decree of the Pope, separation from Laval University, Quebec City. Hereafter it will be known as the University of Montreal.

Personal.—Dr. Arthur Vallée, Quebec City, has been appointed a consultant by the University of Toronto, to the board of the Connaught Antitoxin Laboratory, succeeding the late Dr. Emmanuel P. Lachapelle, Montreal.

Oxford Medical Association.—The Oxford County (Ont.) Medical Association has elected the following officers: president, Dr. Jethro W. Counter, Ingersoll; vice president, Dr. Weston Krupp, Woodstock, and secretary-treasurer, Dr. George M. Brodie, Woodstock.

Gift to University of Toronto.—The department of medicine of the University of Toronto is to be the recipient of a gift of $25,000 a year for a period of twenty-five years from Sir John and Lady Eaton. This is to provide for a full-time clinician in the department of medicine and a half-time clinician in pediatrics.

Hospital at Alberta.—Arrangements have been completed for the building of a tuberculosis sanatorium at Bowness Park, Calgary, Alta. The building is to be a joint federal and provincial one, with 100 beds for soldiers and seventy-five beds for civilians. The total cost is $524,079, of which the province pays $217,000. After five years the hospital becomes the property of the province.

Queen's Endowment.—The $1,000,000 endowment fund for Queen's University now lacks only $12,000 of being completed. The late Chancellor Douglas, New York, willed $500,000 to the university on condition a like sum was raised from other sources. Some months ago the Carnegie Foundation offered $250,000 on the understanding that the remaining $750,000 be secured by May 15, but the Foundation has had the time limit extended to end of May.

Postgraduate Courses for Medical Officers.—The medical faculties of McGill and Toronto universities, according to report, have resolved to give summer postgraduate courses, especially adapted to meet the needs of returning medical officers. These courses are planned to begin about the middle of June and to extend over a period of three months. Only a nominal fee, to cover the cost of material, will be charged and the services of the teachers will be gratuitous.

LATIN AMERICA

Hookworm Disease in Cuba.—According to a report recently published by Dr. J. F. De Pazos of Havana, there is urgent need of a campaign against hookworm disease in that island, as previous foci have increased and new ones have appeared. Laboratory examinations made in previous years show that the disease prevails in various parts of the island, and especially in three towns, namely, Viñales, Los Palacios and Cabaiguán. According to him, malaria is again becoming a serious problem on the island, especially in the western part, and the statistics relative to typhoid show a greater degree of infection than that existing in Europe and the United States. A league against malaria, hookworm disease and rural typhoid was organized in Cuba in 1917.

Sanitation Work in Uruguay.—The Uruguayan government has been authorized to execute sanitation work, consisting of water and sewerage services or water only, in fifteen cities. The work will be contracted for by cities or groups of cities by public bidding to which national and foreign concerns will be admitted. The work will be paid for by an issue of sanitation bonds bearing 6 per cent. interest and 1 per cent. annual accumulative amortization. The use of drinking water at the rate of 100 liters (26.4 gallons) per day will be compulsory for every house and lot, whether inhabited or not, where canalization passes. The rate for supplying drinking water to the public shall not exceed 15.51 cents per 1,000 liters. It is estimated that the total cost for these fifteen cities will be $12,000,000. In addition to this sum, $4,000,000 will be spent for sewer construction in four districts of Montevideo.

Influenza in Brazil.—As elsewhere, the pandemic of influenza, when it reached Brazil, found the public health authorities entirely unprepared to cope with it. The blame for having permitted the entrance of the disease was placed on Dr. Carlos Seidl, who had been the director of public health from Jan. 15, 1912, until Oct. 17, 1918, when his resignation was requested by the secretary of the interior, because of the criticisms made of Dr. Seidl's apparent inability to prevent first the introduction of the disease and later its spread. In the *Revista Medico-Cirurgica do Brazil* for October, November and December, Dr. Seidl defends his administration of public health affairs and shows that he did all he could with the limited resources at his disposal. In the December number, he reviews his whole term of office and describes the work accomplished by him when he took the position left vacant by Dr. Oswaldo Cruz, the leader in the campaign against yellow fever in Brazil. In concluding, Dr. Seidl quotes the following words, which explain the difficulties he encountered and state the reason he failed to accomplish more:

> It has been shown that sanitary conditions in Brazil depend exclusively on the appropriation of the necessary funds by the government. All the endemic and epidemic diseases are known, and if funds are available there is no doubt as to the success of a prophylactic campaign against them.

GENERAL

Applicants for National Board Certificate.—Sixty-five applicants have been duly qualified to take the National Board examination to be held, June 2-7, 1919, at Philadelphia.

Library Association to Meet.—The twenty-first annual meeting of the American Medical Library Association will be held at Atlantic City, June 9, at 3 p. m., under the presidency of Dr. William Browning, Brooklyn.

Physician's Prescription Required for Venereal Disease Remedies.—According to the *Social Hygiene Monthly*, more than 23,000 druggists of this country have pledged themselves not to sell remedies for venereal diseases over the counter without a physician's prescription.

Antivenereal Disease Campaign in Cuba.—On request of the commander in chief of the Atlantic fleet, a field representative of the social hygiene division of the commission accompanied the fleet to Guantanamo Bay, Cuba, to introduce the program of educational work on venereal diseases.

Hygiene Monthly Discontinued.—With the April, 1919, issue, the *Social Hygiene Monthly* came to an end. Information on the progress of the campaign will be continued especially in the publications of the American Social Hygiene Association and through *Public Health Reports*, the official organ of the U. S. Public Health Service.

Chemical Industries Exposition.—The annual exposition of chemical industries has been changed from its usual place of meeting, New York City, and will be held this year at Chicago in the Coliseum and First Regiment Armory, during the week of September 22. The exposition will be a demonstration in itself of the ability of the United States to maintain chemical independence. Besides the exhibits, the Chicago section of the American Chemical Society is planning a scientific program for the visiting chemists.

National Examining Board Visits Europe.—A committee of the National Board of Medical Examiners, appointed by the chairman, Surg.-Gen. W. C. Braisted, U. S. Navy, consisting of Louis A. La Garde and Victor C. Vaughan, Colonels, M. C., U. S. Army, and Dr. Walter L. Bierring, Des Moines, Iowa, will sail for Europe immediately after the meeting of the American Medical Association at Atlantic City, N. J., to confer with the conjoint board of England, Ecole de Médecine, and Examining Board of France, for the purpose of gaining international recognition for American medicine, on the basis of the certificate of the national board. The committee will remain abroad two months.

Edith Cavell Hospital.—Col. Antoine Depage, professor of surgery at the University of Brussels, and head of the Belgian Red Cross, has arrived in this country and will attend the meeting of the A. M. A. His object is to thank people who contributed to the Belgian relief fund in response to appeals made by his wife, who lost her life on the Lusitania while returning from this mission. Colonel Depage has also announced his plans for building a memorial hospital at Brussels to bear the name of Edith Cavell, who for eight years prior to the outbreak of the war was matron of Colonel Depage's private clinic in Brussels, and of his wife Marie. Lloyd George has already started a fund in England which will defray half the expense of this institution. Colonel Depage hopes to raise the remainder in the United States.

Victory Number of Michigan State Journal.—The May issue of the *Journal of the Michigan State Medical Society* is a "Victory" number. It contains 314 pages and is bound in a very well designed and well executed cover printed in colors. The contents consists of the call and program for the annual meeting of the state society, together with other information regarding the place of meeting, etc., which is likely to prove of interest to the membership, and a complete "Roll of Honor" of those members who were in the government services during the war. Photographs of several hundreds of these doctors are published, together with photographs of the society's officers, groups of nurses who have been in service, various hospitals of the state and other matter bearing on the war activities of Michigan.

Red Cross Recreation Program.—The Red Cross is devising an organized recreational program for the men in the government hospitals throughout the United States. As the government has provided the best surgical skill and medical care for the physical welfare of the soldier and sailor, so the Red Cross is offering to him the most intelligent guidance for his leisure. Dr. Albert K. Fretwell, head of the Department of Recreational Leadership of Teachers' College, Columbia University, has made a tour of the reconstruction hospitals, traveling under the joint direction of the Surgeon-General's Office and the bureau of camp service, department of military relief of the Red Cross. The Red Cross has arranged for every variety of sport in which the convalescent men can participate and acts in cooperation with the department of physiotherapy in order that each man, according to his therapeutic needs, may be given the opportunity for the best physical training.

Bequests and Donations.—The following bequests and donations have recently been announced:

United Charities of Chicago, $10,000; Chicago Orphan Asylum, $8,000; Women's, Wesley, and Presbyterian hospitals each $5,000, by the will of Henry Botsford, Chicago.

Lynn, Mass., Hospital, $10,000 by the will of Walter H. Breed, Lynn.

Natchez, Miss., Hospital, a donation of $15,000 by Mrs. J. M. Carpenter, Natchez.

Presbyterian Hospital, Philadelphia, for the maintenance of a free bed, American Oncologic Hospital, Philadelphia, for the study and treatment of cancer, and Philadelphia Home for Incurables, each $5,000, and Rush Hospital for Consumptives and Free Hospital for Consumptives, Philadelphia, $2,500, by the will of Mary E. Stewart, Philadelphia.

College of Physicians of Philadelphia, a portrait of Michael Leib, one of the founders; Children's Hospital of Philadelphia, $4,000; Philadelphia Home for Incurables and Maternity Hospital, each $5,000; and contributors of Pennsylvania Hospital, $10,000, by the will of Thomas Shelton Harrison.

A New Medical Publication.—The first issue of *Modern Medicine*, a publication to be devoted to "the application of medicine and allied sciences to industrial efficiency and national health," has just appeared. It includes the *Interstate Medical Journal*. It is under the editorship of Drs. Alexander Lambert and S. S. Goldwater and under the managing editorship of Mr. John A. Lapp, who was formerly executive secretary of the health insurance commission of Ohio. The magazine aims to be a clearing house for progress in social medicine. It is well departmentized. Editorials appear under "Notes and Comments"; some excellent original articles under the heading "General Articles;" original papers on industrial medicine under "Medicine and Industry;" and under "The Nation's Health" appear such articles as "Good Roads and Health," "The New Public Health," "Schools Want Uniform Health Courses," "Capitalizing Health Knowledge." The other departments are: "Current Problems and Social Medicine," "The Month in Medicine," abstracts and book reviews. News items appear in the form of fillers. This magazine is well and artistically printed, following in its general plan *Modern Hospital*, issued by the same publisher. If succeeding numbers measure up to the initial one, this journal should be a valuable addition to American medicine.

Sir Arthur Newsholme Becomes Professor of Hygiene in Johns Hopkins School of Public Health.—Sir Arthur Newsholme, K.C.B., who has come to the United States following the closing of the international Red Cross conference at Cannes, France, in which he took a prominent part, has accepted the chair of hygiene in the new School of Public Health of the Johns Hopkins Medical School. The appointment, we understand, is tentatively for the coming year only. Since early in May Sir Arthur Newsholme had been taking part in child welfare conferences as the guest of the Children's Bureau of the Department of Labor. Sir Arthur was, until late in 1918, chairman of the Local Government Board of Great Britain, being succeeded temporarily by Mr. Hayes Fisher and more recently by Sir Auckland Geddes. Dr. Newsholme received the degree of M.D. from the University School of Medicine in 1880, the certificate in public health in 1885, and the F.R.C.P., London, in 1898. For many years he has been associate editor of the *Journal of Hygiene*, an examiner in state medicine in the University of London and an examiner in preventive medicine in the University of Oxford. He delivered the Milroy lecture of the Royal College of Physicians in 1895, his subject being "Natural History and Affinities of Rheumatic Fever." Some of his more important recent publications have concerned "Influenza from the Public Health Standpoint," "Child Mortality," "Tuberculosis and War Conditions," "The Use of Colonies in the Treatment of the Tuberculous" and many other subjects of interest to preventive medicine.

FOREIGN

Influenza in India.—Dispatches from London state that almost 5,000,000 persons have died in British India from influenza, and that fully 1,000,000 persons are believed to have died in the native states from the same cause. The deaths from influenza are estimated at 20.6 per thousand.

Warned Against Typhus Spreaders.—All over Germany notices are being posted warning the population against lice as bearers of typhus and other diseases. The increase in typhus fever is said to be due to the failure of the authorities to delouse the German soldiers returning from Russia.

Vaccination in Spain.—The success obtained with the vaccination measures enforced in the province of Madrid has induced the government to order the governors of all the provinces to institute immediately a vaccination campaign similar to the one conducted in Madrid, which was reported at length in THE JOURNAL for April 12, p. 1091.

Influenza in Spain.—In view of the reappearance of influenza, this being the third wave of the disease, the government has ordered the provincial inspectors to keep track of the disease and to report immediately those communities where the local physicians cannot cope with existing conditions, so that physicians may be ordered for service there from other places.

American Students at the University of Bordeaux.—The *Journal de Médecine de Bordeaux* relates that there are sixty medical students among the 300 American soldier-students now enrolled at the University of Bordeaux. Professor Armstrong is in charge of the American contingent—*nos jeunes amis au costume kaki*, as the journal calls them—and the American contingent already has its special weekly. Its title is *Voilà*, while the 1,200 American students enrolled at Toulouse have a weekly entitled *Qu'est-ce que c'est?* Our exchange relates that the students at Bordeaux represent forty-four states, besides one each from Nicaragua and Canada. Harvard leads in the number of its alumni, with 14; Chicago next with 9, Yale with 7.

Belgian Physicians Who Have Died During the War.—The *Paris Médical* gives a list of the members of the profession in Belgium that have not survived the war. Among them are Drs. Dubois-Havenith, father and son; Dr. Camus, burgomaster of Andenne, shot by the Germans; Prof. Van Gehuchten and Prof. de Winiwarter, both of international fame; Dr. Masoin, secretary of the Belgian Académie de médecine; Drs. Heynen, Boulengier and Van Dam, former presidents of the Féderation médicale; Dr. Rommelaere, professor emeritus of the University of Brussels; the surgeon, Van Engelen; Dr. G. Corin, professor of legal medicine at Liége, and nineteen other physicians. Dr. Dubois-Havenith presided at the International Preventive Congress held at Brussels some years ago.

Deaths in the Profession Abroad.—Dr. **R. Fusari**, professor of anatomy at the University of Turin and formerly incumbent of the chair of histology at Messina, aged 62. His works on histologic and embryologic topics won several prizes offered by scientific societies at home and abroad, and his set of anatomic models are said to be superior to anything in that line in other countries.——Dr. **C. Flensburg**, president at one time of the Swedish Medical Association, a leading internist of Stockholm, aged 63. His work, "Why Malaria Has Disappeared from Sweden" attracted much attention, as also his historical study of the sanitary statistics of the Stockholm garrison. He has also published numerous communications on pediatrics and internal medicine in general.——The *Nederlandsch Tijdschrift* mentions the death of Prof. **H. Aronson** of Berlin, pediatrist and serologist, aged 53.

LONDON LETTER

LONDON, April 30, 1919.

Euthanasia

The question as to whether physicians should have the power to terminate painlessly lives which have become a burden from incurable disease has been debated from time to time. It has arisen once more. An inquest was held in London on a man who stabbed himself in the heart. He had said that it was a pity physicians could not put patients like himself suffering from an incurable disease out of their misery. The coroner, Mr. Ingleby Oddie, remarked that we had not yet come to the stage of civilization which allowed this course, but he had no doubt that the time would come when painless euthanasia would be permitted in such cases. A verdict of "suicide while of unsound mind" was returned. Some days later an inquest was held on a man who suffered from consumption and shot himself through the heart. He had been very depressed because he was incurable and had read and called attention to an article in the daily *Mail* on the previous inquest, which was entitled, "Doctors' Right to Kill." A discussion of the question followed in the press. The medical profession showed itself almost unanimous in opposing the coroner's suggestion. A well-known physician and member of Parliament, Lieutenant-Colonel Raw, said that no physician would accept such a responsibility, for medical science was not an exact science. New discoveries were constantly being made, and a patient that was regarded as incurable today might be cured tomorrow. It was a physician's whole business to prolong life to the last, and to save the sufferer, as far as possible, from physical and mental pain. Once an alteration was made in that conception of a physician's duty, the whole public confidence in the medical profession would go. Again, to illustrate the impossibility of the proposal, suppose it was admitted that incurables might be killed, when would they be killed? A man with a disease might be as incurable in the early stages as he was in the later. He might be able to live for several years. Was he to be killed at first, or in the terminal stages of the disease? Lieutenant-Colonel Raw said that he had known many a case of men who were condemned to death by leading specialists and who had completely recovered. He considered that the proposal was utterly impossible. Capt. W. E. Elliot, another physician and member of Parliament, was equally emphatic. He instanced the cases of men suffering from incurable diseases who had produced discoveries or done work of immense value to the human race in the last few weeks of their lives. Were such men to be exterminated? Might not the physician, in condemning a man to the lethal chamber, be robbing humanity of the possibility of a great product of such a man's brains? Moreover, once the right to death of incurables, with their own consent, had been admitted, the next step would be an admission of the right of other people to decide for them. Then the physician would become at once a suspect, and would lose the confidence of every one of his patients.

Septicemia an "Accident"

As has been often illustrated in previous letters to THE JOURNAL, the Workmen's Compensation Act is so widely drawn up that almost anything which can happen to a workman is held by the courts to be an accident. The following important case has recently been decided in the House of Lords, the highest court in this country. The widow of a workman appealed from a decision of a lower court on the following circumstances. He was employed in the handling and bagging of artificial manures, which were composed largely, or wholly, of bone dust. Jan. 31, 1916, while at work, he became ill with blood poisoning, from which he died, February 16. This illness was due to infection by streptococci and staphylococci. The point of infection was a scratch or abrasion on the skin of the left leg. It was not proved when or how he received this. It was impossible to say with certainty when the infection occurred, though it was probably some days before he became ill. The streptococci and staphylococci were present in large numbers in the bone dust which he had to handle, but they were also to be found in decaying matter, in dust, and in the air, although in a much lesser degree. They might be found on the skin and clothes of persons of uncleanly habits. The arbitrator was satisfied, as the result of the medical evidence, that the infection which caused the illness and death of the workman was derived from the poisonous germs contained in the bone dust which he handled in the course of his employment, and he so found in fact. The case then came before a court, which decided that there was no evidence on which the arbitrator was entitled to find that death was caused by "an injury by accident arising out of and in the course of the workman's employment" within the meaning of the act.

In the House of Lords the Lord Chancellor gave the following judgment, with which three out of four other judges who formed the court agreed. In his opinion the judgment of the lower court could not be supported. The matter was concluded by authority. In a previous case that house had decided (in 1905) that the assault of a bacillus on a workman proceeding from the wool on which he was working, and affecting him with mortal anthrax, was an accident, and that the consequent and fatal disease was an injury. In that case, therefore, the essentials of the composite phrase "injury by accident" were satisfied. That decision might easily prove, with the development of scientific discovery, to be one of far-reaching importance. When the previous case was decided the area conceded by contemporary science to idiopathic disease was much larger than at present, and the area of disease traced to infection by bacilli had correspondingly grown.

Influenza in India

The preliminary report of the sanitary commissioner to the government of India on the influenza epidemic of last autumn has just been published. The epidemic assumed the proportions of a national calamity; no country suffered so severely as did India. In British India, influenza was responsible for a death roll of approximately 5,000,000, and it is unlikely that less than 1,000,000 deaths occurred in the native states. The central, northern, and western portions of India were the worst sufferers. The hospitals in the Punjab were choked so that it was impossible to remove the dead quickly enough to make room for the dying. The streets and lanes of the cities were littered with dead and dying people. The postal and telegraph services were completely disorganized; the train service continued, but at all principal stations dead and dying people were being removed from the trains. The burning ghats and burial grounds were literally swamped with corpses, while an even greater number awaited removal. The depleted medical service, itself sorely stricken by the epidemic, was incapable of dealing with more than a minute fraction of the sickness requiring attention. Nearly every household was lamenting a death, and everywhere terror and confusion reigned. No part of the Punjab escaped. The total estimated influenza mortality during October and November amounted to 816,317, which is 4.2 per cent. of the Provincial population. The poor and rural classes suffered most. The Provincial Sanitary Commissioner attributed this to the fact that such classes were adversely affected by economic conditions resulting from the war and failure of the rains. Food prices were high, milk was scarce, and blankets and warm clothing very difficult to obtain. However, the incidence of the disease was very high among the well-fed British troops in India, greater in fact, among them than among the Indian troops.

Salaried Hospital Staffs

There is reason to believe that the new departure (The Journal, April 12, p. 1091) initiated at the London Hospital—the appointment of whole-time salaried physicians and surgeons, instead of honorary consultants—is likely to be adopted by several of the other great medical schools in London. St. Bartholomew's and Guy's are considering schemes in relation to preventive medicine. The new movement is a great revolution in the medicine of this country. Departments will be set aside for the intensive study of particular diseases, and this study will absorb the whole energies of research workers.

PARIS LETTER

Paris, May 1, 1919.

Health of Schoolchildren in Occupied Territory

At a recent meeting of the Société de pédiatrie, Drs. Génévrier and Heuyer directed attention to the impaired health of the children living in the territory which was invaded by the enemy troops. In the Ardennes especially, the food of the children was woefully deficient, being far from sufficient for their needs. Nurslings had been deprived of milk and flour of good quality, and were forced to eat panada (bread or crackers covered with boiling water) prepared with war bread. Children from 7 to 10 years of age received a very deficient albumin and fat ration. Furthermore, the lodgings were all more or less contaminated by the German troops, and the inhabitants of all ages still continue to sleep on straw infected by vermin. Infestation with lice is very prevalent and from 50 to 60 per cent. of the children are suffering from itch. Children aged from 11 to 12 years have been compelled to do forced labor, which, while not always overtaxing, has, nevertheless, subjected them to the inclemency of the weather, from which they have suffered. Besides these bad physical conditions, other factors affecting their intellectual and moral life have entered in and help to account for the retarded development of these children. They have been set back about eighteen months in development. At school, in the primary grades, cases of anemia and rickets are very numerous. The children of the more advanced grades are all affected by pathologic conditions more or less grave which have been badly taken care of, and many of them present adenopathies. Génévrier and Heuyer urged the immediate institution of corrective measures, and pointed out that the medical services of the various health organizations are far from being in position to cope with conditions. School inspection is needed; school canteens and shower baths should be provided.

Division of Spinal Cord by a Hidden Bullet

Drs. Georges Guillain and J.-A. Barré recently reported to the Société de neurologie an unusual case in which the spinal cord was involved, but for which no cause was discovered in spite of repeated examinations made. A young soldier quartered in rest billets far from the firing line, was seated talking to his comrades. Suddenly he felt a severe pain in the back in the dorsal region and on attempting to get up was unable to arise. He was taken to an evacuation hospital, and from there he was referred to a neurologic service with a diagnosis of transverse myelitis. Reexamination confirmed the presence of a complete paralysis with anesthesia, abolition of tendon reflexes, plantar, cutaneous and flexion reflexes, and sphincter disturbances. Yet there was no apparent injury in the dorsal region nor any painful pressure point along the spinal column. Roentgen-ray examination, however, disclosed a bullet imbedded, point first, in the body of the seventh dorsal vertebra for a distance of 5 cm., one half the depth of the vertebral body. In spite of operative intervention, the man died a few days afterward. The necropsy revealed a division of the spinal cord at the level of the sixth and seventh dorsal vertebrae. Only a slender piece of the left posterior column of the cord maintained its continuity.

This is the only case seen by the reporters in which a wound of the spinal cord by a bullet was not recognized as such. The wound was sustained far from the firing line; there was no external hemorrhage; it was unrecognized by the regimental surgeon, the ambulance surgeons and the neurologists. The point of entrance was almost invisible. The roentgen-ray examination was the only thing that cleared up the situation and explained the nature of the paralysis. It was not ascertainable from what position the bullet had been fired. The bullet had made a physiologic section of the cord, giving rise to symptoms of a complete recent anatomic section. The tendon reflexes were abolished and the cutaneous plantar reflex determined the free flexion of the toes to the right or to the left.

Compulsory Notification of Tuberculosis

The Société médicale des hôpitaux de Lyon, having discussed this question fully, is of the opinion that open cases of tuberculosis should be recorded, in conformity with the bill of Jan. 16, 1919, provided proper measures for the treatment and prophylaxis of tuberculosis be instituted to take care of the large number of patients resulting from such a procedure, and the decree requiring the isolation of tuberculosis patients in hospitals shall be enforced at once. In the absence of such provisions, the society believes that the law will prove ineffective and therefore must withhold its approval.

Tuberculosis and Venereal Disease Prophylaxis

The minister of marine has appointed a commission which will study the question of tuberculosis prophylaxis in the navy and will suggest measures to prevent and combat the development of this disease. Another commission will take up the prophylaxis of venereal diseases in the navy.

International Red Cross Conference

This conference has been held, and a committee charged with this work has published reports of the work done by the sections on tuberculosis, malaria and venereal diseases. The first of these reports contains the conclusions reached by those interested in the campaign against tuberculosis. The following points are considered to be fundamental: (1) dispensaries proportionate to the needs and provided with laboratories and professional visiting nurses who will care for the patients; (2) systematic inspection of schools; (3) hospital care for advanced cases; (4) accommodations in sanatoriums; (5) popular educational propaganda concerning tuberculosis.

The section on malaria has suggested the establishment of an international bureau which, through the assistance of the various Red Cross societies, will effect cooperation with the national agencies charged with the control of malaria. It would be the duty of the bureau to keep abreast of the progress of studies in various countries and associate itself with all existing organizations for the purpose of controlling this disease. It is recommended that a study be made of the geographic distribution of malaria, with the demonstration of means of control, in which connection cooperation with government services is indispensable, for it is really a governmental function.

The section on venereal diseases recommends the organization of entertainments, social and athletic programs, early marriage, isolation of infected persons, systematic preventive treatment, suppression of prostitution, establishment of laboratories, clinics, free consultations, etc.

Marriages

George Adolphus Harris, Jr., Lieut., M. C., U. S. Army, Pittsburgh, on duty in the office of the chief surgeon, Base Section No. 3, S. O. S., London, England, to Miss Sibyl Maude Burton of Walton-on-the-Hill, Stafford, England, February 17.

George Louis Vogel, Capt., M. C., U. S. Army, Boston, on duty at Camp Sherman, Chillicothe, Ohio, to Miss Mary Jane Samuel of Wellston, Ohio, May 2.

Bynum McWhorter Works, Brownsville, Texas, to Miss Anna Lee Konyak of Alta Loma, Texas, at Philadelphia, May 1.

Wyman George Hough, Sibley, Iowa, to Miss Agnes Mai, Marty of Monroe, Wis., at Bismarck, N. D., March 12.

Edson Erwin Blackman, Charlotte, N. C., to Miss Gertrude McWilliams of Raleigh, N. C., April 23.

Elsie Rau Treichler, Germantown, Philadelphia, to Mr. Hiram Ready of Philadelphia, May 1.

William Hamilton Dulaney to Mrs. Emma N. Wells, both of Lynchburg, Va., April 30.

Clarence E. Neipling, to Miss Mable E. Bright, both of Philadelphia, April 30.

Deaths

Frederick Russell Sturgis, Boston; Harvard Medical School, 1867; aged 74; lecturer on venereal diseases from 1874 to 1880, and professor of diseases of the genito-urinary organs and venereal diseases from 1880 to 1882 in the New York University; president of the Medical Society of the County of New York in 1881; visiting physician to the Charity Hospital from 1873 to 1893; a fellow of the New York Academy of Medicine; author of several works and monographs on his specialty; died at his home, May 6.

Angelo Festorazzi, Mobile, Ala.; University of Alabama, Mobile, 1887; aged 54; a member of the Medical Association of the State of Alabama and Association of Military Surgeons of the United States; formerly first lieutenant and assistant surgeon, Alabama State National Guard, and assigned to the First Infantry; a specialist in dermatology; died at his home in January from chronic nephritis.

Frederick Allen Williams ⊕ New York City; Albany (N. Y.) Medical College, 1892; aged 48; medical adviser of the insurance fund of the state industrial commission; for two years a member of the staff of the Hudson River State Hospital, Poughkeepsie; who was injured by the overturning of his automobile near Absecon, N. J., April 26; died in Atlantic City, N. J., May 1, from his injuries.

William A. Hocker, Kemmerer, Wyo.; Bellevue Hospital Medical College, 1868; aged 72; local surgeon for the Oregon Short Line, and health officer of Lincoln County, Wyo.; who had served in both houses of the Wyoming legislature, and was for three years superintendent of the Wyoming State Hospital, Evanston; died in Omaha, April 30, from chronic nephritis.

William A. Morrison, Struthers, Ohio; Western Reserve University, Cleveland, 1881; aged 63; vice president of the Struthers Savings and Banking Company, a member of the first village council, and postmaster for twelve years; died at the home of his daughter in Struthers, May 6, from pneumonia.

Frederick Weisbrod ⊕ Brooklyn; New York University, New York City, 1890; aged 55; a specialist on gynecology; attending gynecologist to the Wyckoff Avenue, Heights and German hospitals, Brooklyn, and consulting gynecologist to the new Utrecht Hospital; died in Philadelphia, May 9.

Nathaniel Harris Kirby, Burdett, N. Y.; New York University, New York City, 1884; a member of the Medical Society of the State of New York; lecturer on dermatology in Denver Medical College from 1889 to 1891; died at his home, March 2, from acute dilatation of the heart.

George M. Getze, Tarentum, Pa.; Hahnemann Medical College, Philadelphia, 1877; aged 64; one of the founders and president of the Allegheny Valley Hospital, Tarentum, and former president of the Tarentum board of education; died in a sanatorium at Clifton Springs, N. Y., May 3.

George S. Burruss, Augusta, Ga.; Meharry Medical College, Nashville, Tenn., 1891; aged 53; also a druggist and proprietor of the Burruss Sanatorium, Augusta; died at his home, April 25, from septicemia, due to a wound accidentally received while performing a surgical operation.

Wilford W. White ⊕ Ravenna, Ohio; Western Reserve University, Cleveland, 1881; aged 60; founder and surgeon to the White Hospital, Ravenna, and local surgeon of the Pennsylvania, Baltimore and Ohio and Erie systems; died at his home, May 8, from chronic nephritis.

Joseph Augustus Treat, Orion, Mich.; University of Michigan, Ann Arbor, 1867; aged 77; also a graduate in pharmacy; at one time postmaster of Orion; said to have been the first patentee of a cash register; died at his home, April 28.

Henry Clay Wilber ⊕ Pine Plains, N. Y.; Bellevue Hospital Medical College, 1867; aged 73; president of the Dutchess County Medical Society from 1891 to 1893; health officer of Dutchess County since 1894; died in Brooklyn, May 6.

William Beam, Philadelphia; Jefferson Medical College, 1901; aged 54; for fifteen years chief chemist in the Wellcome Research Laboratory, Gordon Memorial College, Khartoum, Africa; died in Khartoum, April 15, from heart disease.

Arthur Warren Tucker ⊕ Logansport, Ind.; Miami Medical College, Cincinnati, 1893; aged 48; for many years medical examiner for the relief department of the Pennsylvania system; died at his home, May 7, from leukemia.

Will J. Prince, Piqua, Ohio; Eclectic Medical Institute, Cincinnati, 1883; aged 58; once president of the Ohio State Medical Association; died in the Memorial Hospital, Piqua, March 29, after an operation for intestinal obstruction.

John Henry Frederick Schroeder, Minneapolis; University of Minnesota, Minneapolis, 1915; aged 32; assistant in medicine on the faculty of his alma mater; died in the Minneapolis City Hospital, May 2, from diphtheria.

Everett Jones ⊕ Boston; Boston University School of Medicine, 1898; aged 50; a specialist on diseases of the ear, nose and throat; a practitioner of Brookline and Boston; died at his home in Brookline, April 25.

Oscar Edward Hedrick ⊕ **Lieut., M. C., U. S. Army,** Museville, W. Va.; University College of Medicine, Richmond, Va., 1908; aged 33; died at his home, April 18, from pulmonary tuberculosis.

Henry Carroll Holbrook ⊕ Penacook, N. H.; Dartmouth Medical School, Hanover, N. Y., 1885; aged 59; one of the most prominent practitioners of New Hampshire; died at his home, May 3.

Bernard J. Byrne ⊕ Berkeley, Calif.; University of Pennsylvania, Philadelphia, 1871; aged 69; formerly surgeon of the Baltimore and Ohio Railroad at Ellicott City, Md.; died, recently.

Frank Cole Roberts, Fort Madison, Iowa; Louisville (Ky.) Medical College, 1876; aged 63; a member of the Iowa State Medical Association; died at his home, May 4, from nephritis.

Joseph Henry Robinson, Worcester, Mass.; New York University, New York City, 1864; assistant surgeon, U. S. Army, during the Civil War; died at his home, about April 18.

Wilfred Rivers Clayton, Columbia, S. C.; University of Maryland, Baltimore, 1912; aged 30; died in Hopkins, S. C., February 1, from bronchopneumonia following influenza.

Josiah Sylvang Gardner, Kansas City, Mo.; Hospital Medical College of Evansville, Ind., 1885; died in the Research Hospital, Kansas City, May 5, from heart disease.

Frank Hubert Neuhaus ⊕ Houston, Texas; Bellevue Hospital Medical College, 1891; aged 50; a specialist on internal medicine; died in Hot Springs, Ark., May 1.

Elmer E. Barr ⊕ Hyannis, Neb.; State University of Iowa, Iowa City, 1887; aged 55; died suddenly, May 3, while making a professional call in the country.

Melvin Marcellus Lottridge, Pratt, Kan.; Kansas City (Mo.) Medical College, 1893; aged 60; died at his home, April 26, from cerebral hemorrhage.

William Roberts Williams, Plaza, Wash.; Lincoln Memorial University, Knoxville, Tenn., 1893; aged 59; died at his home in Spokane, Wash., May 5.

Rollin Victor Crittenden, Fredonia, N. Y.; University of Buffalo, N. Y., 1895; health officer of Fredonia; died in a hospital in Buffalo, April 30.

Ewald H. Frielingsdorf ⊕ St. Louis; Beaumont Hospital Medical College, St. Louis, 1889; aged 54; died in Josephine Hospital, St. Louis, May 11.

Nelson C. Scudder, Rome, N. Y.; Hahnemann Medical College, Philadelphia, 1879; aged 55; died, March 3, as the result of an automobile accident.

Hiram Tenney Hardy ⊕ Kaneville, Ill.; Dartmouth Medical School, Hanover, N. H., 1867; aged 81; died at his home, May 7, from erysipelas.

J. Rush Philson, Racine, Ohio; Starling Medical College, Columbus, Ohio, 1877; aged 64; died at his home, April 27, from angina pectoris.

Charles H. Winton, Kalamazoo, Mich. (license, Michigan, 1903); aged 75; died in his office in Kalamazoo, March 4, from heart disease.

Mary A. Sperry ⊕ San Francisco; Woman's Medical College of Pennsylvania, Philadelphia, 1890; aged 55; died at her home, May 7.

David Wiley, Salem, N. J.; University of Pennsylvania, Philadelphia, 1870; aged 71; died at his home, April 30, from heart disease.

Robert Edward Miller ⊕ Chicago; Rush Medical College, 1880; aged 72; died at his home, May 2, from *angina pectoris.*

Irving Clendenen, Maywood, Ill.; Bennett Medical College, Chicago, 1876; aged 72; died at his home, May 6.

Paul Revere Hunn, Hartford, Conn. (license, Connecticut, 1893); aged 72; died at his home, *about April 18.*

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

SOME QUESTIONS ANSWERED

Each year the Propaganda department of The Journal receives and answers between four and five thousand letters of inquiry. A large proportion of these letters deal with subjects that have already been discussed in The Journal, and have been reprinted in pamphlet form for easy and inexpensive distribution. Because it does not seem good journalism to reprint, repeatedly, matters that have already been dealt with in The Journal practically all of these inquiries are answered by mail direct. This system, however, ignores the fact that The Journal has many thousands of new readers each year. It also fails to take into account the further fact that the original article on any subject is only read by a certain proportion of those who are The Journal's subscribers at the time it appears. It is desirable, then, occasionally to summarize some of the facts that have already been published regarding certain products or devices not so much for the purpose of restating the specific facts, as for reminding our readers of the large amount of information on the nostrum evil and quackery that is available in the various educational publications issued by the Propaganda department of The Journal. This is the excuse, if excuse be needed, for briefly reprinting a few of the many inquiries that have come in the recent mail:

Kline's Nerve Remedy.—Dr. L. G. Taylor of Hudson, N. Y., writes: "Will you kindly give me information about 'Dr. Kline's Epilepsy Remedy,' Redbank, N. J.?"

Answer: This nostrum was one of several "epilepsy cures" that, about four years ago, were analyzed by the A. M. A. Chemical Laboratory, investigated by the Propaganda department, and described in a series of articles that gave the essential facts regarding the group. The Kline nostrum, one of the usual bromid mixtures, was found to be practically identical with a similar product sold as "Waterman's Tonic Restorative." The matter has been reprinted in full in the pamphlet, "Epilepsy Cures."

Case's Rheumatic Specific.—A member of the editorial staff of one of the leading Boston papers writes, in part: "I am informed that The Journal has published an article about the rheumatism remedy sold by Jesse A. Case of Brockton. I should like to see the article."

Answer: Case's Rheumatic Specific was investigated by the Propaganda department and the product analyzed by the A. M. A. Chemical Laboratory in 1913, an article appearing in The Journal, Jan. 31, 1914. The nostrum was found to have essentially the following composition: Sodium salicylate, 22.4 per cent.; Magnesium oxid, 5.3 per cent.; Licorice root, 72.3 per cent. The article is reprinted in the pamphlet, "Miscellaneous Nostrums."

Diabetol.—An Iowa layman, who does not wish to have his name given, writes: "I have received circulars and letters from the Ames Chemical Co. of Binghamton, N. Y., regarding a preparation they call 'Diabetol,' which they claim is a cure for diabetes. If you have any information as to this claimed remedy, please advise me in confidence whether you consider there is any merit in it or not."

Answer: "Diabetol," which comes in the form of an herb, was investigated by the Propaganda department in 1910. The material was submitted to Professor Millspaugh, Curator of the Department of Botany of the Field Museum, Chicago, and the result of his investigations appeared in the article that was published in The Journal, July 9, 1910. The herb was found to be from a shrub—*Stenolobium stans* (L.)—that grows more or less plentifully from Arizona south through Mexico and Central America. The herb has more or less local reputation as a diuretic. A full report on "Diabetol" has been reprinted in the pamphlet "Nostrums for Kidney Diseases and Diabetes."

Varnesis.—Mrs. Williams (Pennsylvania) writes: "Can you tell me just how much of a fake 'Varnesis' is? I understand you publish such information. If it costs to get this, tell me how much and I will gladly forward the amount. This is supposed to be a rheumatic remedy."

Answer: A brief item on "Varnesis," reporting the findings of the state chemists of Connecticut, is published in the pamphlet "Miscellaneous Nostrums," a complimentary copy of which was sent to Mrs. Williams. At the time of the Connecticut report, Varnesis contained 18 per cent. alcohol, and less than 1 per cent. of vegetable extractives, chiefly derived from laxative drugs and capsicum. Later the alcohol percentage was reduced to 15. Even at that percentage, a person taking it according to the directions, would consume the alcohol equivalent of one-half pint of undiluted whisky every four and one-half days.

Way Ear Drum and Wilson Ear Drum.—Mrs. Neergaard (Michigan) writes: "Will you kindly give me what information you can about George P. Way, Detroit, also the Wilson Ear Drum Co. of Louisville, and their appliances?"

Answer: The George P. Way Ear Drum and the Wilson Ear Drum were both discussed in The Journal, Nov. 1, 1913, and the matter has been reprinted in full in the pamphlet, "Deafness Cures."

Viavi.—Dr. A. R. Rozar, Macon, Ga., writes: "Please give me what information you can on a 'patent medicine' treatment called 'Viavi.' I understand that it is dispensed by agents and not by druggists."

Answer: The "Viavi" scheme emanates from San Francisco, and was very fully dealt with some years ago by the *California State Journal of Medicine*. This article has been reprinted in full, with illustrations added, and appears now in the pamphlet, "Female Weakness Cures." There are various preparations sold under the generic name "Viavi." The "Viavi Capsules" were analyzed for the *California State Journal* and were reported to contain nothing but extract of hydrastis and cocoa butter.

Fulton's Compounds.—Dr. G. B. Taylor, Cameron, Texas, sends the Propaganda department an advertising circular dealing with these nostrums, and asks: "Give me some opinion of the enclosed circular regarding the medicinal properties of this medicine, used for albuminuria and glycosuria."

Answer: The Fulton nostrums were briefly referred to in The Journal as long ago as Jan. 18, 1913. Three years later (Jan. 29, 1916) The Journal published the results of a much more complete investigation of the products. The whole matter has been reprinted in the pamphlet, "Nostrums for Kidney Diseases and Diabetes," and there has been added thereto the government's charge of fraud against the products as reported in a government bulletin in March, 1917.

Nuxated Iron.—Dr. Ross Hopkins, Independence, Kan., writes: "Recently a patient came to me with a skin eruption, and about the only information I obtained was the fact that she had been taking some tablets of 'Nuxated Iron,' made by the Day Health Laboratories of Detroit, Mich. Can you refer me to any statement in The Journal as to the composition of this remedy?"

Answer: "Nuxated Iron" has been dealt with at various times in The Journal, and practically all of the matter has been reprinted in full in the pamphlet "Miscellaneous Nostrums." The analysis by the A. M. A. Chemical Laboratory indicated that each "Nuxated Iron" tablet contained only 1/25 grain of iron, while the amount of nux vomica was practically negligible. Nuxated Iron has been advertised by an extensive campaign of misrepresentation and exaggeration.

Sanosin (Sartolin).—Dr. G. T. Palmer, president of the Illinois Tuberculosis Association, writes: "I am in receipt of a letter from Mr. ——— of Florida, asking for information in regard to a proprietary preparation known as 'Sanosin,' advertised as 'A Highly Successful Home Treatment.' I am enclosing circular herewith. Will you kindly write Mr. ———, giving him such information as you have?"

Answer: Mr. ——— was written to and a complimentary copy of the pamphlet, "Consumption Cures" was sent to him. This contains a reprint of an article that appeared in The Journal, June 18, 1910, regarding "Sanosin," then being introduced in the American market under the name of "Sartolin." "Sanosin" consists of a mixture of powdered eucalyptus leaves, flowers of sulphur, powdered wood charcoal, and oil of eucalyptus. The instructions to the consumptive are that this mixture should be placed on a slab under which an alcohol lamp is burning. The whole thing is supposed to be operated in a room which is tightly closed, and in which the consumptive is supposed to stay. The "Sartolin" advertising matter, at the time The Journal investigated the nostrum, belittled the open air treatment of consumption.

Town's Epilepsy Treatment.—Dr. Parley Nelson, Rexburg, Idaho, writes: "I have a patient taking 'Town's Epilepsy Treatment,' made by the Town Remedy Co. of Milwaukee. If you have any literature on this fake, kindly send me some."

Answer: Dr. Nelson was sent a complimentary copy of the pamphlet, "Epilepsy Cures," which contains the results of the Propaganda department's investigation and the A. M. A. Chemical Laboratory's analysis of the Town remedy, another of the many bromid mixtures.

CIVILIAN MEDICAL ADMINISTRATION AND THE NEED OF TRAINED LEADERS

To the Editor:—The need of a better organization of medical activities is generally conceded. Opinions vary as to the best type of organization. A straightforward system of state medicine seems to many to promise the greatest good. Others, who fear the benumbing effects of a law-bound, bureaucratic state service, suggest as a substitute a state-supervised scheme of sickness insurance, with medical relief for the insured. The strongest of all arguments for compulsory health insurance is, to my mind, that it would open the door to effective medical organization. Compulsory health insurance would not *necessarily* result in effective medical administration, because trained leadership is lacking. It is my belief that the thorough training of even a small group of virile men in the theory and practice of medical administration would materially enhance medical efficiency in this country, and that the time is ripe for such an undertaking. In this connection, let us glance at some of the features of the present situation.

Reports published by the American Medical Association have shown that only a small proportion of the hospitals have interns, the latest data showing the number to be only 17.4 per cent. It is not surprising, therefore, that the American College of Surgeons is finding that few hospitals keep adequate records of their clinical and laboratory work, and are calling for such records as a necessary condition of efficiency. How this deficiency is to be supplied, in the majority of hospitals which are lacking in interns or other personnel competent to keep such records, has not been suggested.

The medical colleges make more and more difficult the pathway of the medical student, while at the same time the number of hospitals increases; consequently, the relative supply of prospective interns rapidly decreases. Moreover, the colleges are dissatisfied with the clinical instruction that hospitals offer their graduates, and with greater and greater emphasis they demand that hospitals which are permitted to employ medical graduates as interns should be brought under the control of the college faculties, at least so far as the training of interns is concerned; to this demand the hospitals are reluctant to yield.

Epidemiologists call upon the hospitals for more complete and uniform morbidity reports; the hospitals reply that they are too poor to undertake additional clerical labor.

Many physicians believe that dispensaries should cease offering free service to the public; the dispensary managers, however, stoutly maintain that the prevalence of poverty amply justifies the prevailing dispensary system.

Social service workers declare that physicians fail to take into consideration the social backgrounds of disease; according to them, the viewpoint of the physician must be radically changed before treatment can become generally efficient. In actual practice, the viewpoint of the physician changes or shifts very slowly.

When the social service worker asks not only for more thorough treatment but for a more careful inquiry into the causes of disease, he touches elbows with the apostles of preventive medicine, whose program embraces eugenics, prenatal care, infant hygiene, school clinics, physical training, the development of recreational facilities, venereal prophylaxis and treatment, industrial hygiene, periodic physical examination, model housing, diagnostic laboratories, and the enactment and enforcement of countless sanitary regulations in urban and rural communities. The relation of the practicing physician to these activities lacks definition.

In letters to the medical press, physicians demand that the state abstain from medical practice; but these very objectors send specimens to laboratories maintained by state and municipal departments of health and thus virtually appeal to the state to aid them in the diagnosis of their cases.

Looking over the country, one observes the transformation of a world-renowned surgical center into a huge diagnostic clinic where group medicine is practiced with such success that surgeons who visit the clinic to study surgical technic become fired with the idea of group medicine and go home eager to form partnerships for the practice of cooperative medicine. On arriving home they discover that group medicine can only be practiced ideally in an institution, and that those who are in charge of suitable institutions, such as hospitals and dispensaries, are not quite ready to turn them over to medical reformers, however well meaning or respectable.

At a critical period of the country's history the established scheme for the training of qualified nurses breaks down, and the leaders of the nursing profession fail to propose adequate measures of relief. In three states there are presented simultaneously six different plans for the solution of the nursing problem; a deadlock ensues, and the country's need remains unsatisfied.

In a thousand communities already possessing imperfectly developed hospitals—hospitals which are wretchedly poor in laboratory equipment and organization—a thousand new hospitals are launched, destined to be poorer still in the essential means of scientific diagnosis and treatment.

Hospitals for the exclusive practice of specialties are begun in communities where the obvious need is the creation of special departments in existing but imperfectly developed "general" hospitals.

Public, semipublic, and private hospitals spring up side by side; why one and not the other, is a question that is hardly considered.

I need not go on. What has been said is sufficient to indicate the lack of clearly defined principles in the development of the machinery of the country for dealing with disease. The muddle seems almost hopeless, but one need not despair if the medical profession can only be made to realize the need of trained leadership. The first thing necessary is to recognize the existence of a tangible problem in which physicians and the public are jointly interested, namely, the problem of medical administration.

Heretofore nobody has been trained in the study of medical administrative problems. The country has drifted into its present chaotic condition because it has been nobody's business to furnish guidance in matters of medical administration. Busy clinicians have here and there thrown out suggestions or made spasmodic efforts for improvement, but for the most part the business of organizing medicine has been left to nonprofessional outsiders. Curiously enough, the need of special training in public health administration is obtaining ample recognition, though this need is no greater than the need of training in medical organization and administration per se. When a state is moved to investigate the need of sickness insurance, and as a preliminary step undertakes to ascertain whether its citizens are receiving adequate medical care, a commission is appointed which usually consists of members of the legislature who are about as competent to report on the subject of medical efficiency as a committee of chimney sweeps would be to report on a problem in astronomy. I have sometimes agreed and sometimes disagreed with the conclusions of legislative committees that have undertaken the investigation of medical problems, but have never been able to bestow much respect on the evidence adduced by uch committees in support of their contentions.

The country may muddle its way through. If so, it will be at the cost of untold suffering and at the needless expense of countless lives. Think our way through we never shall, f the thinking is left to men whose thought and strength are chiefly absorbed by other tasks. Incomparably the best way to treat the matter is to have the study of medical administration organized and directed under university auspices. Universities which already offer courses leading to the degree of doctor of public health are in a favorable position to direct the training of men in medical administration. The two courses would dovetail admirably.

The objection may be raised that teachers of medical administration are lacking. This is true; and therefore, at the outset, the work of special students in this field would have to be to a great extent self-directed; but the gathering of a number of such students at a single center, the assignment to them of appropriate topics of investigation, and the preparation of a series of related theses on phases of medical administration would soon produce a body of thought and fact about which subsequent investigation and teaching could be readily grouped.

The students permitted to participate in this work should be graduates in medicine. Eventually special prevocational courses could be arranged for medical students who purposed following administrative rather than clinical or research medicine; in the prevocational education of the future medical administrator, emphasis should be placed not so much on chemistry, biology, and physics as on psychology, economics and sociology.

What university will be the first to undertake this necessary and valuable work? What philanthropist or philanthropic foundation will be the first to encourage it?

S. S. Goldwater, M.D., New York.

DR. MORTIMER FRANK (1874-1919)—A MEDICAL HISTORIAN

To the Editor:—The sudden death of Dr. Mortimer Frank of Chicago, of whom an obituary appeared in The Journal April 26, was a shock to those of us in the East who had come to know him especially as a research worker in medical history.

Dr. Frank began the study of medical history in his papers on the charlatan oculists, "John Taylor and Sir William Read" (1905), which were followed by others on the Resurrectionists (1907), "Philip Syng Physick" (1911), "Caricature in Medicine" (1911), "Medicine in English Literature Before the Eighteenth Century" (1912), and "Medical Instruction in the Seventeenth Century" (1915). In 1915, he became secretary of the Chicago Society of Medical History and editor of its *Bulletin*, which he much improved in style and format. In 1916, Dr. Frank was invited to read his paper on the "Discovery of the Secretory Glands" before the Medical History Clubs at the Johns Hopkins and Harvard universities. For the Vesalian quatercentenary (1915), he published, at his own expense, a handsome reprint of Henry Morley's "Anatomy in Long Clothes." Dr. Frank was a connoisseur and collector of medical engravings, fine bindings and rare medical books. His private collections were the admiration of his friends and from these he generously donated to the Surgeon-General's Library anything not in its catalogue. At the June meeting of the American Medical Association in 1918, he gave an exhibit of old medical books from his library, with a descriptive catalogue, which is in print. Before his death, he had prepared a lantern-slide lecture on unique title pages in the older medical literature. Dr. Frank's interest in the subject of medical illustration led him to undertake, in 1916, the translation of Choulant's "History of Anatomical Illustration." This book, published in 1852, is one of the classics of medical literature, a work of unsurpassed thoroughness, a sort of *Gradus ad Parnassum* for those who would essay the difficult heights which Choulant has scaled, for the earlier history of anatomy, from Leonardo to the time of Bichat, is mainly in the manuscript illustrations and the illustrated texts. In our days of distracting and divided interests, no man could hope to know the approaches to anatomy in the older writings who has not mastered at least the essentials of this book. Few of us would have cared or dared to attempt such a translation. Choulant is a work of the highest scientific merit, but, in the original German it is not a readable book. Its author wrote in the time of Hegel, his bent was philosophic, his sentences of the sesquipedalian order, like the "long rollers" in Gibbon or Swinburne, or the prosy periods voiced from the pulpit in the Georgian period. Dr. Frank cleverly overcame the almost insurmountable difficulties of rendition by bisecting the long choulantian sentences or dissecting out their meaning, so that his translation now stands, in clean-cut intelligible English, as something viable and readable for modern students. To the original work, long since out of print, the translator added completed bibliographies and an exhaustive *compte rendu* of accumulated research work since the time of Choulant, a man-sized performance in itself. With new illustrations, this modernized Choulant, now in the hands of publishers, may be, in course of time, a *vade mecum* for the professor of anatomy, the medical librarian and the art school.

Dr. Frank was a sportsman and a gentleman, a thoroughly likeable and loveable man, a very faithful and loyal friend.

To those who knew him well, it will always seem triste and unthinkable that he should have been cut down in his prime, just before the appearance of the book to which he had devoted so much of praiseworthy competence and such ardors of patient research.

F. H. Garrison, M.D., Washington, D. C.

"IDENTITY OF THE POPPY IN FLANDERS FIELDS"

To the Editor:—A correspondent in The Journal, April 26, wondered whether Flanders poppies are of the opium kind. Yesterday in a New Hampshire car I saw a loan appeal illustrated with a Flanders grave on which were red poppies with a black center. On talking about it, I learned that the poppy is commonly regarded as the flower of sleep or of death. I enclose two quotations and a reference to a picture, Beata Beatrix, which is in the museum of the Chicago Art Institute:

> On the grass of the cliff, at the edge of the steep,
> God planted a garden, a garden of sleep;
> 'Neath the blue of the sky, in the green of the corn,
> It is there that the regal red poppies are born.
> In my garden of sleep, where red poppies are spread,
> I wait for the living, alone with the dead.
>
> —*From a song by de Lara.*

> Here are cool mosses deep,
> And through the moss the ivies creep,
> And from the craggy ledge
> The poppy hangs in sleep.
>
> —Tennyson: *The Lotus Eaters.*

The dove bears the poppy, symbol of sleep eternal, the death flower—to Beatrix as the sundial reaches its shadowless hour.—Rossetti: Beata Beatrix.

F. K. Bryant, Chicago.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

THE DIFFERENTIAL STETHOSCOPE

To the Editor:—Please describe the differential stethoscope mentioned in the abstract of Thorne's article published in the London Practitioner, April, 1919. P. W. V., Columbia, Mo.

Answer.—Thorne describes this instrument as follows: "The differential stethoscope consists of the usual binaural ear-pieces and tubing, which are connected with a hollow aluminum chamber, divided transversely by a septum into two compartments, the upper being connected to the ear-pieces by the tubing, the lower having the chest-piece attached to it. The center of the dividing septum is pierced by a conical opening, into which a metal cone can be inserted or withdrawn, closing it completely or varying the size of the opening, and thus allowing more or less of the sounds to reach the examiner's ear. The position of the cone is indicated by a pointer on the upper surface of the chamber, and the figures shown there give the values of the sounds passing through the aperture with the cone in varying positions.

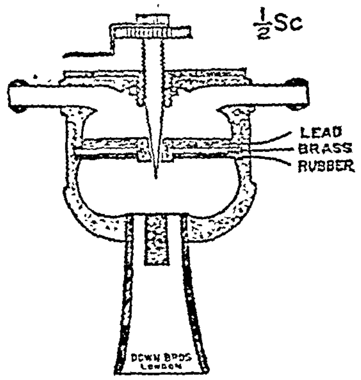

Fig. 1.—Cross section of sound chamber of the stethoscope.

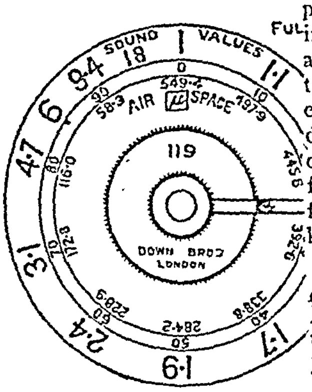

Fig. 2.—Indicator giving sounds.

It has been found by experience that the value of the first sound at the apex in a normal healthy heart is about double that of the second sound at the base. For example, in a healthy heart, if the first sound at the apex registers 3.2, the second sound at the base will be in the region of 1.6; or if the former is 4.7, the latter will be about 2.4. This is considered the normal 100 per cent. ratio. A ratio falling below 50 per cent. normal standard is evidence of myocardial debility. To use the differential stethoscope, apply the chest-piece to the apex of the heart, having previously rotated the pointer one complete revolution from left to right from the closed position so that it stands at 0. Now slowly close it, turning the pointer from right to left until the first sound is just not audible, mark the figure on the dial, perhaps it is 3.2. Now place the chest-piece over the aortic base, and repeat the same procedure, noting the figure at which the second sound is just not audible, say it is 2.4. The figures 3.2 and 2.4 are about 25 per cent. normal. This would indicate a weakness of the myocardium. A normal heart would probably have given a reading of 3.2, 1.6; 4.7, 2.4; or 6, 3.2. That is about 100 per cent. normal standard."

In *The Practitioner* (100:234, March, 1918), O. Peyton gives a very detailed description of this instrument and also publishes some illustrations. He calls attention to the importance of having rubber tubes which are at least two feet long and preferably of not a very thick wall. The object for having these long tubes is to permit of the movement of the chest-piece from one area to another without moving the ear-pieces. The reason why the walls of these tubes should not be too thick is to prevent the conduction of sound along their walls; the sound should be air-borne only.

acter. A subdivision is made of those beverages which contain toxic properties, whether developed naturally in the manufacture or added to the product afterward. The alcoholic beverages, coffee and tea come in this division because of the alcohol or caffein they contain. There would also be included those "soft drinks" to which caffein and (nowadays rarely) cocain have been added. The book, as its title denotes, does not take up for consideration questions of health, hygiene or ethics, although each of these problems is incidentally discussed as occasion seems to demand. The object of the volume is, however, to describe the origin, methods of manufacture, composition and the conditions attending transportation and use of the common beverages. Dr. Wiley's long connection with the Bureau of Chemistry and his uncompromising attitude toward all forms of fraud and misrepresentation give his pronouncements on various problems connected with what may be called the beverage industry of the country, both weight and interest. As its authors says, the book is "not written for the scientific investigator but for the average sober-minded, reasonably well-educated American citizen, who is daily taking a greater and deeper interest in what he eats and drinks." To this class one may fairly assign the rank and file of the medical profession, and the book is one that the average physician will find a valuable addition to his library of semitechnical knowledge.

La Tuberculosis: Conocimientos Utiles Para el que la Padece, Quienes con él Viven y Para Todos los que Deseen Ponerse al Abrigo de la Enfermedad. Distribuido por el State Tuberculosis Sanatorium, Bureau of Correspondence and Information. Carlsbad, Tom Green County, Texas. Rústica. Pp. 35. New York: The National Tuberculosis Association, 1919.

This is a Spanish translation of the pamphlet for popular use previously issued by the National Tuberculosis Association. The prevalence of tuberculosis among the Spanish-speaking population of the Southwest constitutes a serious problem, and the action of the National Tuberculosis Association in making the useful information in this pamphlet available in Spanish is praiseworthy.

Medicolegal

Physician as Witness Getting Percentage of Judgment

(Davis v. Smoot (N. C.), 97 S. E. R. 488)

The Supreme Court of North Carolina affirms a judgment in favor of the plaintiff, administrator of the estate of one A. M. Davis, against the defendant, a physician, for $125, the amount which the defendant had collected of said A. M. Davis for testifying as a witness in a personal injury case against the city in which said A. M. Davis recovered $625. The court says that these issues were submitted to the jury in this action against the physician: (1) Did the defendant knowingly, designedly, wilfully, and maliciously and unlawfully charge A. M. Davis 20 per cent. of the amount recovered by A. M. Davis from the city as alleged in the complaint? Answer: Yes. (2) What amount, if anything, is the defendant indebted to the plaintiff? Answer: $125. The defense was rested on the ground that the agreement was void as public policy, and hence that, the money having been

Answer.—The extremities are rarely involved in chickenpox, whereas they are usually involved more or less extensively in smallpox. The character of the eruption is quite distinctive. In smallpox it is hard, "shotty," indurated. sharply circumscribed, umbilicated, whereas the opposite is true of the chickenpox lesion. This will help to remove any doubt that might exist as to the nature of the disease, if any eruption is present on the palms of the hands or soles of the feet.

Social Questions and Infant Mortality.—To correct the evils which underlie a high infant mortality rate, we must face all the great social questions of our age.—*Public Health News*, New Jersey.

suggestions or made spasmodic efforts for improvement, but for the most part the business of organizing medicine has been left to nonprofessional outsiders. Curiously enough, the need of special training in public health administration is obtaining ample recognition, though this need is no greater than the need of training in medical organization and administration per se. When a state is moved to investigate the need of sickness insurance, and as a preliminary step undertakes to ascertain whether its citizens are receiving adequate medical care, a commission is appointed which usually consists of members of the legislature who are about as competent to report on the subject of medical efficiency as a committee of chimney sweeps would be to report on a problem in astronomy. I have sometimes agreed and sometimes disagreed with the conclusions of legislative committees that have undertaken the investigation of medical problems, but have never been able to bestow much respect on the evidence adduced by such committees in support of their contentions.

The country may muddle its way through. If so, it will be at the cost of untold suffering and at the needless expense of countless lives. Think our way through we never shall, if the thinking is left to men whose thought and strength are chiefly absorbed by other tasks. Incomparably the best way to treat the matter is to have the study of medical administration organized and directed under university auspices. Universities which already offer courses leading to the degree of doctor of public health are in a favorable position to direct the training of men in medical administration. The two courses would dovetail admirably.

The objection may be raised that teachers of medical administration are lacking. This is true; and therefore, at the outset, the work of special students in this field would have to be to a great extent self-directed; but the gathering of a number of such students at a single center, the assignment to them of appropriate topics of investigation, and the preparation of a series of related theses on phases of medical administration would soon produce a body of thought and fact about which subsequent investigation and teaching could be readily grouped.

The students permitted to participate in this work should be graduates in medicine. Eventually special prevocational courses could be arranged for medical students who purposed following administrative rather than clinical or research medicine; in the prevocational education of the future medical administrator, emphasis should be placed not so much on chemistry, biology, and physics as on psychology, economics and sociology.

What university will be the first to undertake this necessary and valuable work? What philanthropist or philanthropic foundation will be the first to encourage it?

S. S. Goldwater, M.D., New York.

DR. MORTIMER FRANK (1874-1919)—A MEDICAL HISTORIAN

To the Editor:—The sudden death of Dr. Mortimer Frank of Chicago, of whom an obituary appeared in The Journal April 26, was a shock to those of us in the East who had come to know him especially as a research worker in medical history.

What Constitutes a "College"

Since all medical schools are now requiring for admission "two years of college work" they will be interested in the definition of a college which was adopted by the National Conference Committee on Standards of Colleges and Secondary Schools at its meeting held in New York City, March 24, 1919. This definition is as follows:

1. A requirement for admission of fifteen (15) units of secondary work, not more than two (2) units of condition being allowed, all special students under 21 years of age being required, except in rare and unusual circumstances, to meet all the requirements for admission, preparatory courses, if any, being distinct in faculty, students, and discipline.
2. A program of studies having a reasonable relation to the resources of the institution.
3. A liberal curriculum, with advanced work in several fields, and a reasonable margin for free election, the curriculum to be of such a character as to qualify for admission to a graduate school of recognized standing.
4. A college year of thirty-two (32) weeks of actual instruction.
5. Eight (8) departments, each having at least one full-time teacher of professorial rank.
6. A staff, two-thirds of which are of professorial rank, having had at least two (2) years of study in a graduate school of recognized standing, receiving salaries of two thousand dollars ($2,000) a year or more, and teaching not more than sixteen (16) hours a week.
7. A productive endowment, beyond all indebtedness, of three hundred thousand dollars ($300,000).
8. An annual income for current expenses of forty thousand dollars ($40,000) a year, at least three-fifths of which is expended for instruction.
9. An expenditure of one thousand dollars ($1,000) a year for laboratory equipment and apparatus, and of one thousand dollars ($1,000) a year for books and periodicals.
10. An annual or biennial published report of assets, income, expenditure, faculty, curricula, and student body.

New York January Examination

Mr. George M. Wiley, director, Examinations and Inspections Division, reports the written examination held at Albany, Buffalo, New York and Syracuse, Jan. 28-31, 1919. The examination covered 8 subjects and included 80 questions. An average of 75 per cent. was required to pass. Of the 93 candidates examined, 60 passed and 33 failed. The following colleges were represented:

College	Year Grad.	No. Licensed
PASSED	(1916)	1
Leland Stanford Junior University	(1918)	1
Yale University	(1898)	1
Illinois Medical College	(1916)	1
University of Maryland	(1917)	1

Book Notices

ESSENTIALS OF SURGERY: A TEXTBOOK OF SURGERY FOR STUDENT AND GRADUATE NURSES AND FOR THOSE INTERESTED IN THE CARE OF THE SICK. By Archibald Leete McDonald, M.D., the Johns Hopkins University. Cloth. Price, $2 net. Pp. 265, with 46 illustrations. Philadelphia. J. B. Lippincott Company, 1919.

For the past five years it has been the fortune of the reviewer to be called on to give the course in junior surgery at a large nurses' training school. He has often been at a loss to recommend to his students sources from which they might supplement the lectures. The average textbook on surgical subjects is written for the medical student or graduate in medicine, and hence presupposes a thorough medical training on the part of the reader; such books, therefore, are confusing to the student nurse, and she often gains an erroneous impression of a subject, even if she may be persuaded to struggle through the appropriate chapters of the recognized authorities.

"Essentials of Surgery" appears to have been written with a clear understanding of the needs and of the capacity of those for whom it is intended. In the preface, the author states:

> These notes are prepared for the use of senior nurses in connection with a course on the principles of surgery, in the belief that the nurse can more intelligently assist in the care of her patient if she has a reasonable conception of the conditions present and of the indications to be met in the treatment. . . . The course covers the general principles of surgical diseases and the pathologic changes which result.

The subject-matter is presented in a concise, logical fashion, with due regard to scientific exactness, and yet without sacrificing simplicity of statement or becoming a mere dry recital of facts. Considering its size, the work is a veritable mine of information, wonderfully condensed, and even the medical student preparing for examination would find here a useful guide.

At the end of each chapter is a table of demonstrations, presumably for the use of the lecturer in amplifying the text. They appear to be worth while.

Thirty pages are devoted to a glossary of words in everyday use in surgery, but which, to the uninitiated, may well be most confusing. While all these terms appear in every medical dictionary, there still seems to be justification for their inclusion in a glossary in this book, since no one can understandingly read, or listen to discussions, concerning a science with the terminology of which he is unfamiliar; moreover, by simply defining terms, one can many times impart information in a few words which might otherwise require pages of explanation.

While heartily approving of the book as a whole, it may not be amiss to call attention to a somewhat careless use of English which occasionally appears. For instance, on page 4, we read: "An antiseptic or germicide is an agent which destroys bacteria, including the following: *A*, direct heat; *B*, steam; *C*, chemicals." While, of course, no one would misunderstand the author's meaning, yet he definitely appears to say that direct heat, steam and chemicals are bacteria subject to destruction by an antiseptic or germicide. Fortunately, lapses of this kind are not common enough to detract from the usefulness of the book, and they are mentioned chiefly to magnify the necessity for careful proof-reading and attention to grammatical constructions in the preparation of books of reference.

BEVERAGES AND THEIR ADULTERATION: ORIGIN, COMPOSITION, MANUFACTURE, NATURAL, ARTIFICIAL, FERMENTED, DISTILLED, ALKALOIDAL AND FRUIT JUICES. By Harvey W. Wiley, M.D. Cloth. Price, $3.50 net. Pp. 421, with 42 illustrations. Philadelphia: P. Blakiston's Son & Co., 1919.

This, a companion volume to the author's earlier work, "Foods and Their Adulterations," comes at an especially appropriate time when the greatest experiment in changing the beverage-habits of a nation is about to be initiated. More than half of the book is devoted to a consideration of beverages of the alcoholic type. Beverages are conveniently divided by Wiley into two main classes, (1) those which, in addition to having condimental properties, have also food value, and (2) those which are purely condimental in character. A subdivision is made of those beverages which contain toxic properties, whether developed naturally in the manufacture of added to the product afterward. The alcoholic beverages, coffee and tea come in this division because of the alcohol or caffein they contain. There would also be included those "soft drinks" to which caffein and (nowadays rarely) cocain have been added. The book, as its title denotes, does not take up for consideration questions of health, hygiene or ethics, although each of these problems is incidentally discussed as occasion seems to demand. The object of the volume is, however, to describe the origin, methods of manufacture, composition and the conditions attending transportation and use of the common beverages. Dr. Wiley's long connection with the Bureau of Chemistry and his uncompromising attitude toward all forms of fraud and misrepresentation give his pronouncements on various problems connected with what may be called the beverage industry of the country, both weight and interest. As its authors says, the book is "not written for the scientific investigator but for the average sober-minded, reasonably well-educated American citizen, who is daily taking a greater and deeper interest in what he eats and drinks." To this class one may fairly assign the rank and file of the medical profession, and the book is one that the average physician will find a valuable addition to his library of semitechnical knowledge.

LA TUBERCULOSIS: CONOCIMIENTOS UTILES PARA EL QUE LA PADECE, QUIENES CON ÉL VIVEN Y PARA TODOS LOS QUE DESEEN PONERSE AL ABRIGO DE LA ENFERMEDAD. Distribuído por el State Tuberculosis Sanatorium, *Bureau of Correspondence and Information.* Carlsbad, *Tom Green County, Texas.* Rústica. Pp. 35. New York: The National Tuberculosis Association, 1919.

This is a Spanish translation of the pamphlet for popular use previously issued by the National Tuberculosis Association. The prevalence of tuberculosis among the Spanish-speaking population of the Southwest constitutes a serious problem, and the action of the National Tuberculosis Association in making the useful information in this pamphlet available in Spanish is praiseworthy.

Medicolegal

Physician as Witness Getting Percentage of Judgment

(Davis v. Smoot (N. C.), 97 S. E. R. 488)

The Supreme Court of North Carolina affirms a judgment in favor of the plaintiff, administrator of the estate of one A. M. Davis, against the defendant, a physician, for $125, the amount which the defendant had collected of said A. M. Davis for testifying as a witness in a personal injury case against the city in which said A. M. Davis recovered $625. The court says that these issues were submitted to the jury in this action against the physician: (1) Did the defendant knowingly, designedly, wilfully, and maliciously and unlawfully charge A. M. Davis 20 per cent. of the amount recovered by A. M. Davis from the city as alleged in the complaint? Answer: Yes. (2) What amount, if anything, is the defendant indebted to the plaintiff? Answer: $125. The defense was rested on the ground that the agreement was void as against public policy, and hence that, the money having been paid, the plaintiff administrator could not recover it back. It is public policy that such a contract as this cannot be enforced, but it is also public policy that such a transaction as this cannot be allowed to stand simply because the defendant was able to enforce payment of the illegal exaction. Besides, there was in this case evidence that the defendant physician gave said A. M. Davis morphin and other medicine; that the latter's mind while the defendant was visiting him and giving him morphin was in a very unsatisfactory condition; and that the defendant, who "had made a very good witness," collected the $125 with great promptness after A. M. Davis had received it.

The ground of the recovery sought by the plaintiff administrator was, not that the defendant swore falsely in favor of A. M. Davis, but that he made representations that his

Legitimate Use of Narcotics in War Time.—The legitimate use of narcotics in the army in war time is roughly divided by Bishop into two broad divisions: First, the necessary administration of morphin to those who are addicted for the control of emergency or other indication—with which every competent physician or surgeon is familiar. To use morphin in such cases is not only legitimate, but failure to use it, Bishop says, would be inhuman and barbarous and result in the loss of hundreds of thousands of lives and the making of wrecks of hundreds of thousands of others. Second, the administration of opiates to those unfortunates, who either through their own ignorance or carelessness or through unavoidably prolonged legitimate or necessary medication have developed in their body the condition of opiate addiction disease—until such time as they can either be furloughed or discharged from active service for the radical arrest by competent medical care of their addiction disease mechanism.

Mosquito Eradication in Southeastern Pennsylvania.—The work done by Royer and Emerson at Hog Island and nearby places is given in considerable detail in this paper. It shows what can be done in malarial districts, how to organize and how to accomplish results. These results show that a comprehensive cooperative project embracing private corporations, municipal and state agencies is practical, providing the work is performed in accordance with a comprehensive plan previously approved by the various interests concerned, and general direction of the project placed in some unbiased central organization, so formed either by law or mutual consent that its jurisdiction covers the entire territory. This would seem to indicate that general supervision should be placed in some permanent, central authority having uniform powers and responsibilities, such as the state department of health. Benefits of mosquito eradication work are far-reaching, and include not only increase in value of properties within the immediate district but also general real estate values within a wide area. The same applies to the benefits to public health. The work carried on under the conditions set forth in this paper has had beneficial results as is proved by the fact that complaints from residents and workers in the district were almost unknown this past summer and that preparations are now being made for the cultivation of large areas of land which for years have remained idle, covered with a luxuriant growth of weeds and water vegetation.

Children's Year Campaign.—The recorded results of the weighing and measuring test give the largest mass of material ever gathered on the measuremens of young children. In a mid-western city of about 70,000 population, largely foreign, the immediate results of cooperation in Children's Year have been three child welfare nurses; a milk inspector; publication of milk reports with bacterial count, sediment, etc.; an agreement between dairymen and farmers by which all milk sold in the town will be produced within a radius of 10 miles and properly taken care of until it reaches the city; a summer hospital for babies; a milk depot; an organization of ten volunteer nurses to look up babies in the congested foreign district and to instruct the mothers how to care for their children; the cleaning up of streets and alleys of the congested districts, and four infant welfare stations, to be established in order to carry on the work permanently. One of the large but less populous states reports 41,000 weighed and measured with 32,000 complete physical examinations by physicians in only one half its counties, with many counties still at work.

As the result of the tabulations of remediable defects from this one campaign, seventeen permanent health centers have been established, several counties have each a public health nurse, and lately the state has established a Division of Child Hygiene under the state board of health. In another more populous state, most competently organized, every county in the state but four (102 in all) has had child welfare chairmen, with 360,000 children weighed and measured. The states have varied widely in their child welfare campaign undertakings, but there is not a state in the Union which has not had some part in the Children's Year weighing and measuring program. Publicity by means of posters, dodgers, stickers, slides, and motion picture films of Children's Year has been widespread throughout the country largely depending for success on the activity and ingenuity of local chairmen. An interesting innovation in propaganda has developed in the portable welfare center and dental clinic. Michigan has a "Children's Year Special," an interurban car which was sent out on a six weeks' trip with a trained nurse in charge. Local committees and local physicians cooperate in each town. The expense of the car is donated by the railroad company.

Health Officer and Enforcement of the Law.—The enactment of comprehensive state legislation on the following lines is advocated by Craster: (1) A state health service similar to the U. S. Public Health Service. (2) The payment by the state of part of the health officers' salaries. (3) A state poor relief or old age pension plan. (4) State insurance against tuberculosis disability. (5) State control of tuberculosis sanatoria with the establishment of state preventoria for children. (6) A milk ordinance for the state. (7) A plumbing code for the state. (8) State control of animals slaughtered for food on farms.

Central Giant-Cell Sarcoma of Lower End of Ulna.—A recent observation made by Bloodgood of this type of tumor involving the lower end of the ulna in which the bony shell was completely destroyed led him to reinvestigate forty-seven cases of giant-cell tumor with especial reference to destruction of the bony shell or its perforation with infiltration of the surrounding soft parts. This study demonstrated that the complete destruction of the bony shell or its perforation at one or more spots with infiltration of the giant-cell tumor tissue has not been associated with any difference in malignancy. There have been no deaths from metastasis in these forty-seven cases. In fact, in these forty-seven cases there is not a single example of death from any cause which could be attributed to the tumor. In many instances the local growth of the sarcoma which has caused death by metastasis, had been just as circumscribed and, in some instances, more circumscribed, than the local growth of the gant-cell tumor. The size of the local growth which produced death by metastasis is not necessarily large. It is, therefore, of the utmost importance, especially in relation to bone tumors, to be able to recognize the giant-cell tumor, because when it is recognized a cure should be accomplished with little or no mutilation beyond that due to the destruction of tissue by the tumor itself. It is important to recognize the central giant-cell tumor at the exploratory incision; and when it is recognized and its benignity accepted, Bloodgood is convinced that more cases will be subjected to curetting and resection will only be done when made necessary by the complete absence of the bony shell, or when resection will leave the limb with equally good function.

Osteogenesis.—Study of two specimens recovered at necropsy, together with extensive animal experimentation, has convinced Mayer that the fully developed bone cell has no power of division and that bone growth results from the activity of cells lying between the bone and the outer layer of the periosteum. Experiments prove that when these cells are removed the bone itself is not capable of reproducing them, but that the periosteum has that power. In transplantations, the bone graft acts partly as a scaffolding for the ingrowth of osteogenetic cells, but it contributes also to its own life, first by the persistence of some of its bone cells, second by the activity of the transplanted periosteum. The graft grows in its new situation and becomes modified in its form according to the changed mechanical conditions (Wolff's law).

Effacement of Cavities in Treatment of Fractures.—The authors emphasize the importance of obliteratng all so-called "dead" spaces which may form after improper treatment of fractures. They remove sufficient bone so that the soft tissues fill in any cavity formed. Thus there is little danger of infection occurring later. They illustrate by citing cases. The Hemequin apparatus is always used by them in these cases and with good results.

Synthetic Transplantation of Tissues to Form New Finger.—In cases in which severe laceration of the hand by high explosive shells and shrapnel necessitated the immediate amputation of the four fingers with all, or the greater part, of the adjoining metacarpal bone, Albee suggests constructing an entirely new digit by means of synthetic transplantation of tissues. The procedure was carried out successfully in two cases. This "finger" has provided in each instance the necessary opposition to the thumb, transforming the hitherto helpless stumps into useful members. The operation was done in two stages. First, a rectangular flap of skin and subcutaneous tissue was turned up from the chest wall and sutured into the form of a *finger*. *Its end* was approximated to the edges of an incision in the stump of the hand made over and down to the distal surface of the os magnum, by the Italian plastic method. A pedicle was left attached to the chest wall to supply nourishment to the newly implanted parts until circulation with the hand should be established thoroughly. In the second step, the boneless finger, cut loose from the chest wall, was first *tunneled* by means of a scalpel and a wedge-shaped mortise was made in the distal-radial surface of the os magnum with an osteotome. Into this mortise a wedge-ended tibial graft, 3 inches long and about ⅜ inch wide, was firmly driven. A sliver graft was affixed along the ulnar side of graft No. 1, for purposes of "bone-seed," or increased osteogenesis. The skin was closed with interrupted silk sutures. The result was excellent. The patient was able to use this new finger for holding a pencil, knife, fork, pulling on his shoes, etc.

Experimental Cranioplasty.—Wegeforth is of the opinion that the logical material to use in cranioplasty consists of plates of cranial bone, for (1) the requirements of protection for the brain and restoration of the shape of the head can be accomplished immediately; (2) the formation of cartilage, with possible resulting exostoses, is avoided. Animal experimentation (on cats) indicates that either living or dead grafts may be used *effectively in the head*. In man, living grafts are recommended, but if they are not available, plates of sterilized cranial bone are preferred to any other tissue.

Hypertonic Gum Acacia and Glucose in Treatment of Secondary Traumatic Shock.—On the basis of animal experiments made by Erlanger and his collaborators and others on the mechanism and treatment of shock, they conclude that slowing of the circulation in a considerable part of the body, or in the whole body, is commonly, if not always, the factor that leads to the development of experimental shock. It is believed that as a result of the slowing of the blood stream the corpuscles clump in the venules and capillaries which then become choked with solid masses of corpuscles and dilate. The blood flow is thus curtailed still further, in fact to the point of interfering seriously with the processes of tissue respiration and nutrition. The effective blood volume is reduced, not alone by the dilatation, but also by transudation of plasma. The organism strives to combat this real and effective reduction in blood volume by the usual mechanism of pouring tissue fluids into the blood stream. Largely, if not exclusively, as a result of the deficient general circulation resulting from the reduction in effective blood volume, the medullary centers, including the vasomotor centers, and the heart, eventually may show some signs of functional insufficiency.

The administration of a combination of hypertonic gum acacia and hypertonic glucose under these circumstances acts beneficially, in several ways: (a) By drawing fluids from the tissues into the blood stream, thus assisting the normal mechanism in restoring the blood volume. (b) By maintaining this increased volume through some property of the gum acacia. (c) By dilating the arterioles through some specific action of the hypertonic crystalloid. (d) By increasing the energy of the heart beat in the same way, and also through direct action of the glucose on the muscle. (e) By augmenting metabolism through the increase in the supply of glucose to the organism between the limits of basal metabolism and self regulation. There is no need of providing salts with this injection, because the solution is given in relatively small quantity (5 c.c. per kilogram of body weight) and very slowly. The withdrawal of water from the tissues seems to do no harm, probably because of the large supply available, and the loss that does occur can and should be made good by the administration of water by mouth, by rectum, and hypodermically. The results obtained through the use of the solution in the treatment of shock-like states in man (twelve cases) and after hemorrhage, show conclusively that the solution is innocuous and they are strongly suggestive, to say the feast, of beneficial action.

Exposure in Gallbladder Surgery.—Masson prefers to remove the gallbladder from below upward. In order to do this well, good exposure of the gallbladder is needed. The method used by Masson is said to help in the more difficult cases to visualize the neck of the gallbladder, the cystic duct and artery, and also their relations to the common duct and the duodenum. The abdominal incision extends from the midline at the tip of the ensiform to a point about 2 inches external to the umbilicus. If it is necessary to remove the appendix the incision may be extended downward, especially if there is an excessive amount of subcutaneous tissue. The stomach, large bowel, omentum and small intestine, are separated from the field of operation by three or four abdominal sponges, held in place by the left hand of an assistant.

In almost all such cases this exposure is all that is needed, even when the right lobe of the liver cannot be rotated. In the exceptional case, however, additional exposure is obtained by inserting a pack (4 inches by 3 feet) between the posterior superior surface of the right lobe of the liver and the diaphragm. In this manner the liver is made to descend slightly, the concave visceral surface is flattened somewhat, and the hilum of the liver is made more accessible. The insertion of this pack is an easy matter and if carefully placed it can in no way injure either the liver or the diaphragm. With an ordinary abdominal retractor the second assistant retracts the right costal margin upward and outward, while with a long shoe horn retractor the first

the dates of final healing differ by the same amount as the lengths of the respective quiescent periods. The diet, therefore, is a factor in determining the date of the beginning of Period II, the period of granulous contraction. The formation of the epithelium, Period III, starts on the same day, irrespective of the diet and the size of the wound. Diet has no effect on either the date of beginning of Period III or the course of epidermization. The difference between the two curves gives the area of the epithelium. After the wound is healed the scar continues to contract until pigmentation sets in. During this latter process it enlarges and reaches a stationary state after pigmentation is complete.

Relation of Spontaneous Nephritis to Experimental Lesions.—An attempt was made by Bloomfield to produce chronic nephritis in rabbits by intravenous injections of streptococci, following a direct injection into the renal artery. Failure to produce chronic glomerular lesions was thought to be due to the means used by the kidney to dispose of injected organisms, which resulted in complete healing if the glomerulus survived the acute injury. Chronic focal lesions were found in many animals. Control examinations of the kidney at the beginning of the experiment, and comparison of differently treated right and left kidneys suggest that all these lesions represented the "spontaneous nephritis of rabbits."

Effect of Different Bloods on Growth of Influenza Bacillus.—In making routine throat cultures, Rivers noticed that on certain days the colonies of *B. influenzae* were large and easy to isolate, whereas on other days they were very small and often overlooked. The results from day to day differed so much that an explanation was sought. It was found that on the days when the colonies were large either cat or rabbit blood had been used and human blood when they were small or overlooked.

Clinical Pharmacology of Digitalis.—Wedd's communication is compiled from data on unselected cardiac and cardiorenal hospital patients to whom digitalis was given, including twenty-nine in whose cases electrocardiographic records were taken every twenty-four hours, or more frequently, during the period of administration of a standardized preparation of the drug. It was soon apparent that successive tinctures supplied to the hospital wards showed marked variation in their efficiency. Two biologically standardized tinctures of approximately theoretical strength were studied and it appeared that the inefficiency of one was due to failure of prompt absorption from the alimentary canal, as was indicated by the larger amount necessary to produce a change in the T wave, the earliest demonstrable digitalis effect. Daily doses averaging 10 c.c. were given and continued until alimentary disturbances or abnormalities in the cardiac mechanism appeared. In no case was there any ill effect attributable to digitalis and there were no evidences of the so-called cumulative action. The toxic dosage showed marked individual variation, from 20 to 100 c.c. The earliest signs of toxicity were slight nausea and premature beats. It is believed to be a perfectly safe procedure and one which will promptly bring about the expected benefits of digitalis to begin with an initial dose of 5 c.c. of tincture and to continue with 8 or 10 c.c. daily until signs of toxicity appear or until clinical improvement warrants discontinuing the drug. In the series studied were cases with all possible valvular defects, all grades of decompensation, renal lesions of varying degrees of severity, systolic blood pressures ranging from 90 to 230 mm. and almost all of the recognized types of myocardial involvement, including cases of intraventricular block and complete dissociation, and there was not found any clinical entity which might be said to constitute a contraindication to the use of digitalis.

*Diphtheroid Infection of Wounds:—Frequency of Diphtheroid Bacilli in Urethritis and Prostatitis. R. M. Janes and N. O. Thomas, Buxton, Eng.—p. 434.

Diphtheroid Bacilli in Urethritis and Prostatitis.—One hundred and twenty-nine wounds were examined bacteriologically (swabs) by Janes and Thomas. Eighty-two, or 63.5 per cent., showed diphtheroid organisms. Of these, thirty were isolated in pure culture at intervals during a period of four months. Three of these proved to be true Klebs-Loeffler bacilli and twenty-seven were wound diphtheroids, that is, 10 per cent. of the isolated organisms were *B. diphtheriae*. Assuming that this is a fair proportion, then 6.4 per cent. of the wounds were infected with *B. diphtheriae*. Clinically, it is impossible to diagnose between diphtheroid and true diphtherial infection of wounds. A membrane does not necessarily indicate the presence of *B. diphtheriae* wounds. It is not possible to distinguish between diphtheria bacilli and wound diphtheroids by morphologic characters. Only by sugar reactions obtained from pure cultures can diphtheroid organisms be distinguished from true Klebs-Loeffler and only after positive animal inoculation is it advisable to diagnose diphtheria in wounds. Flavine appears to have given better results than any other form of local treatment used. The authors believe that it is advisable to administer diphtheria antitoxin in cases of diphtheria in wounds. The importance of giving a sensitizing dose in cases of war wounds due to their having received previous injections of serum is emphasized, on the basis that if this rule is not followed severe anaphylactic reactions will occur in some cases.

Rotation of Sacro-Iliac Joint.—Swaim reports a series of cases in support of the theory that rotation of the sacro-iliac joint may occur.

Syphilis of Bones and Joints.—The differential points in the diagnosis of syphilis of bone and joint conditions are discussed by Wallace. He says that in all suspected cases of syphilis of bones and joints, it is essential to go into the family and personal history of the patient in minute detail, bringing out a complete history of the parents as to chronic rheumatism, various eye troubles, chronic bone suppurations, miscarriages, sterility, etc., as well as the definite history of the primary infection in either parent. In the personal history of the patient, in congenital syphilis, one should look for such symptoms as rhinitis, lesions of the skin and mucous membranes, iritis, suppurating lesions of hands or feet and malnutrition. In a negative history one must not overlook the fact that in any suspected case a Wassermann test should be made. In about 15 per cent. of Wallace's cases the condition followed a definite history of trauma. In 50 per cent. of the cases of acquired syphilis osteocopic pain was present in a very severe form; in 19 per cent. of the congenital cases there was no osteocopic pain present, although there was extensive involvement of the bone. Pain was present in every case except one, but it was insignificant in proportion to the pathology present. Swelling was present in 50 per cent. of cases. In 70 per cent. of the cases tenderness was elicited, and of the ten cases not showing tenderness, five were cases of spinal syphilis or Charcot spine. Redness and local increase of temperature were present in only ten cases. Fluctuation was comparatively a rare sign, being present in only 9 per cent. of cases. In twenty-seven cases in which there were joint symptoms, 50 per cent. had limitation of motion. One case showed a characteristic kyphosis with no other local physical signs, although the roentgenogram showed destruction of two dorsal vertebrae. In another case with no deformity, showing no local physical signs, evidence of bone destruction with new deposits of bone was seen in the roentgenogram. In a series of thirty-eight cases, a positive Wassermann was obtained in twenty-four; two doubtful, eight negative—one negative case giving a positive syphilis test. Out of the thirty-eight cases, thirty-five were treated, the treatment consisting either of the administration of arsphenamin or of inunction of mercury and protoidid by mouth or mercury salicylate hypodermically. Marked improvement was obtained in twenty-four cases, five of this number having given a negative Wassermann; slight improvement was present in six cases, one of which gave a negative Wassermann and five a positive Wassermann. Wallace considers the roentgenogram the most valuable factor in the diagnosis of syphilis of bone and joints and in differentiating it from other conditions.

Mensurgraph: Measuring and Plotting Orthopedic Deformities.—The method described by Kilmer consists in using the photographic camera as an instrument of precision the same as a surveyor uses the transit.

Thyroid Extract in Myxedema and Hypothyroidism.—In the treatment of these cases Dock begins with a small dose of thyroid extract, about 1 grain, t. i. d., increases it rapidly until physiologic effects appear, and then reduces the dose until a desired condition has been reached. He advises that the dangers and precautions in such treatment be kept in mind.

Subdeltoid Bursitis.—This paper is based on seventy-five cases. A careful analysis was made by O'Reilly and Ewerhardt in fifty cases. There were twenty-three males; of these, seventeen had involvement of the right shoulder, four of which were the result of trauma. In six, the involvement was in the left shoulder, and of these, two were the result of trauma. There were twenty-six females, showing involvement of the right shoulder in fourteen cases with seven due to trauma. In the left shoulder there were twelve cases, with only three due to trauma. Sixteen cases in fifty gave a direct history of trauma. The great majority of the cases in the men, not the result of direct violence, involved the right arm, which is subject to the hardest use. There were thirteen cases of gradual onset in the right shoulder and only four in the left. In the women the distribution is more interesting. In the right shoulder seven were of insidious onset, while in the left there were nine cases. This would suggest that the left shoulder is more vulnerable in women. Of seven cases in the right shoulder, there were two laundresses, one nurse, one "cap shop," and one cleaning woman. All of these occupations would mean a more active use of the right arm. Practically all the housewives had bursitis in the left arm. It may be that housewives have some especial type of work that tends to traumatize the left arm, possibly sweeping. As for treatment, uniformly good results were obtained by means of massage, heat and proper manipulations.

Early Sign in Influenza (Epidemic Pneumonitis).—On examining the records of 300 cases of influenza in which the first symptoms of the disease had developed within twenty-four hours of admission and in which there were no physical signs of consolidation, a sign was recorded so often that Stine regards it as being diagnostic of beginning influenza. In 83 per cent. of the cases, there was a description of "cog-wheel inspiration," or "harsh inspiratory puff," in the record of their entrance examination. These terms were used to describe a physical sign met with on auscultation of the chest. On listening to the breath sounds over the chest, the examiner heard in the lower left back, left axilla, left apex, right apex or right back (mentioned in the order of their frequency), an inspiratory sound more intense and harsh than over the rest of the chest and either broken into "cogs" (a series of inspiratory puffs) filling all the inspiratory phase, or the inspiratory sound was more intense and harsh than over the rest of the chest, but filling only part of inspiration and resembling a single harsh, short puff. The expiratory sound is absent. Stine looks on the presence of this sign as important in diagnosing influenza. It can be differentiated from the harsh breathing that precedes bronchial breathing over a beginning consolidation, by the absence of the expiratory sound. In bronchial breathing the blowing tubular sound appears first during expiration and as the sounds become more intense and harsh, inspiration and expiration are made up of two sounds of about equal intensity and length with a pause between.

Control of Malaria by Treating Malaria Carriers.—This is one of a series of papers, based largely or entirely on malaria control work conducted jointly by the International Health Board and the Mississippi State Board of Health, in a locality of great prevalence in the Mississippi delta. Experimental control of malaria by treating malaria carriers in Bolivar County, including all methods experimented with and all groups of people, was followed by a reduction of 35.52 per cent., the best for any subdivision being 83.82 per cent. reduction. In Sunflower County, during 1918, in an area of 100 square miles, having a population of over 8,000, the reports of the physicians of the area indicated a reduction of 88.82 per cent. In a subdivision of the area, 440 persons were resurveyed just one year from the date on which they were surveyed and put on treatment. This resurvey indicates a reduction of 89.9 per cent. over the frequency of malaria attacks during the year previous to their first survey and treatment. In Bass' opinion, the conclusion seems justified, that it is practical to obtain a high degree of malaria control in localities of great prevalence in the Mississippi delta by proper treatment of malaria carriers.

Duodenal Fistula.—The fistula in Hendon's case had its origin in an ulcer of the duodenum which destroyed the mucous and muscular wall and produced a pinhole leak in the peritoneal covering; pain and chills and fever were the result of the escape of a few drops of duodenal contents into the surrounding tissues. Improvement of the patient after the chill was due to a temporary closure by lymph deposits over the leak, and subsequent chill and fever were the result of dislodgment of the protecting patch of lymph. This long-continued and intermittent escape of minute quantities of irritating material resulted in the formation of a defensive system of protective adhesions. The discharges were controlled by plugging the opening in the intestine with gauze saturated with compound tincture of benzoin. The fistula closed itself after five weeks.

*Use of Influenza Vaccine as Prophylactic: Experimental Study Conducted by Massachusetts State Department of Health. W. A. Hinton, Boston, and E. S. Kane, Monson, Mass.—p. 442.

Use of Influenza Vaccine as a Prophylactic.—An experimental study was conducted by the Massachusetts State Department of Health to show the necessity of properly controlled experiments to determine the value of a prophylactic remedy during an epidemic. A report of this work is made by Hinton and Kane. The vaccine used consisted of two strains of influenza bacilli, obtained during the present epidemic, one strain being recovered at necropsy and the other from the nose of an infected patient. These organisms were grown on blood agar for from sixteen to twenty hours, suspended in salt solution and heated to 55 C. for twenty minutes. One cubic centimeter of the vaccine contained approximately 800 million organisms. The vaccine was given intramuscularly, at twenty-four hour intervals, into the deltoid and triceps muscles. The injections were 0.5 c.c. on the first day, 1 c.c. on the second day and 1.5 c.c. on the third day. Children under 12 years of age were given one half these quantities. The results obtained were entirely negative. The work was done in an institution in which influenza had not yet made its appearance, the Monson State Hospital for Epileptics, representing a small colony of individuals ideally suited for the purposes of this experiment. Approximately half of the patients were vaccinated, and as far as possible this was done by vaccinating a patient in every other bed of a ward or room. Careful records were kept on 225 patients aged from 4 to 70 years, as to the local and constitutional reactions of the vaccine. No reaction was noted in 184; twenty-six had headache and vertigo; fifteen had cough and coryza. In addition to the forty-one patients who gave reaction, eight gave severe reactions with all of these symptoms. In spite of the fact that the number of injections and the quantity of each injection was the same for each vaccinated individual in this institution, constitutional symptoms were relatively no more frequent in the young than in the older patients. Forty-one patients showed mild constitutional symptoms of influenza, consisting of rise in temperature or nausea or vomiting or coryza or headache. The duration of symptoms was for twenty-four hours or less. The constitutional reaction almost invariably occurred within an hour or so after the second injection. Among the tuberculous patients, the constitutional effects of the vaccine, as far as could be noted, differed in no way from those without this pulmonary complication. In tabulating the results of the epidemic, it was noted that some of the patients having the severest reactions from the vaccination developed influenza, although the interval was from four to thirty-six days after receiving the vaccine. Therefore, the reaction from vaccination did not indicate the susceptibility of the individual to infection, neither did vaccination have any demonstrable effect on the course of the disease. Although the patients consisted almost entirely of epileptics, influenza seemed to have no effect on the number of seizures of infected individuals. In addition to the experimental study carried on in Monson State Hospital, the same influenza vaccine was used for prophylaxis in other state institutions. For one reason or another, no conclusive proof as to value of the vaccine as a prophylactic could be obtained in any of them.

Physics of the Chest.—The physics of the chest and their relation to the diseases and injuries of the thoracic organs are discussed at length by Barr. He first speaks of the intrathoracic pressure in health, reviewing briefly various experiments and clinical work done to maintain intrathoracic pressure during operations on the chest and its contents. Then he discusses the physics of hemothorax, pleurisy, atalectasis, the lung reflexes, the treatment of pleural effusion and the use of drugs in the restoration of the function of the damaged lung. One drug—common salt—should, he says, as far as possible, be eliminated from the diet, especially in cases of serofibrinous pleurisy, on account of its high osmotic equivalent. When there is a large quantity of effused fibrin, as occurs in pneumococcal pleurisy, decalcifying agents, such as lemons, citric acid, the citrates of ammonium, potassium and sodium may be used. In Barr's opinion, it is well to reserve their use until the acute stage of the accompanying pneumonia has passed, as the lime salts are the most important drugs in the treatment of that disease. In order to hasten the solution and absorption of the effused fibrin there is no objection to the introduction of a small amount of trypsin into the pleural cavity. The injection of a few ounces of sterile liquid petrolatum, which has a lower specific gravity but a higher surface tension than the normal lubricating fluid, lessens the liability to pleural adhesions. In empyema the lung is always more or less collapsed, and in any operation the object should be to avoid any further collapse and to make the lung expand so as to drive the purulent fluid out of the chest. Pneumothorax, visceral hernia into the thoracic cavity, emphysema, asthma, bronchitis, pneumonia, influenza, laryngeal diphtheria and croup, adenoids, whooping-cough and mediastinitis are all considered in this paper.

War Headache and Its Surgical Treatment.—All the cases of war headache in which Rawling did a decompression operation were secondary to gunshot wounds, concussion, fractured base, etc. First of all, he found that: 1. The more severe headaches are associated with an intact skull (closed box) or with small defects. With large deficiencies headaches are less frequent. 2. Frontal and temporal injuries are more commonly accompanied by headache than injuries in the parietal, occipital and cerebellar regions. 3. Wounds near the vertex, in relation to the superior longitudinal sinus, are frequently associated with a severe type of headache. 4. The presence of foreign bodies within the skull is commonly accompanied by chronic headache, more especially when the foreign body is situated in relation to the ventricles of the brain.

In the great majority of cases the headache dated from the moment of recovery from unconsciousness, either from the injury itself or from the operation carried out for the injury. The very first thing that the patient remembers is headache, at first very severe. In many cases special note is made of that point, and in some cases lumbar puncture was carried out for its relief. Previous to transference home the pains abated somewhat, and soon after arrival reached a certain standard. It is on this standard that Rawling gages the diminution, chronicity or increase of the pains. The severity of the headache varies greatly, from mild and inconstant attacks through every degree and grade of headache to the most severe and persistent pains. Perhaps the most common type is a "cyclic" headache. In other instances the pains show little variation in degree, persisting both day and night without intermission; the patient is never free from some degree of headache, varying from "dragging," "weight," "tearing" sensations to a constant dull ache. Wherever the injury, these headaches tend to become localized to the frontal region—behind the eyes—perhaps more acute on the side injured. Often, also, reference is made to the temples. Sometimes also there is a maximum "bursting" pain over the summit of the vertex. In addition to the fact that mental or bodily exertion, noises, joltings, concerts and especially movies, all tend to start the headache or add to its severity, there appear to be two special times of headache development—in the early morning on awaking, and in the evening between tea and bedtime. Associated symptoms are slowing of the pulse rate, with but little raising of blood pressure; marked giddiness; frequent elevation of temperature, night after night; insomnia; slow cerebration; tendency to exaggeration of all reflexes; nausea is uncommon; vomiting is rare; fits, generalized, epileptiform and eye symptoms. These headaches are dependent on some general increase of intracranial pressure, and this in turn is due in the great majority of cases to excess cerebrospinal fluid (cerebral edema).

Rest, dietetics, drugs and lumbar puncture failing to give relief, Rawling urges the performance of subtemporal decompression which will almost certainly bring about relief or cure within forty-eight hours of the operation without in any way risking the patient's life and well-being. A brief summary is given of twenty cases of subtemporal decompression carried out for the relief of headache, chronic and severe, the result of gunshot wound or other injury of the head, the headache leading to total incapacitation and rendering the sufferer utterly miserable. In the majority of cases the patient requested operative measures, all other remedies having failed.

Influenza Among Poison Gas Workers.—The information given by Shufflebotham with regard to influenza among poison gas workers has been collected from twenty different sources in different parts of the country; it all points in the same direction—that with the exception of phosgene gas, workers engaged in the production of other poison gases have enjoyed a very high degree of immunity from influenza infection. It is agreed, on the other hand, that phosgene workers are peculiarly susceptible to influenza, and that the disease, when contracted, assumes a serious course.

Antimony Tartrate in Bilharziosis and Tachycardia.—Christopherson points out that the tachycardia following the intravenous injection of antimony tartrate may not be due to antimony tartrate at all, or at most only secondary to it; it may be due to a totally different cause—to other parasites, for instance—although at the same time bilharzia may be present. Therefore, Christopherson urges that the feces should always be examined for parasites while antimony treatment is on its trial.

Variety and Latency of Organisms on Missiles in the Tissues.—Missiles apparently sterile, or at least giving no clinical indication of infection, were examined bacteriologically by Pybus and his associates. The missiles were extracted for varying reasons, either because they were subject to pressure or caused pressure on nerves, or interfered with movement. Forty-four specimens were sent for examination; nearly 50 per cent. were sterile. Of twenty-three missiles from which cultures were obtained, the staphylococcus was present in ten cases. Putrefactive bacilli, in six cases, were next in the order of frequency. In two cases the tetanus bacillus or organisms of that type were found. The analysis shows that shell fragments, contrary to what might be expected, are more often sterile than bullets. The length of time the missile remained in the tissues varied from one to thirty months. This examination has shown that the *Bacillus perfringens* may survive a period of seven months. In this case the bullet was removed from the tibia, where it was lying without causing any apparent lesion in the surrounding cancellous tissue. After removal no ill effects followed, and the wound healed by first intention. In a second case a fragment of shell was removed from the forearm. Streptococci and the tetanus bacillus were found. The wound suppurated, and immediately on receipt of the bacteriologic findings antitetanic serum was administered; no symptoms presented themselves.

Inunction of Creosote in Pneumonia and Influenza.—The axillary inunction of creosote in pneumonia and in influenza and some allied conditions is advocated by Wells. The method of administration is simple. For adults, 10 minims of pure creosote are gently rubbed into the right axilla with the finger. If necessary, which is very rarely the case, a second dose may be given, this time in the left axilla for fear of blistering. The patient must be dressed in woolen or flannel and placed between blankets so as to avoid a chill after the sweating. Only slight discomfort attends the treatment; a slight burning of the skin, which passes off in a day or two without vesication, is the only disagreeable effect. For children Wells has diluted the creosote with soap liniment, reducing the proportion of creosote according to the age of the patients. For infants, in place of the axillary inunction, he has at times substituted rubbing the neck and front of the chest with a liniment containing creosote. Practically all cases of influenza under his care have been treated by rest in bed (most of them a soldier's bed—that is, on the ground), plenty of fresh air, and the administration of creosote by the mouth. Half a minim of creosote shaken up with half an ounce of water is the simple mixture—the addition of half a minim of oil of peppermint makes it more palatable, but it is not very unpalatable without it. Very few patients treated in this way develop pneumonia. When signs of pneumonia developed the axillary inunction of creosote was nearly always followed by its abortion, or it was so modified that the patient recovered. When the pyrexia of influenza has gone, quinin or strychnin or both may be necessary.

In several cases of meningitis due to infection by *Micrococcus catarrhalis*, and one by meningococcus, the patients recovered after axillary inunction. Wells believes creosote to be particularly detrimental to the pneumococcus, the *M. catarrhalis*, and the influenza germ, and that creosote administered by axillary inunction enters the blood stream through the lymphatics, and is taken direct to the lung tissues by the pulmonary circulation, possibly taking a short cut into the blood stream by the lymphatic duct. Its diaphoretic action helps to relieve the hyperemia of the lung tissues, and thereby removes the nidus for the pneumococcus which might be formed by an exudate; its antiseptic action is brought to bear directly on any germs that may have gained access to the air spaces of the lungs.

Use of Sensitized Influenza Bacillus Vaccine in Treatment of Influenza. J. Nogata.

April 20, 1919

*Prophylactic Inoculation and Vaccine Treatment of Influenza. T Kitano.

Vaccine in Prophylaxis and Treatment of Influenza.—A sensitized influenza bacillus vaccine has been used by Kitano as a prophylactic and therapeutic measure in influenza with good results. For prophylactic use the vaccine contains 0.2 mg. of the bacilli in 1.0 c.c. of suspension. Among 10,300 persons who were given this treatment, only 285 (2.7 per cent.) had any untoward symptoms, such as local pain and swelling, chilliness, pyrexia—usually slight in degree, headache, anorexia, insomnia, vomiting and diarrhea. In none of these cases were the symptoms of long-duration and rarely were they of any great degree of severity. The same vaccine was used for therapeutic purposes. The dose was the same. The injections were repeated at two days intervals, sometimes as often as six times, until the symptoms disappeared or began to disappear. Eighty-seven patients were treated. In forty-nine the course of the disease was uneventful; in thirty-eight pneumonia was a complication. The mortality among the former was nil; in the pneumonia group it was 5.2 per cent. In 270 cases of influenzal pneumonia treated in the usual manner, the mortality was 23 per cent. With the usual treatment the average number of sick days was 17.2, while in the vaccine treated cases the patient was never ill more than ten days, usually only seven, after the first injection of vaccine. In short, the vaccine lessens the period of illness and lowers the mortality.

*Vaccine Therapy of Contagious Lymphangitis in Horses. M. Belin.—p. 314.

International Scientific Relations.—See news item, p. 1477.

Contagious Lymphangitis in Horses.—Belin reports experiences with 1,500 horses presenting bacillary lymphangitis and 400 with cryptococcus lymphangitis, all treated with a pyovaccine. This treatment proved successful in about 75 to 98 per cent. of the cases. It is superior to all other procedures applied to date, he says, while not conflicting with any of them. He describes three methods for preparing the vaccine. The one he has used most is made by agitating vigorously together pus, taken from ripe abscesses, with four parts of ether. It is then set aside for twenty-four hours, agitating occasionally. Then as much boiled water is added as was used of the ether, and the pyovaccine is ready for use. In recent cases of cryptococcus lymphangitis, he injects 2 c.c. in series of seven daily injections, then waits twelve or fifteen days before the next series. With bacillary lymphangitis, he uses 3 c.c. in four daily injections, and then continues with isolated injections, one every five or six days.

Fractures Treated in Germany. A. Bréchot and R. Massart.—p. 400.
The Fifth Cusp is of Atavistic Origin. M. Baudouin.—p. 402.

Epilepsy.—Mirallié has now a record of 183 epileptics treated with the usual sedative plus a salt-free diet. No benefit was apparent in 20 cases; failures are usually in homes where servants are kept. Improvement was manifest in 52 cases, with the disappearance of all seizures in 3. When he found it impossible to get bread made without salt, he had potatoes used instead of bread. The age and the duration of the epilepsy did not seem to affect the result.

This salt-free diet was kept up at least four or five years. His patients gradually came to prefer unsalted food. There was no restriction in the diet otherwise. In 60 per cent. of 161 followed to date, the seizures have not returned. In some the interval is up to twelve years.

Influenza Among the Tuberculous. P.-J. Ménard.—p. 101.
Syphilids in the Axillae. Guerquin.—p. 106.
*Anachlorhydria and Apepsia. F. Ramond.—p. 106.
*The Wassermann Reaction with Chronic Splenomegaly. P.-E. Weil.—p. 111.
*The Leukocyte Balance with Cardiac Instability. C. Laubry and C. Esmein.—p. 115.
*Treatment of Acute Rebellious Dysentery. G. Cotti.—p. 119.
Influenza in Public Hospital. M. E. Lenoble.—p. 125.
*Muscle Signs of Sciatica. Chiray and E. Roger.—p. 129.

Anachlorhydria and Apepsia.—Ramond relates that he found anachlorhydria in 11 per cent. of 340 dyspeptics and apepsia in 0.5 per cent. The anachlorhydria can generally be traced to some infection or intoxication, or to nervous action. Acute carbon monoxid poisoning is sometimes responsible for the anachlorhydria, but alcohol was the most common cause; it was evident in 15 per cent. Hayem incriminates tobacco, but Ramond says that tobacco acts more as a stimulant of gastric secretion. Nervous influences were undoubtedly responsible in certain cases, but they were rare. Melancholia and neurasthenia with a tendency to melancholia were sometimes accompanied by anachlorhydria. Persons with anachlorhydria are small eaters as they thus spare themselves discomfort. For the same reason they avoid meat, fresh bread, beans and peas, wine and coffee. Fatigue and working immediately after meals also induce discomfort. They may also complain of a bitter taste in the mouth on waking, and after meals there is oppression and often nausea with vomiting, sometimes at once or not until late. In nearly 80 per cent. of such patients there is no tendency to dilation or ptosis of the stomach, but rather the reverse, and evacuation is relatively rapid. The anachlorhydria is generally definite or at least of long duration, and it was not modified in his experience by a meat diet or with pig or dog gastric juice or salt, but alkalines often promoted digestion. On a strictly egg, milk and vegetable diet, the symptoms usually disappear.

Wassermann Reaction with Chronic Splenomegaly.—Summarized on page 1398.

Leukocyte Balance with Irritable Heart Action.—Laubry and Esmein state that mononucleosis was evident in twenty-two out of thirty persons with *instabilité cardiaque*. At the same time, there was no relation between the leukocyte formula and the degree of the heart instability or its duration. The leukocyte reactions do not display constancy or fixity enough to be regarded as a fundamental symptom of pathogenic import. In three soldiers with exophthalmic goiter, the leukocyte formula was found normal on three separate examinations.

Treatment of Dysentery by Appendicostomy.—Cotti has treated seven cases of acute rebellious dysentery by systematic flushing of the large intestine with a 1:1,000 solution of silver nitrate introduced through the appendix. The appendicostomy was done under spinal anesthesia. The usual measures had all been tried before to no avail. The dysentery seemed to be of the Shiga type and two of the men succumbed to the profuse hemorrhages which persisted after the intervention or to the progressive severe ulcerations.

Muscle Signs of Sciatica.—Chiray and Roger call attention to the *signe de la pointe*, that is, the inability, with sciatica, to stand on tiptoe. The insufficiency of any one of the three groups of muscles involved prevents assuming or at least holding the tiptoe position. (See also, page 1497, a summary of their previous communication on this subject.)

Splenectomy for War Wounds of Spleen; Three Cases. Drouin.—p. 91.
Impressions on Medical Mission to Russia. P. Pietri.—p. 96.

Intrapulmonary Injections in Pneumonia.—Mauriac has only eighteen cases to report and three of the patients died, but in the others the exceptionally grave influenzal pneumonia seemed to have benefited remarkably by the injection directly into the lung tissue of antipneumococcus serum. The lung tissue seemed to bear the injection well. In only half the patients was there even coughing. It is better to withdraw the needle if the coughing is violent; this lesson was taught by one case in which the jerking around of the needle during coughing was followed by a minute hemorrhage. He used a 20 c.c. syringe with a needle 10 or 12 cm. long, pushed gently directly into the lung tissue at the focus of the pneumonia, thus injecting 20 c.c.

*Infirmary for Infants. H. Méry.—p. 65.
*Habitual Vomiting in Infants. A. B. Marfan.—p. 76.
Study of the Blood and Blood-Producing Organs in Infants. G. L. Hallez.—p. 102.

Infant Infirmary.—Méry reviews the experiences of the last three years at the Médan infirmary which receives infants under 2 suffering from gastro-intestinal derangement. The absolute necessity of breast milk for young infants is emphasized anew by the data presented. After the fifth month they can get along without it, and Méry protests against infants younger than this being sent to the infirmary, as breast milk is not available there. Especially gratifying have been the results of placing infants in families, particularly those taken from homes where there is tuberculosis.

Vomiting in Infants.—Marfan calls the vomiting in the absence of any primary lesion in the stomach, the "disease of habitual vomiting in nurslings." It is evidently a nervous trouble; the gastric mucosa is unduly sensitive, and after each feeding there is a gastro-spasm and the stomach casts up more or less of its contents, breast milk or artificial food, as the case may be. It is a gastric neurosis, which explains the variability of the findings in the chemistry of the stomach and of the stools. If the spasms include the bowel there is constipation. Excessive swallowing of air may complicate the clinical picture. Infants inclined to habitual vomiting generally display a neuropathic tendency. Sometimes a complete change of environment may prove effectual when all else has failed, although the improvement may be only temporary. In other cases, treatment as for inherited syphilis gave sometimes surprising results. The vomit in these cases is usually a colorless fluid, made up of the whey of the milk, swallowed saliva and gastric juice, with floating clots of milk, as the vomiting does not occur at once, not until after fifteen or thirty minutes or an hour or an hour and a half or more after the feeding. The vomiting may occur without effort, or the child may be restless and scream and appear relieved after the vomiting. Sometimes abruptly moving the child may bring it on.

Recent Literature on Syphilis. G. Milian and Burnier.

The Arsphenamin Question.—Milian discusses the disturbances which may follow the use of arsphenamin, especially what he calls *la crise nitritoide* and *l'apoplexie séreuse*. He says that they are both due to the vaso-dilating action of the drug, and epinephrin prevents and cures them. When the drug has not been rendered sufficiently alkaline, it is almost certain to induce congestive phenomena. Neoarsphenamin never induces the nitritoid crises except in extremely predisposed and intolerant persons. By watching for signs of intolerance under graduated treatment, it is possible to guide the doses so as to avoid them. Headache, vomiting, or diarrhea, coming on a few hours after the injection or the next day are gross signs of lack of tolerance. Headache, however, may be merely from a Herxheimer or other reaction and not from the toxic action of the drug, but as it is impossible to distinguish between them, it is better to err on the safe side and not increase the dose unless mercury corrects the tendency in the interval. Lacrimation, watery nasal discharge, excessive secretion of saliva and increase in the size of the testicle are minor signs warning of the impending nitritoid crisis or serous apoplexy, but the most certain and safest guide is the temperature, taken every three hours, the day of the injection. If the temperature goes above 38 C. (100.4 F.) there is marked intolerance. If this occurs with each injection, with the same dose, it might be preferable to drop this drug. A temperature between 37.8 and 38.2 C. the second and third days also testifies to intolerance, and calls for extreme prudence. Epinephrin given promptly at this time will ward off serous apoplexy. Milian remarks that the patients display an incredible carelessness to this important point of recording the temperature every three hours. It is an extremely reliable guide, and its warnings should never be disregarded. The only fatality Milian had from arsphenamin at the center in his charge during the war was of a man whose temperature of 39.5 C., two days after his sixth dose of 0.9 gm. arsphenamin, was ascribed by the attendant to influenza, and Milian was not notified until thirty-six hours later, when fatal coma was already installed. He is confident that if he had taken the proper measures at the critical forty-eight and seventy-two hours, this death might have been avoided. This has been his constant experience in other cases.

He expatiates further on the imperative necessity of making the injection very slowly. By taking ten minutes for it, the injection can be suspended any moment if immediate accidents develop. The syringe is responsible for certain fatalities that might have been avoided by pouring instead of squirting the fluid into the vein. He knows of one man who died on the table from an ultraviolent nitritoid crisis as soon as the concentrated solution of neoarsphenamin had been injected from the syringe. The syringe had also been used in a recent medicolegal case in which the woman died in the physician's office. The syringe is more convenient for the physician, but the patient loses in safety. He suggests further that it is a good plan to adopt the antianaphylaxis precaution of injecting a minute amount such as 1 c.c., and then waiting for fifteen seconds, then inject the same small amount and again repeat this, before allowing the whole amount to enter the vein. This should be the rule for the first injection at least. He does not approve of the practice of giving epinephrin systematically in every case before giving the arsphenamin. He says that this is like the ostrich hiding its head in the sand so it will not see danger. It deprives the physician of the guide as to the tolerance of the patient. There is danger then of unwittingly giving too large a dose. By heeding all these points, Milian exclaims in conclusion, the physician can give arsphenamin effectually and safely. Any neglect of any of them is liable to have fatal consequences.

The Serodiagnosis of Syphilis.—This entire number of the *Paris Médical* is devoted to syphilis, and there are several articles on the technic and nature of serodiagnosis.

Gastric Syphilis.—Azémar reports three cases in which a course of mercury and arsphenamin was tentatively instituted as a last resort before operating for supposed malignant disease of the stomach. Under this treatment the pain, tumor and cachexia promptly disappeared under the arsphenamin; more slowly under the mercury. There had evidently been gummatous infiltration of the wall of the stomach.

*Influenzal Purulent Pleurisy. L. Bérard and C. Dunet.—p. 169.
*Migraine. P. Pagniez, P. Vallery-Radot and A. Nast.—p. 172.
Inter-Crico-Thyroid Intratracheal Injections. R. Rendu.—p. 174.

Treatment of Purulent Pleurisy.—Bérard and Dunet give an illustrated description of their method of draining at the very lowest point in the side, toward the front, with a counter-opening at the back through which the cavity is flushed out occasionally. Two Carrel tubes are inserted in this posterior opening, the ends of the tubes brought up high on the back and held in place with a strip of plaster. The patient is got out of bed early, not later than three or five days after the intervention. In 26 cases of post-influenzal purulent pleurisy, 5 of the patients died before this treatment could be fully applied. The others recovered, and in half the time required for recovery with other methods of treating empyema of the great cavity. In 5 cases the pneumococcus alone and in 10 plus the staphylococcus was involved; in 4 the pneumococcus and streptococcus, and in 2 the latter alone. They begin with an evacuating pleurotomy; then the anterolateral drainage is installed, and then the solid pus, which has accumulated like actual false membranes, is swabbed out. It is these accumulations which keep up the trouble; he swabs them out with a sponge or wick on a long forceps, working from the back forward, concluding by introducing the Carrel tubes from the rear. The drainage and the flushing out of the cavity with some antiseptic every three hours during the day should be carefully supervised. The patient should be left in peace the first twenty-four hours after the intervention; he should be quite cured in one month. Similar cases given treatment by other technics took sixty or seventy days before the cure was complete.

Prevention of Migraine.—Pagniez and his co-workers, three years ago, reported a case of severe recurring urticaria of alimentary origin which they cured by having the subject eat a small amount of the toxic substance in question one hour before the meal. This practical application of the laws of anaphylaxis proved completely successful in this and several similar cases, showing that the first case was not an exceptional instance. The same reasoning and treatment was applied to migraine, and it has proved remarkably effectual in the five cases here described. The five men and women had been subject to migraine for years, rebellious to all measures. Then one took 0.50 gm. of peptone half an hour before the two principal meals for two weeks, and was free from migraine during that period and for six days after its suspension. Then he had an attack, and resumed the peptone for five weeks and had no further attacks during this period or afterward for six months except a slight headache every ten or fifteen days. At the end of the six months the migraine returned every day, moderately intense. The peptone was resumed for three weeks, and there was no further migraine for nearly two years.

The man's life was completely transformed by the success of this treatment which had not only freed him from the distressing and incapacitating migraine but the functioning of the digestive tract had been transformed as well, losing his flatulence, drowsiness after meals and distress after eating meat and eggs. This patient was a man of 34 who had been subject since the age of 10 to "sick headaches" twice a week, with intense migraine about every six weeks. All the five patients seem to have been definitely freed by the courses of peptone from their tendency to migraine. Other cases of migraine were not modified in the least by the use of peptone. By examining for what Widal calls the *crise hémoplasique* we may be able to distinguish the cases in which this peptone treatment will succeed. It is based of course on Besredka's method now commonly used in serotherapy for warding off anaphylaxis by a small preliminary injection of the antiserum. Its success in certain cases of migraine seems to rank this malady as an alimentary anaphylaxis.

April 7, 1919, 27, No. 20

*Plasma Therapy in Influenza. E. Lesné, P. Brodin and F. Saint-Girons.—p. 181.
*Hernia of the Colon. G. Labat.—p. 182.
*Minor Signs of Aerophagia. G. Leven.—p. 184.

Intravenous Injection of Human Plasma.—Lesné and his co-workers state that citrated plasma is less toxic than out. If the reaction is *strong, it occurs* in less than two minutes; a medium reaction takes three or four minutes, and after the fifth or sixth minute the reaction has no significance. The response is more *sensitive* than the Nonne, Apelt, and Noguchi *reactions. The most intense* reactions were observed in cases of meningitis. He describes four cases in detail in which the diagnosis of meningitis seemed certain, but the negative Boveri turned the scale to exclude *meningitis;* its *findings* were *confirmed by* the course of the cases.

Amazonas Medico, Manaos

June, 1918, 1, No. 2

Blunder in Diagnosis: Fetus in Pouch of Douglas from Tubal Pregnancy. J. de Moraes.—p. 1.
*Colored Urines. F. Vidal.—p. 4.
**Intestinal* Schistosomiasis. A. da Matta.—p. 9.
*Leishmaniosis of Skin and Mucosa. A. da Matta.—p. 11.

Colored Urines.—A young man in the hospital, on account of chronic *nephritis,* began to void green urine, and the liver showed signs of congestion. Chemical tests of the urine *showed the* presence of biliverdin. The patient soon died. Widal knows of a second similar case, and he reviews the various types of colored urine that may be encountered, white, blue, violet, green, red or black. One man of 46 had been taking 3 gm. of tannin daily for some time, and his urine turned black under the action of oxygen. The sweat may also be of abnormal color. A case has recently been recorded at Bahia which presented typical polychromidrosis.

Intestinal Schistosomiasis.—Da Matta publishes what he thinks is the first case of this *kind that has* been diagnosed in the Amazonas region. Intestinal pains, congestion of the *liver, jaundice and alternating* constipation and *diarrhea* were explained by the lateral-spined ova of the schistosomum in the stools. The snails known to be the intermediate hosts of the parasite are common at Manáos. He mentions that Martinez of Porto Rico was *the* first to demonstrate the occurrence *of* schistosomiasis *in* natives *of* America.

Leishmaniosis of Skin and Mucosas.—Da Matta quotes from early writers to the effect that the grave form of leishmaniosis affecting the skin and mucous surfaces was described as early as *1759.* The pottery of the Incas shows reproductions of it from before the discovery of America. Certain regions in Peru seem to be the focus of the disease, but in the course of centuries it has spread from Bolivia and Amazonas to Paraguay. Popular synonyms for the disease are, besides oriental sore, uta and espundia, gallico, kjapa, *tiac-araña,* jaccuya, quecpo and llaga. Da Matta does not discuss the treatment.

*Rabies in Northern Brazil. A. Passos.—*p.* 75.
**Hexamethylenamin by* the Vein with Liver-Kidney Spirochetosis. A. da Matta.—p. 81.
Classification of Leishmanioses. A. da Matta.—p. 86.
Prophylaxis of Influenza. G. Ramos, F. de Sá, M. de Pinho, M. Leão and S. B. Nunes.—p. 93.

Rabies in Northern Brazil.—Passos reports what he says is the first case of rabies in man that has ever been recognized at Manáos. Rio, Pernambuco, S. Catharina, Rio Grande do Sul, and Belem have each now a Pasteur Institute, and Passos pleads to have one organized for Manáos. He relates that many dogs, cats and other animals developed influenza, but there seemed to be just preceding this an epizootic of rabies among the animals.

Latent Chronic Empyema.—The five articles in this issue of the *Blatt* are by Stierlin's present and former assistants and are dedicated to him on the twentieth anniversary of his assuming charge of the Winterthur *public* cantonal hospital. Schweizer reviews the literature on chronic empyema, and reports a case in which the latent empyema was unmistakably of from twelve to eighteen years' standing, and had never interfered with the earning capacity. He has found four somewhat similar cases on record, and in none of them was the empyema suspected. *In his* case the operation was *undertaken* for caries of the ribs. Iselin is right when he warns that we are too ready with the diagnosis of caries of the ribs, and *overlook the* primary lesion within. Sometimes the latent *empyema may* be a necropsy *surprise,* or an acute exacerbation *may* first attract attention to it. The operation in these *old* cases requires resection and removal of the encasing, *often* calcified, cuirass formed by the hardened pleura, and also *removal of* hardened lung *tissue.* In his patient, the pus from the unsuspected bilateral empyema finally worked its way into the *subcutaneous* connective tissue, but it was a *whole* year doing this. In Tuffier's case, this occurred in the course of a *few days.* In Sweet's case, epigastric pain and *vomiting* accompanied it. In Schweizer's case, the lung *expansion returned to* approximately normal after *the second* operation. The earning capacity was regained, but a further *minor operation* is now contemplated. In conclusion he *warns that* even *if* the empyema lies latent for a decade or more, *it is still* dangerous; the dangerous consequences *are only postponed.*

Nephrectomy.—Thellung *reports* a case of fatal paralytic ileus following removal of a tuberculous kidney in a man of 43. The conditions *otherwise* were favorable, except *that* the kidney was drawn up high against the spine, and 165 c.c. of ether had to be used. Of *the* 42 nephrectomies of *the last* twenty years 6 of the patients died from shock or heart weakness *or* a necrotic process in the bowel. The *mortality has* dropped from 30 or 40 to from 3 to 10 per cent. in the two decades. In 16 of the 22 cases of tuber-

Dysentery in Uruguay. A. Gaminara.—p. 800.
**Amebic Tumors in* Large *Intestine. E. P.* Lasnier.—p. 810.
Cecropia Peltata in Therapeutics. M. F. Langon.—p. *829.*
Epinephrin in *Influenza.* A. Ricaldoni.—p. 867.

Latent Cancer of Lung.—In Ricaldoni's case a man of 65 was an *itinerant* peddler who had complained for five months of right suprascapular pain. Finally atrophy and paralysis developed *in the* region innervated by the brachial plexus. There was no dyspnea, no blood in the scanty sputum, and the roentgen and palpation findings were negative. The pains varied, sometimes preventing sleep and again almost disappearing. The man died suddenly one night. An extrameningeal radiculitis seemed most plausible, and its tuberculous nature was suspected. Necropsy confirmed the extrameningeal site of the trouble but showed that it was of malignant nature, a diffuse epithelioma of the lung, with metastases in the pleura and surrounding tissues, presumably secondary. *Five illustrations* and one colored plate reproduce the histologic *findings,* especially the sclerosis in the nerve. Analysis of this case and similar ones on record suggests that some of the cases *of* partial and unilateral paralysis which have been classed as toxic or dyscrasic neuritis, from chronic bronchopneumonia or *pulmonary* tuberculosis, are in reality the consequence of the spreading of the inflammation to the pleural dome. This mechanism was unmistakable in the present case.

Amebic Intestinal Tumors.—Lasnier's illustrated cases demonstrate the *possibility* of amebic inflammatory tumors in the *intestines.* He *reiterates* that this possibility should be borne in mind, and treatment *for* the amebiasis instituted before considering operative measures. The discovery of the ameba *will often* confirm the diagnosis as the tumors otherwise are liable to be ascribed to tuberculosis or other causes.

*Measures Against Malaria in the Orient. S. T. Darling.—p. 265.
*Hashish Smoking. F. de Assis Iglesias.—*p.* 274.

Local Measures Against Malaria.—Darling emphasizes that the measures for prophylaxis against malaria must *necessarily* be local, and that they have to vary with *local conditions.* For example, the drains that last *indefinitely* in a clayey region would be washed out by the *torrential* rains in a more sandy soil. He describes the measures that have proved effectual in the Malay States, especially *the* straightening and deepening of small streams, with *underground* drains. He commends the appointment of an antimalaria board to study local conditions. In the Malay States the board includes the chief of the public health service, a civil engineer, a bacteriologist, a member of the cabinet, a physician, and the owner of a large plantation—each one selected for special experience and skill. The training of the children in prophylaxis of malaria is regarded as important, and posters in several languages serve to warn the populace. The constant intelligent care of the drains, etc., is an important part of the work, as also the determination of the local species of mosquitoes that serve in the transmission of malaria, so that prophylactic measures can be focused on this species.

Hashish Smoking in Brazil.—Iglesias states that *Cannabis sativa* is cultivated in certain regions in the north of Brazil where it is smoked in a special pipe, the smoke passing through water, or in the form of a cigar. He has been experimenting with laboratory animals placed in conditions like those of these human inhalers of the cannabis smoke. The animals showed signs of toxic action, vomiting, paralysis and torpor, but they were transient; the animals had quite recuperated by the end of two hours. Injection by the vein of some of the water through which the smoke had been passed caused no toxic symptoms in the animals. Iglesias describes some special instances of the cannabis smoking vice to illustrate the apparently inevitable mental derangement which its frequent use entails, the hallucinations liable to lead to crime or suicide. The cannabis smokers often form clubs for smoking in common at first, but when they become addicted to the vice they prefer solitude, and gradually fall into the aspect and manners of idiots. The drug is called mostly diamba in Brazil, hashish in the Orient. *Iglesias urges prompt government measures to check this vice.*

*The Work of the Congress on Typhus. E. Landa.—p. 1.
*The Problem of the Etiology of Typhus. A. B. Vasconcelos.—p. 12.

The Problem of the Etiology of Typhus.—The proceedings of the recent Mexican Congress on Typhus were mentioned in the Mexico Letter in The Journal, Feb. 8 and 15, pp. 435 and 508. Vasconcelos pleads for the organization of a special institute for experimental research on tabardillo or typhus, or at least to reestablish the prize instituted by the minister of public instruction, D. Justo Sierra, to stimulate research on typhus and reward the discovery of the causal germ. Until this is realized, antityphus serum should be obtained in ample amounts. He specifies Nicolle and Blaizot's antiserum for the purpose as having given the best results to date.

Jan. to March, 1918, **11**, No. 6

Pterygium. Pathogenesis, Treatment and Prognosis. R. Sauri.—p. 1.
*Eosinophilic Proctitis. A. Lara N.—p. 2.

Eosinophilic Proctitis.—Lara was unable to find amebas or any helminths in 80 per cent. of the stools of young children presenting symptoms of enteritis suggesting dysentery. Scraps of the bleeding mucosa from eighty-seven infants showed a yellow layer of eosinophil cells with granular protoplasm, and numerous Charcot-Robin crystals. The blood count in eleven in this group showed an average of 7 per cent. eosinophils during the acute phase, and of 11 per cent. at defervescence. Necropsy of three of the infants, from 9 to 15 months old, revealed congestion and ecchymotic patches. Along with the dysenteriform enteritis and slight fever, there was sometimes an occasional dry cough, with signs of alimentary autointoxication plus infection, favored by the general depression from teething, the whole presenting a clinical picture like that of eosinophilic proctitis.

*Tuberculin Treatment. J. J. Vitón.—p. 205.
Epizootic Meningitis in the Horse. C. F. Flores.—p. 208.
*Progress in Hygiene in Buenos Aires. E. R. Coni.—p. 212.
*Fluorids and Endemic Goiter. L. Goldemberg.—p. 213.
The Coolidge Tube. C. Heuser.—p. 223.

Tuberculin Treatment.—Vitón says that every day he grows more enthusiastic over the result of treatment of tuberculosis with "ultra small" doses of tuberculin which give, he says, "ultra gratifying" results. By "ultra small" he means 1 per thousand million (A); 1 per ten thousand million (B); or 1 per hundred thousand million parts (C). The more acute the symptoms, the smaller the dose that should be used. He regards any general reaction as distinctly injurious; the persons particularly liable to respond with a general reaction are those inclined to asthma, the febrile cases, certain dyspeptics, and certain persons with painful rheumatism. He makes these ultra small doses by taking one part of a 1 per ten million dilution and diluting it with nine parts of a ¼ aqueous solution of phenol. He found further that symptoms following a reactive dose of tuberculin subsided under a following ultra small dose of the same tuberculin.

Progress in Public Health in Buenos Aires.—Coni's statistics confirm that the progress in sanitation, etc., during the decades since 1858 have reduced the annual death rate per thousand inhabitants from 37.3 to 15.2; in 1917 it was only 13.7. "The second largest Latin city has thus reached a death rate which compares favorably with the large cities of England, supposed to be the healthiest in the world."

Pathogenesis of Goiter.—Goldemberg noticed that fluorids seemed to check oxidations by animal oxidases in vitro. Administered to young rabbits in minute, repeated doses, this action was confirmed by the drop in temperature which followed each dose. Later there was a hyperthermic reaction which lasted several days. No influence on the thyroid was perceptible. Perhaps larger animals, dogs and goats, might have had the thyroid affected more.

Introduction to Study of Surgery. J. G. Capdevila.—p. 235. Cont'n.

Treatment of Morphin Addiction.—Juarros remarks that morphinomania is becoming every day more and more common in Spain, while there is a lack of adequate institutions for its treatment. He does not approve of sudden withdrawal of the drug, but prepares the patient for it with a course of alkalines to combat the hyperacidity common in morphin addicts. He gives the alkalines in the form of Vichy water to drink or by injection, and sodium bicarbonate in injections. He prefers subcutaneous injection of the Vichy water, increasing gradually from 1 to 100 gm., or a 4 per thousand solution of sodium bicarbonate in isotonic saline. If the patients object to the injections, the alkaline has to be taken as a beverage. The alkaline treatment is merely an adjuvant, but he regards it as a powerful aid.

*Fracture of Neck of Femur. J. A. Korteweg.—p. 513.
Rapid Infectious Gangrene of Penis. D. B. Boks.—p. 519.

Strophanthin Treatment.—Lankhout found that the irregular heart action and pulse of 160 failed to respond to digitalis in the woman of 40, but marked improvement followed injection of 0.00025 gm. strophanthin. This effect was constantly realized by the strophanthin, and he finally had the woman take this drug systematically over long periods. By this means he kept her cardiovascular apparatus in comparatively good condition. The injections were given with several days' intervals, and no untoward by-effects were observed from the thirty-two injections in this case or the nineteen in a second, similar case of this pulsus irregularis perpetuus.

Fracture of Neck of Femur.—Korteweg discusses Noordenbos' method of treating fracture of the neck of the femur by driving a peg through into the head, axial to the neck. He uses a peg cut from the fibula, but this breaks *so* readily that Korteweg proposes an ivory peg as more suitable. He thinks this method is applicable only for young healthy persons, and after reduction of any invagination.

*Retention of Chlorids in Uremia with Convulsions. J. Holst.—p. 113.
*Retroperitoneal Sarcoma. P. Bull.—p. 145.
*Isolated Bladder Tuberculosis. E. Platou.—p. 151.
*Nitrogen in Urine and Blood. H. Salvesen.—p. 157.
*Infectious Jaundice. L. Nicolaysen.—p. 170.

Retention of Chlorids in Uremia with Convulsions.—Holst reviews the research in various countries which has led to the conception of "chloridemia"—analogous to azotemia—to express the condition resulting from the inability of the kidneys to eliminate chlorids. The clinical manifestations for which the retained chlorids are responsible (according to Widal), include headache, vomiting, respiratory disturbances, convulsions and coma, and possibly the eclamptic *equivalents*: paralysis, amaurosis and tendency to deafness. This clinical picture is identical with that of eclamptic uremia, but Holst proceeds to show by detailed study of 9 cases of varying types that these manifestations cannot *be ascribed to the concentration of the chlorids in the blood* serum. When the chlorids are retained, enough water is always retained with them to keep the concentration practically at a constant level. It is the retention of the water *necessary for this* that causes the trouble, the brain, lungs and viscera becoming edematous. In 2 of the cases presenting the classical picture of chloridemia, the chlorid content in the blood was high, 6.5 or 6.7 per thousand; urea 0.283 or 0.258 per thousand. In 2 other cases with symptoms of pure uremia with convulsions the chlorid content was within normal range: 6.2 and 5.9, with urea 0.36 and 0.25. In another group of 2 the chlorid content of the blood was high, 7 and 6.6, but one had never shown any symptoms of disturbance from retention of urea or chlorids, and always felt subjectively well in spite of his amyloid kidney; the other had apparently sound kidneys and was clinically normal except for slight gastric hyperacidity. Two other patients, one a parturient, exhibited symptoms typical of uremia with convulsions, but the chloridemia of the blood kept low, not over 5.5 and 5.9, although the uremia was so extreme that death soon followed.

It is the secondary retention of water that brings on the clinical picture that has been labeled "chloridemia": the edema in the brain and viscera. Treatment should include abstention from salt, but if the urea in the blood is within normal range, and if the phenolsulphonephthalein test shows normal conditions in this line, then the patient can be given milk in increasing doses, gradually resuming fish and meat, merely keeping the salt intake low. Milk is useful on account of its high albumin content and its low salt content. It may seem strange to allow albumin to these patients with convulsions from retention, but, once certain that the blood shows the nitrogen metabolism intact, there is no need to spare it. Holst's clinical success confirms the correctness of his premises.

Retroperitoneal Sarcoma.—Bull's case is remarkable not only in the huge size of the myxofibrochondro-sarcoma but in the smooth recovery after its removal. The first symptoms had been slight abdominal pains, ten years before; the tumor became palpable the sixth year. It weighed 15.5 kg., over 34 pounds, after removal. The patient was a machinist, 54 years old.

Isolated Tuberculosis of the Bladder.—Platou relates that there have been sent in for examination, in the last two years, five kidneys removed on account of tuberculosis which proved to be even microscopically free from tuberculosis. The patients' symptoms had indicated tuberculous disease in one kidney and in the bladder, with tubercle bacilli in the urine. Two of the patients seemed to be cured by the nephrectomy; two others died from the progressive bladder tuberculosis; the outcome is not known in the fifth case.

Colorimeter Determination of Nitrogen in Blood and Urine.—Salvesen's research amply confirms the reliability and simplicity of the Folin-Denis methods for determining the total nitrogen, ammonia and urea in the urine, and the non-protein nitrogen in the blood. He considers them superior to other technic, especially for the urine. The reaction is the change in tint after addition of Nessler's reagent. This is prepared with mercuric iodid and potassium iodid with addition of sodium hydroxid.

Infectious Jaundice.—Nicolaysen remarks that epidemic catarrhal infectious jaundice is comparatively common in Norway, but it seems improbable that it has anything to do with spirochetes or Weil's disease.

LIVING PATHOLOGY *

JOHN B. DEAVER, M.D.
PHILADELPHIA

Living pathology is the important contribution of modern surgery to the medical sciences. It is the study of surgical diseases in their various stages of activity, either a return to the normal or the destruction of life, in contrast with dead pathology, which is based on the study of terminal tissue changes after the somatic death of the individual. This study of living pathology, especially in surgical diseases of the abdominal viscera, has banished old misconceptions of their clinical expression, and has given to present day diagnosis a refinement which existed only in our dreams in former days. It has been truly said:

> 'Tis man's worst fault to let the things
> That have been run to waste, and in the
> Unmeaning present sink the past.

The understanding which gives a meaning to present-day surgery has been developed from a knowledge of the faltering steps of scientific progress up to the creation of living pathology. Surgical history may be arbitrarily divided into three epochs. From the dawn of time to the eighteenth century, this ancient art was plied in complete ignorance of the natural processes of disease. While the acumen of observation of our forbears excites our admiration, it does not blind us to the crudity of their empiricism. With the advent of that wonderful transition era, from the darkness of medieval social, economic and moral institutions to the light of modernism, came the emancipation of medicine from the routine and thraldom of authority. To Morgagni, who introduced anatomic and pathologic thinking into medicine, must be accredited honors similar to those accorded the leaders in statesmanship, art, literature and the culture of a marvelous Renaissance. He marks the beginning of the second epoch, the age of dead pathology. The impetus given to clinical medicine by the introduction of pathologic study, together with the continuation of experimental research, begun by Galen to find perfection in Harvey's illustrious work, was such that medicine sought separation from art, its ancient mistress, and became espoused to science, a union that represents the turning point in the development of medicine. Its crowning glory rests with that child of a philosophic mind which the present has christened the living pathology.

The father of this infant prodigy, which in a few years has grown to dominate surgical thought, is Lawson Tait. Observation of diseased processes through the open laparotomy wound enabled Tait to solve the riddle of the so-called broad ligament hematomas, which he discovered were due to extra-uterine pregnancy. In like manner he showed that the numerous infections of the female pelvis were, in the vast majority of instances, secondary to infection of the fallopian tubes, thus supplying the key to what had previously been known only as pelvic cellulitis. As a natural result of Tait's observations it was found that many of these disease processes could be arrested in their trend toward terminal or dead pathology.

John Hunter was undoubtedly the giant intellect of the age of dead pathology, while Lawson Tait merits the honor of having placed living pathology as the foundation of rational surgery. This contribution, together with asepsis and anesthesia, is the Promethean gift of all time to clinical surgery. The leaders in medical science, as in the other sciences, have added luster to their age, not by the elaboration of details, but by the evolution of far-reaching principles, destined to guide practice in many instances through centuries of darkness. This is evident when we recall that ancient medicine was based entirely on philosophic reasoning with its inherent fallacies. With the introduction of experimental medicine and the awakening appreciation of the relative rôles of cause and effect in disease, medicine emerged from behind the dark veil of superstition. For almost two centuries the practice of surgery has been based on knowledge gleaned from the study of clinical symptoms and dead pathology, and the value gained is inestimable. Perhaps two centuries more will elapse before the medical body politic is purged of the false teachings unavoidable in an age so pregnant with colossal truths, but this can neither cast opprobrium on nor dim the luster of an era so wonderful in scientific progress as ours.

When Lister opened the doors of surgical possibility with the golden key of Pasteur's discovery, the new science of living pathology awaited but the master touch of Tait to make it our common possession. Only a few years have passed since then, and "the inaccuracy of thought which may come from a too exclusive devotion to the pathology of the dead" has been displaced in the minds of many by an accuracy born of attention to the pathology of the living. The progressive surgeon of today indulges the hope of that millennium when the symptoms of abdominal disease will create in the mind of every practitioner of medicine the image of living pathology. When that time comes, the phrase of the modern internist may perhaps survive, but only as a curiosity of a dead medical language; the gastro-enterologist, instead of wasting valuable energy and time in the creation of a meaningless terminology, will hasten to the side of the operating surgeon to learn the fundamental truths of living pathologic processes. Teachers of medicine will not indulge

---

*Read before the Tri-State Medical Association, Madison, Wis., August, 1918.

in word-pictures painted in the colors of self-delusion; endowed chairs of internal medicine will demand of the incumbent attendance at the side of the surgeon to observe and confirm the primary pathologic processes in the living. Those of you who come face to face with the difficult problems of abdominal diagnosis will bear a lighter burden if you remember the advice of Moynihan when he says: "I would urge on all those engaged in the practice of medicine the desirability of following their patients to the operating table whenever opportunity occurs. The lessons there to be learned will in practice be of a value beyond all reckoning, and interest in the daily work will thereby be quickened to an unaccustomed degree."

Let us consider the development of knowledge relative to the living pathology of that most frequently diseased abdominal structure, the appendix. The suggestion of Grisolle, in 1837, to open and evacuate abscesses pointing anteriorly in the right iliac fossa, was made in ignorance of the origin of the pus. For centuries the pathology of the dead-house has failed to connect the widespread intra-abdominal lesions, to which death is due in appendicitis, with their origin in infection proceeding from that organ, so insignificant in size and so big in anatomic and physiologic importance.

To the acute mind of Reginald Fitz we owe the arguments which turned the blazing light of living pathology on the right iliac fossa, thus dispelling the mystery and revealing the truth. The cecum was cleared of the odium attached to it by the term typhlitis and perityphlitis. The results of early operation demonstrated the appendix to be the starting point of the inflammation of that region. The bacterial origin of the disease was substantiated. The march of infection in all its stages could be seen and understood. Ulceration, gangrene and perforation of the organ and the involvement of the adjacent peritoneum with spreading peritonitis, or the formation of adhesions with the limitation of the infection and the production of periappendicular abscess; all these processes were easily understood by the opportunity afforded to observe active disease processes, which is living pathology.

Not only were the acute conditions resulting from disease of the appendix cleared up, but the frequency and importance of chronic disease became evident. It is now known that the appendix may be the seat of disease without causing symptoms of sufficient moment to excite attention. It is not at all infrequent to find an appendix to have become thickened, scarred or completely obliterated without any knowledge on the part of the patient that he is harboring a diseased organ. We also now know that a diseased appendix may express itself through some other mouthpiece and become confused with organic disease of the stomach or duodenum or the intestines. By reflex action it may cause spastic contractions of the pylorus, pylorospasm, giving rise to symptoms purely gastric in character; or it may affect the secretion and cause the so-called secretory neuroses. Again the peristalsis and functions of the large or small bowel may be disturbed, also by reflex influences, giving rise to decreased or deficient peristalsis, with constipation, flatulence or diarrhea—so-called intestinal indigestion. This appendicular dyspepsia has been well, though incompletely, defined by Mansell as "a group of symptoms and perhaps signs which point so strongly to organic disease of the stomach or duodenum that it is only by a most careful history or by supervention of definite appendicular symptoms that a correct diagnosis is possible."

Furthermore, disease of other viscera of the abdomen are now with increasing frequency being connected with the functional disturbances due to the presence of chronic appendicitis or to a chronic bacteremia or toxemia induced thereby. It is more than a suspicion that gastric and duodenal ulcer, and inflammatory diseases of the biliary and pancreatic ducts, may often owe their origin to a chronically diseased appendix. Tubal disease and sterility of the female also has been shown to be a consequence of appendicular disease in many cases. Although today the advantage of early operative treatment of acute appendicitis is quite generally recognized, we still frequently enough see the results of neglect in acute appendicitis, which, despite a universal knowledge of the disorder, enables it to retain its distinctive "captaincy in the army of death." In acute lesions of the abdominal viscera, however, opportunities to observe the widespread effects of the disease are rare in comparison with our experience of thirty or even twenty years ago. But the reverse is true with regard to chronic inflammatory processes and the less frequent neoplastic diseases of the appendix.

Rarely a day passes without bringing the surgeon the opportunity, by the operative demonstration of a chronically diseased appendix, to dispel the delusion of a subacute gastric or some fanciful upper abdominal neurosis. These are mistakes of interpretation of the language of the living pathology—mistakes which, I regret to say, frequently condemn the sufferer to chronic invalidism or write his epitaph as a martyr to medical procrastination.

The practical value of a knowledge of living pathology lies not alone in increased accuracy of diagnosis, but also in the recognition of certain limitations of diagnostic possibility. It is beyond the power of man to differentiate, in certain instances, chronic disease of the gallbladder, stomach, duodenum, pancreas and appendix. Living pathology has taught us that disease of one or the other of these organs may, and usually does, destroy their harmony of function, and that clinical symptoms are but discordant notes common to disease processes in all. The gastric symptoms of chronic pancreatic lymphangitis, cholecystic and appendicular disease express their effects on the gastric mucosa by the action of toxins reabsorbed from the diseased area by functional disturbances depending on a common nerve supply. So rarely do we fail to find an organic basis for these digestive troubles that dyspepsia as a clinical entity has practically passed into the oblivion of surgical antiquity. It is true that disturbances in the sensory, secretory and motor functions are not infrequently dependent on systemic disease or more rarely on defects in the mechanism of nervous control, but the entire digestive tract must be studied carefully and systematically before gastric symptoms may be attributed to these causes and be termed "idiopathic," a term which, in the great majority of cases, indicates our inability to interpret the living pathology.

I have sometimes been misled to open the abdomen in the presence of predominating gastric symptoms, only to find the pyloric sphincter to be the seat of spasm of toxic or reflex appendical irritation, as evidenced by the complete relief of symptoms following appendectomy. And on more than one occasion I have opened the stomach in search of the local cause of postprandial pain, hyperchlorhydria or pylorospasm, to find disappointment in the presence of a perfectly healthy mucosa. Even hematemesis has been disproved as a symptom of simple ulceration in a number of instances, and found to depend on the toxic effect on the arterioles of the gastric circulation, or of poisons generated in a distant and diseased organ with the production of simple erosion of the mucous membrane, as described by Dieulafoy. Chronic simple ulcer of the stomach and duodenum is believed by Mayo, Robson and others to result from oral and other septic processes, and recently the frequent association of chronic appendicitis with duodenal ulcer has been explained in the same manner.

It is not my purpose to discourage attempts at differential diagnosis, for this is of the utmost importance and, as a rule, possible; but more intelligent by far is the physician who recognizes the voice common to the living pathology of various structures, than he who attempts to localize the trouble to a particular organ, and then attributes it to functional derangement.

Let us consider the influence of our knowledge of the living pathology of the pancreas and biliary passages on the modern conception of their diseases. Bacteriologic investigation of the contents of the diseased gallbladder has clarified our ideas of the origin of cholecystic disease, and the living pathologist traces, in sequential order, the steps in the progress of the disease from the reception of the micro-organisms through the stages of acute and chronic inflammations and their complications, gallstone formation, precancerous tissue changes and, finally, carcinoma. In 1896, Riedel, in operating in a case of gallstone disease, discovered a chronic pancreatitis, which he differentiated from primary cancer of the head of the organ. Since that time the opportunity for observation which has been afforded by surgery has established the fact that the pancreas is frequently the seat of chronic inflammatory alterations. The touch of the surgeon during life has revealed that which postmortem pathology had overlooked. It has been possible to trace the path of infection from the gallbladder through the lymphatics lying in the right free border of the gastrohepatic omentum to the peripancreatic plexus. The lymph nodes clustering about the pancreas may be seen enlarged, and from their anastomosis with the intrapancreatic lymphatics the assumption is fair that the pancreas is not infrequently infected in this manner. To this early inflammatory disease of the organ the name pancreatic lymphangitis has been applied. That it is a precursor of the more serious and pronounced changes in the pancreas there can be no doubt.

This fact of living pathology has supplied us with the key for treatment of this form of pancreatitis through drainage of the biliary tract. When the source of the lymphatic infection is thus removed, recovery of the pancreas is the rule, as has been demonstrated on occasions when subsequent operation became necessary for some other reason, as well as by the subsidence of symptoms after operation.

The early hope of the surgical relief of diabetes, when this condition is secondary to chronic inflammatory processes in the pancreas, has not been fulfilled. Destruction of the islands of Langerhans by cicatricial contraction of inflammatory tissue bespeaks a process too far advanced for relief by drainage. It denotes a parainfectious condition, the terminal change in the surgical conception of a process that probably would have been amenable to operation at an earlier stage, had the physician in attendance heard in the digestive complaints, not the voice of functional disturbance, but an echo of the cry of distant organic disease.

Obstinate constipation is another field formerly considered exclusively medical and beset with unfounded theories, which are now being subjected to the search of the living pathologist. Sir Arbuthnot Lane, who is most active in this work, has described with great plausibility certain mechanical factors in the form of bands and kinks which embarrass peristalsis and give rise to intestinal stasis. Whether or not we are willing to go all the way with him in his ideas, we must acknowledge that there is truth at the bottom of the well and that it will in the end rise and prevail as a result of demonstrations on the living subject.

That duodenal ulcer is today so frequently observed is exclusively due to the necropsy in vivo. Only a decade ago ulcer of the duodenum was considered a rare lesion and its symptoms were parading under many painful gastro-enterological names, such as hyperchlorhydria, gastralgia, chronic gastritis, etc. Gastric ulcer was thought to be far more common than ulcer of the duodenum. Today the order of frequency is reversed, and a typical syndrome of symptoms has been worked out by means of which the more typical cases may be diagnosed with great accuracy. Still there are many ulcers which give but little evidence of their presence and it is easy to overlook the lesion.

If further illustrations were necessary to prove our contention of the radical difference between living and dead pathology, we need but to contrast the postmortem records of any large hospital with the clinical statistics based on operative findings. Search the records of any pathologic laboratory, and you will rarely find an instance of peritonitis secondary to a perforation of a chronic calloused ulcer of the duodenum. Yet it has been our privilege to operate on fifty-two patients during the past ten years with this alarming complication of ulcer, and we have had fifty recoveries.

As another example, I will mention that instances of death from calculous obstruction of the common bile duct are rare in hospital records. Would not clinical teaching based on records be highly erroneous? The practical significance of the matter is that numerous patients, as a result of these conditions, die outside of the hospital, and that the few are saved by following the advice of an intelligent physician who, cognizant of the living pathology, realizes the necessity of immediate surgical consultation. Furthermore, bacteriologic study, in cases of ruptured gastric and duodenal ulcers, has taught us that during the first twelve hours the peritoneal fluid frequently is sterile, and in this we find the reason for the almost perfect success in early operative interference. This early sterility of the extravasated fluid enables us not only to undertake closure of the perforation, but also plication of the duodenum and posterior gastro-enterostomy as well, procedures that in the great majority of cases relieve the patient of future ulcer trouble and offer an assurance of operative success almost equal to the certainty of death when, after the lapse of a few hours, the peritoneum has become infected. The profound predisposition to cancer of a chronically ulcerated area of the pyloric antrum is one of the startling facts exposed to the light of day by the aseptic scalpel.

Knowledge of the cellular pathology of neoplastic tissue removed at operation has completely rearranged our ideas of cancerous change, and forms the basis of the only rational treatment—early and radical excision of ulcers. The microscopic demonstration of the very earliest malignant changes in the bases of chronic ulcers of the stomach in association with precancerous inflammatory tissue has added the necessity of excision of areas of potential carcinoma. Indeed, this relationship has been so definitely proved that it is the aim of every surgeon whose judgment is based on living pathology to prevent the necessity of radical operations on the uterus, stomach, breast and other organs by the early recognition of malignant degeneration of primary benign tissue changes.

May I venture to call attention to another of the contributions of living pathology toward the saving of human life? This relates to our present knowledge of renal tuberculosis. Formerly, when death occurred from tuberculosis of the kidney, it was the rule for advanced tuberculous processes to be found elsewhere. Very frequently both kidneys were involved and, as a rule, the bladder showed extensive tuberculous ulceration. By the study of renal tuberculosis in motion, several important facts have been apparent: First, that tuberculosis of the bladder is never primary, but always secondary to disease of the upper urinary tract or of the genital tract, and that it most frequently follows infection of the kidney. Second, it has been found that in the beginning surgical tuberculosis of the kidney is usually unilateral. Disregarding the abstract question of whether the infection be distinctly primary or whether it be secondary to tuberculosis of some *other portion* of the body, it is true, at least, that the renal lesion may be the only active focus of tuberculosis in the body. This knowledge has led to nephrectomy for renal tuberculosis, by which many lives have been saved.

We could multiply examples in the citation of various surgical diseases of the abdominal viscera to illustrate the contributions of living pathology to a clearer understanding of conditions which so frequently manifest themselves through the medium of gastric symptoms, but I trust enough has been said to give you a glimpse of the pathway of progress.

Only by standing at the elbow of the surgeon, let me repeat, can the internist hope to attain proficiency in diagnosis and the proper conception of treatment in these conditions. Observe that I say the elbow of the *surgeon*, not the operator, for there is a sharp distinction between the mechanical practitioner of surgery and the true surgeon, who is a specialist, not in operating, but in the field of surgical disease, skilled in diagnosis and prognosis, aware of the dangers and limitations of his art, and as ready to withhold his hand at the bidding of science and conscience as he is bold to attack the condition which, unchecked, threatens the patient's welfare.

A duty, says the poet, is a demand of the hour. The duty of the general practitioner is recognition of the advantages of studying the living pathology and a willingness to employ every means to this attainment. To those whose symptomatic treatment of surgical disease is gilded with the self-delusion of rationality, I would commend that sublime utterance of Polonius:

> This above all: to thine own self be true,
> And it must follow, as the night the day,
> Thou canst not then be false to any man.

ACUTE NEPHRITIS

A STUDY OF FORTY-FIVE CASES

ALBERT VANDER VEER, JR., M.D.
Major, M. C., U. S. Army
NEW YORK
AND
JOSEPH H. SAUNDERS, M.D.
Captain, M. C., U. S. Army
WILLIAMSTON, N. C.

This paper is based on the study of forty-five cases of nephritis occurring on the medical service of base hospital No. 108 at Mesves hospital center, France, during the winter of 1918-1919. About half of the patients were in our own hospital while we were doing routine urine examinations on all patients. With one or two exceptions, none of these men complained symptomatically, and all undoubtedly would have been sent back to duty except for the discovery of albumin, casts and blood in their urine. All cases sent to this hospital were convalescent from some disease or wound and were supposedly on the road to recovery. The other half of our nephritic cases were transferred from other hospitals in this center, and most of them had shown symptoms of nephritis, a few even having had convulsions. Combining the two groups gives us a series of cases varying from the mildest to the most severe.

It was impossible to do any blood-chemical work, or in fact any clinical work except the simplest. We were anxious in our work to determine, if possible, first, the etiology of a nephritis occurring at an age usually free from such a condition, and secondly, the prognosis. Have we any means of determining which cases, if any, will clear up completely, leaving the kidney practically undamaged, and which cases will continue and finally terminate in a chronic nephritis or death? Of course too short a time has elapsed to make any positive statement, and we can only report which cases on discharge showed a urine of good specific gravity, free from albumin, casts and blood, normal blood pressure and no symptoms. We have, however, taken the names and addresses of all these patients, and hope to be able to follow them in the future and determine the ultimate outcome.

ETIOLOGY

Of forty-five cases, eleven gave a history of probable kidney disease in their immediate families. This does not seem to be above the average when we consider how common a condition nephritis is. Dividing the series roughly into two groups, graded as to severity, the first group showing dyspnea, headache, edema and marked urinary findings, the second group showing few or no symptoms except the urinary findings, we found that seven (35 per cent.) out of twenty in group one gave a positive family history, while only four (16 per cent.) of twenty-five in group two were positive. It would thus seem that a patient with a positive family history was a little more apt to develop a severe case than one whose family history was negative.

In taking the past history the following diseases were particularly inquired into: scarlet fever, smallpox, diphtheria, malaria, typhoid fever, pneumonia, pleurisy, tonsillitis, rheumatism and venereal disease. No particular effort was made to determine the history as regards tobacco and alcohol. In a general way it may be said these patients drank very little and smoked a good deal. Of forty-five patients sixteen (35 per cent.) gave a history of tonsillitis, a high percentage, but to be expected when we consider how common a disease tonsillitis is. Twelve (27 per cent.) of these patients gave a history of typhoid fever and this rather surprised us, as it must mean that typhoid is or has been a very common disease in the United States, or else that this group shows an unusually high percentage, and we may consider its occurrence as predisposing in some way to a later nephritis. In this connection another interesting point comes up: All these soldiers had been vaccinated against typhoid. Their urine was examined as they entered the Army, and they then received the vaccine, but their urine may not have been examined again until they were sent to a hospital for some wound or illness. It would be interesting and might prove valuable to examine the urines of a thousand men before and just after receiving their typhoid inoculation, and determine whether there are evidences of kidney irritation which might account for some of the well known symptoms of reaction, and also for this later development of an acute nephritis when an unusual strain is thrown on a slightly damaged kidney.

There were seven cases of rheumatism, four each of malaria, pneumonia and diphtheria, and three each of scarlet fever and smallpox. One patient gave a history of syphilis with a negative Wassermann.

At the suggestion of Lieut. Horace Gray, M. C., who was making a study of similar cases at Vichy, and who kindly came up to Mesves to compare notes and to give us the benefit of his experience, we went into the question of salt and meat consumption. Of forty patients, twenty-four (60 per cent.) said they customarily took more salt than normal persons, and twenty-eight (70 per cent.) ate more meat. Of fifty normals, mostly patients in the same ward, thirteen (26 per cent.) said they thought they ate more salt and meat than was usual. There is therefore a possibility that excessive consumption of salt and meat may have an etiologic bearing on the development of the disease.

RECENT HISTORY

It was our first idea that the immediate cause of admission to the hospital, influenza, pneumonia or gunshot wound, might be the exciting cause of the nephritis in a patient particularly susceptible, but careful questioning brought out the fact that practically all these patients suffered from some symptom, nocturia, dyspnea, headache, or even edema, before the onset of the condition which caused their admission to a hospital. In some of the cases, of course, the patient was admitted for his nephritis and in these no antecedent history of disease could be obtained as a rule. At Lieutenant Gray's suggestion we made a special effort to obtain a history as to the occurrence of diarrhea, and found such a history in fifteen (37.5 per cent.) of forty patients questioned. But it must be born in mind that diarrhea is a very prevalent disease at the front, and the great majority of soldiers have it at some time. Several of our patients stated definitely that they alone of their entire platoon or company escaped without having it, so to our minds diarrhea as an etiologic factor is of doubtful importance. Some of these diarrheas were undoubtedly a streptococcic infection, and theoretically there is no reason to believe that they could not cause a nephritis as easily as a streptococcic throat infection could. Throat cultures of twelve patients gave two positive for streptococcus hemolyticus, not more than one would expect to find in normal individuals.

We were finally compelled to fall back on the hypothesis that the attack was due to exposure to dampness and cold, insufficient nourishment and excessive physical and mental strain, to which the men were occasionally subjected, factors quite foreign to their ordinary civil life.

The earliest symptoms complained of were, as a rule, nocturia and dyspnea. Headache was a rarity and in not a few patients the first thing noticed was edema of the face or feet. A most typical case was that of one of the cooks of our organization, who had been on night work (but otherwise had suffered no hardships at all), and who came in simply because he felt tired and wanted a few days' rest. His urine showed a large amount of albumin, with red blood cells and casts. Tracing some of the histories back, it was surprising to find that some of these men had gone through a month or two of arduous field service while they undoubtedly had their nephritis. Two of the patients had convulsions (both of these cleared up entirely).

PHYSICAL EXAMINATION

This showed diseased tonsils in eleven cases, and pyorrhea or bad teeth in nine. The heart was normal in forty-one cases and normal except for accentuated aortic second sound in four more.

The Wassermann test was negative in forty cases, plus minus in three and one plus in two. None were two plus. Certainly syphilis cannot be considered an etiologic factor. Furthermore, these findings tend to make one disbelieve newspaper tales to the effect that the American Expeditionary Forces are especially subject to venereal disease.

Eye examination revealed the fundus normal in forty cases, with slight changes in two. No case showed any hemorrhages.

Blood pressure was taken on admission and then at intervals varying from one to seven days. Of forty-four patients, nine had a systolic pressure above 160 when it was first taken and thirteen had a diastolic pressure above 90. All of these thirteen cases came in the group of severely ill, and it seemed to us the determination of the diastolic pressure was of the utmost importance in judging the gravity of the condition. In one case in which the patient was bled (in another hospital) the blood pressure fell from 200 systolic and 120 diastolic to 150 systolic and 110 diastolic, with marked improvement in the patient's condition. In not a single case did the blood pressure fail to fall to normal or below after rest in bed and restriction in diet.

At the suggestion of Lieut.-Col. Elliot P. Joslin, M. C., medical consultant of the center, two-hour renal and phenolsulphonephthalein tests were done in all cases and the results are listed in Table 1. The following description of the two-hour renal test and the grading of the phenolsulphonephthalein output is taken from an article by Capt. Warren T. Vaughan, M. C.[1]

Patients were given their ordinary amount of food and liquid at the accustomed time of day, but no fluid was allowed after the evening meal (about 5 p. m.). This restriction was difficult to enforce, and we are not sure the men did not occasionally get some fluid. However, our water was all chlorinated, and the men drank very little of it; nor was water very plentiful, so that we do not think the error here was considerable. Another point to be considered is that the men received coffee two and sometimes three times a day. In a way, these two factors are on opposite sides of the scale and would tend to balance. At the noon meal each man received a teaspoonful of salt, distributed as he pleased. At 7 a. m. on the day of the test each man voided and discarded the urine. Then he voided at 9 a. m. and every two hours up to 7 p. m. The quantity and specific gravity of each of these specimens were determined. The entire night urine from 7 p. m. to 7 a. m. was saved as one specimen, and the quantity and specific gravity were likewise determined. Normally the specific gravity should be at times above 1.018, particularly after meals. With the specific gravity constantly below 1.018 there is present "fixation of specific gravity." There should be some definite variation of urinary volume among the two-hour specimens. The night specimen, including the 9 p. m. and 7 a. m. voidings, should not measure over 400 c.c. in volume, and its specific gravity should be 1.018 or above.

Marked..........	+++	....	.....	3—	5-4	6+	
Maximal.........	++++	....	.....	...	3—	5—	6+

+ means plus or more.

PHENOLSULPHONEPHTHALEIN TEST

One c.c. of phenolsulphonephthalein was injected deep into the lumbar muscles, the patient first having voided urine and drunk two glasses of water. The urine was then voided at the end of one hour and two hours, the amount of phenolsulphonephthalein excreted in each specimen determined, and the results added together. While anything over 50 per cent. is usually considered normal, for the sake of uniformity in comparing with the two-hour renal tests and our clinical grading we have again followed the scheme of Captain Vaughan and considered an output of 0 per cent. to 10 per cent. as ++++; 11 to 24 per cent., +++; 25 to 39 per cent., ++; 40 to 59 per cent., +; and above 60 per cent., 0.

Clinically we graded our cases on admission and on discharge in four classes: (1) those that were normal, or 0; (2) cases showing no symptoms, but a little dyspnea and few urinary findings, or +; (3) cases more marked with dyspnea, edema, high blood pressure, etc., or ++ and +++; and (4) those cases in which there were convulsions, or ++++.

In Table 2 we give the case number, clinical condition on admission, blood pressure on admission, first two-hour renal test, first night test, second two-hour renal and night tests, first and second phenolsulphonephthalein tests and clinical condition on discharge. The first two-hour renal and phenolsulphonephthalein tests were made as soon after admission as possible, and generally within three days, and the second two-hour renal and phenolsulphonephthalein tests were made after from one to three weeks. Theoretically these various tests should correspond to some degree: that is, if the first two-hour renal test shows ++ the first night, the first phenolsulphonephthalein test should be about ++. If the patient improves, the second two-hour renal, night and phenolsulphonephthalein tests should improve to about the same degree, but we find this true in very few of the cases, and in some the discrepancies are marked. For example, in Case 5, clinically + on admission, first two-hour renal ++++; first night ++; second two-hour renal 0; second night +++; phenolsulphonephthalein 0; clinically on discharge 0. Case 7 shows much the same discrepancy. Case 9 shows two normal two-hour renal tests with two night tests of ++ and +++. In Case 13, *the patient*, clinically a severe nephritis on admission and discharge, gave two normal two-hour renal tests and two night tests of +. Both phenolsulphonephthalein tests showed +. Case 41, in which the patient died, gave four normal two-hour renal and night tests, but the phenolsulphonephthalein tests were ++++ and +++.

38	3+	168-116	0	0	+	3+	+	2+	+
39	+	....	0	...	...	...	...	...	+
40	+	100- 70	+	0	0	0	0	0	+
41	3+	160-100	0	0	0	0	4+	2+	Died
42	+	120- 66	0	0	0	0	+	2+	0
43	+	164- 98	0	0	+	+	0	0	0
44	+	126- 56	0	+	0	4+	0	0	0
45	3+	150-100	0	4+	+	3+	0	0	+

Our final conclusion was that, while both tests were of value in prognosis, the phenolsulphonephthalein test is superior for the type of nephritis we were studying, both as regards ease of administration and accuracy. In the latter test the patient has nothing to do, and cannot spoil the result by carelessness or design, while in the two-hour renal test he can make the entire conclusion of no value by disobedience of orders, such as drinking a glass or two of water at night, or by discarding some of the urine which should be saved. It is very probable that the two-hour renal test is of more value in cases of chronic nephritis than in the type of cases we were studying. The phenolsulphonephthalein test we both felt was extremely valuable, and several times it enabled us to give favorable prognoses in cases that clinically appeared almost hopeless. This was particularly true of the patients represented in Cases 3, 22 and 35, all of whom appeared extremely sick on admission, but gave good phenolsulphonephthalein outputs, and eventually were discharged as clinically well. Improvement in the second phenolsulphonephthalein output over the first generally coincided with improvement in clinical appearance.

In general we would say that both tests should always be used and can be used by every practitioner, as they require no complicated apparatus nor laboratory training. An outfit for doing the phenolsulphonephthalein test can be purchased for about $50, and the two-hour renal test requires only a urinometer. In the case of the two-hour renal test great precaution should be taken to follow the rules exactly, as an unintentional slip on the part of the patient may lead to serious error in the interpretation of the results.

TREATMENT

Patients were kept in bed, as far as possible, as long as their urine showed much albumin. They wore flannel pajamas and slept between blankets instead of sheets. One end of a hundred-bed ward was partitioned off and several stoves were put in, an endeavor being made to keep this ward warm and at an even temperature. If a patient's urine cleared up entirely and he seemed well he was transferred to the main ward, put on regular diet and allowed out of bed. A careful check was kept on his urine, and at any sign of recurrence he was put back in the nephritic ward. It may be said here that recurrences were rare, and that once a patient recovered from his attack he seemed to do well.

All patients were put on a quart of lemonade without other food or drink the first day they were in the ward. If they presented edema or marked symptoms this treatment was continued for a further period of twenty-four hours. A few of the patients with high blood pressure or marked dyspnea or edema were bled from 16 to 20 ounces with marked relief. Bowels were, of course, kept freely open.

Diet.—It was possible to have a special-diet nurse for the ward, and as nearly as possible patients were given a salt-free diet. Fluids were restricted to about 1,000 or 1,200 c.c. in the twenty-four hours. No meat was given, but occasionally the patients who were improving rapidly received an egg several times a week, or a little chicken. With eggs at twenty cents apiece they did not enjoy this luxury often.

RESULTS

Most of the patients were transferred before any final result could be definitely determined, as every effort was made, as soon as they could travel, to have them sent home, where they could be treated under better climatic and hospital conditions. The majority of the patients stayed from a month to six weeks, and in that time twenty were discharged as apparently perfectly well, nineteen showed traces of albumin and casts in their urine without any other symptoms or clinical signs, five were improved, but showed quite evidently that they still had a serious kidney condition, and one patient died.

Necropsy on the patient that died, performed by Lieut. Wann Langston, M. C., chief of the laboratory, revealed: Kidneys: Normal in size, dark, mottled, capsule stripped easily, cut surface did not bleed, markings indistinct. Microscopic: Glomerular changes not marked; moderate congestion of intertubular capillaries; cloudy swelling and desquamation of tubular epithelium; edema; intertubular hemorrhages. Diagnosis: Acute diffuse nephritis.

CONCLUSIONS

1. The etiology of this acute nephritis is unknown. It seems to occur more often after typhoid fever, and in people who eat too much salt and meat.
2. The blood pressure was usually not markedly increased, and fell to normal after rest in bed. A high diastolic pressure meant a serious condition.
3. The two-hour renal test was of less value in this particular type of case than the phenolsulphonephthalein test. The latter was of distinct value.
4. Apparently most of these patients will recover completely.
5. We considered the restriction of intake to a quart of lemonade, the bleeding, and the rest in bed on a salt-free diet of great value.

EXPERIENCES IN FRANCE WITH SURGERY OF THE GENITO-URINARY TRACT *

A. RAYMOND STEVENS, M.D.
Assistant Attending Urological Surgeon to Bellevue Hospital; Formerly Major, M. C., U. S. Army
NEW YORK

The object of this paper is not to review the literature nor to attempt any general discussion of how wounds of the urinary tract should be or have been treated. Rather, it is to give a notion of the frequency or the infrequency of gunshot wounds of the urinary tract in war, and to report some personal experiences. These are relatively few in number, yet, supposedly, I was fortunately placed for seeing such work. For well over a year, I was with the British army, as a member of the U. S. Base Hospital No. 2, engaged in general surgery, but was also given the care of all genito-urinary conditions that were admitted to the hospital. (No venereal cases were included, as these were treated in special hospitals in the British army.) Two months were spent operating in British casualty clearing stations (advanced hospitals) during periods of military activity. In September, 1918, I was transferred to an American hospital center, as consultant urologist. This was in accordance with a plan which was formulated in the American Army, to assemble the injuries of the genito-urinary system under the care of urologists, at as early a time as possible.

I was sent first to the Mars-sur-Allier hospital center, then to the center of Mesves. The hospitals at the latter place were all taxed beyond their crisis expansion during the latter months of the war, and the proposed segregation of urologic patients in one hospital of the group could not be carried out during this rush period. The demands of general surgery were obviously of first importance in this crisis, and were so urgent that I could personally follow with any degree of care only such urologic patients as were placed in Base Hospital No. 67, where I was in charge of the surgical service.

---

* Read before the New York Academy of Medicine, March 20, 1919.

INFREQUENCY OF WOUNDS OF URINARY TRACT

I am impressed with two facts concerning war wounds of the urinary tract—the relatively small number of cases in the hospital and the high mortality of these. The relative rarity of kidney and bladder lesions is perhaps explained by the obvious possibility of frequent fatal hemorrhage following wounds of these parts. Various groups of statistics show the kidney involved in from 4 to 9 per cent. of penetrating abdominal wounds, and the bladder in from 4 to 7 per cent. But the number of men with abdominal injuries who live to reach a hospital is only a small fraction of the total number admitted. I have no reliable figures to offer on this point. One American surgeon, in a general operative experience extending over five months in the front area, met with but a single kidney wound, a slight tangential one, and only one of the bladder. Another, whose evacuation hospital work totaled four hundred cases, including a good share of abdominal work, found no wound of either bladder or kidney; and my experience and that of many others were similar.

REPORT OF CASES

In the cases in which I operated at the front, were two gunshot injuries of the lower genito-urinary tract of unusual interest:

The first was a man with machine-gun bullet wounds, the entrance being in the left buttock and the exit in the right wall of the scrotum. In its course, the bullet had completely divided the bulbous urethra, and perforated an old right-sided hernia; this explained the presence of a mass of omentum protruding from the scrotal wall. The cord and testicle were uninjured. The patient had not tried to urinate. Nevertheless it seemed extraordinary that no swelling, induration or ecchymosis was present in the perineum. The urethral lesion was diagnosed by the patient's inability to urinate and my inability to pass a catheter. Operation was performed eight hours after the wound was received. The injured omentum was excised and the hernia repaired. Then, through a perineal incision, an end-to-end suture of the urethra was done, and perineal drainage established proximal to the suture line. The subsequent course was entirely satisfactory up to the fifth day, when the patient was evacuated to the base. As I have heard of two similar cases in which the surgeon felt satisfied with simple drainage of the bladder, I emphasize the importance of immediate suture of urethral injuries, when possible. The results would probably be excellent in many cases, and at the worst the resultant scar would be smaller following suture than would be the case otherwise.

The other soldier referred to also had received a machine-gun wound. The bullet had perforated the posterior muscles of the left thigh and entered the left scrotum. The scrotum was large and edematous, particularly on the right side; a firm elliptical swelling was present in the right inguinal region. No roentgen-ray examination had been made. The general condition was good and no pain was complained of. An injury of the right spermatic cord was diagnosed, and the incision was made over the inguinal swelling. The cord was nearly an inch in diameter. During its dissection, the machine-gun bullet popped out from the depths of the wound and was followed by a gush of blood, which was temporarily stopped by direct pressure. It was then found that the hemorrhage could be perfectly controlled by pressure over both external iliac and femoral vessels, above and below the site of hemorrhage, but not by pressure at either point alone. The incision was extended upward and outward and the external iliac vessels were exposed extraperitoneally. Both artery and vein were found to be nearly severed, and the two ends of both vessels were tied. Following this, the right cord and testicle were removed, and the skin closed with drainage. At the end of thirty-six hours, the general condition was excellent, pulse practically normal, the leg and foot were warm and presented no edema, and the patient was evacuated because of the urgent need of beds.

At the base hospitals, as would be expected, the proportion of urinary wounds was even smaller than in the hospitals of the forward areas. At the Mesves hospital center, early in November, 1918, the number of patients in hospital at one time totaled nearly 23,000. Yet it is worthy of note that I did not see and, in response to direct questions put to the chiefs of all the surgical services, did not learn of a single wound of the kidney at this center.

The only record I have of a case of war wound of the kidney seen before nephrectomy is the following:

The patient, an old English soldier, had received a perforating shell wound, the entrance being in the upper left quadrant of the abdomen and exit to the left of the midline posteriorly. According to the field card, a transfusion of blood had been given at the casualty clearing station and the kidney explored the next day. A hole was found in its cortex, and a fracture of a vert[illegible]ocess noted. The wounds of entrance and exit were [illegible]nd the kidney was drained. No abdominal explorati[illegible]een made. Five days after operation, the man rea[illegible] a very bad condition, with a profuse discharge of [illegible]rough the loin. General supporting treatment and care of the wound were given. Five days later—eleven [illegible] after injury—there was a sudden, severe pain along [illegible]eft costal border, accompanied by great respiratory distres[illegible] vomiting. When seen by the officer of the day, the pa[illegible]t was pulseless. There was slight improvement during [illegible] day, only to be followed by a similar attack which en[illegible] in death. Necropsy disclosed an abdomen filled with blood, the spleen very adherent to surrounding tissues, and a third of it torn nearly free from the rest of the organ. Evidently this rupture had been caused by the original injury; there had been profuse bleeding at the time, and a fresh hemorrhage occurred eleven days later.

The one instance of ureteral injury seen was in a Frenchman, who had been shot in the back above the right costal margin. He came to us classified as a chest injury, but examination showed neither chest nor abdominal signs. Hematuria was the only pathologic finding other than the wound of entrance. Cystoscopy proved the blood to come from the right ureter, but a ureteral catheter passed up to the renal pelvis gave a perfectly clear urine, free from blood. Hematuria continued for some days in decreasing amounts, and finally disappeared. In the absence of any signs of urinary infiltration or ureteral obstruction, no abdominal exploration was performed. However, a machine-gun bullet was discovered by roentgen ray in the bony pelvis and could subsequently be felt through the rectum. It was better located by further radiographic and fluoroscopic examinations, with a roentgen-ray catheter in the ureter, and a palpating finger in the rectum moving the bullet. The removal of this foreign body was easily accomplished through a lateral rectal incision.

MORTALITY OF WOUNDS OF URINARY TRACT

As stated above, in this war the mortality of patients with wounds of the urinary tract has been very high. A recent French publication, giving collected statistics, states that noncomplicated bladder wounds have resulted in a mortality of 56 per cent., and of fifteen cases with coexisting intestinal wounds, only one lived. I have records of eleven patients who reached base hospitals with wounds of or adjoining the bladder, and to my knowledge at least six of them died.

As will be seen from the following reports, not only are intraperitoneal and pelvic complications accountable for the heavy mortality of bladder cases, but wounds in other parts of the body handicap the patient seriously, and materially reduce his chances of recovery.

Of four patients wounded through the perineum, only one recovered. In one of the fatal cases, the urinary fistula, which was demonstrated to come from the bladder, healed promptly after perineal section. But there were other wounds, and later operation was required on an infected knee and on pyemic abscesses of the back and shoulder. Necropsy revealed acute vegetative endocarditis but no infection of the kidneys. Another patient in this group had received a through-and-through wound of one buttock, with comminuted fracture of the sacrum. An extensive débridement had been done at the evacuation hospital. On admission to the base hospital, there was a large tangential wound 8 inches long, with the lower rectal wall fully exposed. Neither feces nor urine leaked from the wound, and there was no further operation done except a revision of the wound with removal of loose fragments of bone. The man died about six weeks after injury. Marked infection of the bladder and ureters and double pyelonephritis were found, but there was no peritonitis.

TREATMENT OF SUPRAPUBIC WOUNDS

Speaking now of suprapubic wounds, I think it advisable, as a rule, to close a bladder wound occurring on the peritoneal surface, but to drain an extraperitoneal opening. A deviation from the latter part of this rule may impair the patient's prospects, as the two following records well illustrate:

One man reached us nine days after being wounded. A bullet had entered the right buttock and had been removed from just under the skin of the right groin. The field card noted that two bladder perforations had been closed by suture and a catheter placed in the urethra and allowed to remain three days. According to the patient, he later voided voluntarily, but the urine had always been bloody after the day of operation. On the train, en route to the base hospital, there was acute retention. The patient arrived in great distress, with his bladder full of blood clots. These were removed by a suprapubic operation under procain. There was found a perforation of the posterior bladder wall in the midline just above the trigone, from which oozed a little blood, not sufficient to require ligature or suture. A suprapubic tube was left in situ for five days, then a urethral retention catheter was employed. Subsequent recovery was uneventful.

The other man referred to had sustained a penetrating machine-gun wound of the abdomen. Two bladder wounds, one intraperitoneal and one extraperitoneal, and a wound of the ileum had been repaired at the evacuation hospital. A urethral retention catheter was tried for four days. In the meantime urine leaked suprapubically; finally the bladder was opened wide. The patient entered the base hospital twelve days after operation with a very dirty, sloughing wound. Special attention was paid to this case in an endeavor to get ahead of the infection, and we were quite at a loss to explain the rapid failure of the patient. Postmortem plastic peritonitis was found, tightly binding together the contents of the lower half of the abdomen; and fully two thirds of the bladder was necrotic.

The importance of removing all loose bits of bone in complicating fractures of the pelvis was especially impressed on us in two instances. The first patient had received a gunshot wound of the bladder, with fracture of the pubic ramus, and other wounds of the right thigh. Suprapubic drainage had been established and bone removed from the bladder at the evacuation hospital. The subsequent history was a long one. The patient was admitted to us in a very weakened state, and continued so to the end. With a retained urethral catheter, the bladder closed in about a week, but marked pyuria persisted. Nothing was gained from a cystoscopy, unsatisfactory because of poor lighting. There was pain only on coughing or on movement of the body in bed, and this was always referred to the pubic bone, the site of the fracture. Abdominal examination was hardly suggestive, and we failed to recognize during the life of the patient the presence of a deep pelvic abscess containing fragments of bone and draining into the bladder.

A parallel case was found a few weeks later. A bullet had entered above the symphysis, and at the forward hospital had been removed from the right buttock by incision. On operation we found an infected hematoma at the right of the bladder and in the space of Retzius. Bits of bone lying free or loosely attached to the pubic ramus were removed. Drainage was established, and convalescence progressed rapidly.

Penetrating buttock wounds are notoriously full of grave possibilities, one of which is a bladder or ureteral injury. However, I recall no such case discovered in the life of the patient, and in none of the several postmortem examinations showing severe pelvic infection was I convinced that this had originated in the urinary tract. Although I saw a number of simple fecal fistulas, I met with no fistula involving both urinary and intestinal tracts. A stricture of the prostatic urethra was found in a man with a fractured pelvis due to crushing, and a number of small wounds of the external genitalia, or healing wounds following orchidectomy performed elsewhere, were seen from time to time.

The bladder complications of gunshot wounds of the spine have interested urologists very much. The behavior of the bladder varies greatly in different instances, but there is usually a period of retention before incontinence sets in; and different devices have been employed to overcome the retention. We had about eighteen or twenty such patients, and tried, in different instances, infrequent catheterization, suprapubic drainage in some persistent cases, and the do-nothing plan so strongly advised by some English surgeons. The last I am convinced is not of universal application, but it is probably the ideal treatment when it can be borne, depending as it does entirely on the overflow drainage of the bladder. Any harm done to the kidneys by a continuously large amount of residual urine in the bladder probably represents a smaller risk than that of urinary infection from repeated catheterization. The rapidity with which infection following catheterization in spinal cases may travel is illustrated by one of our patients, who died twenty-four days after receiving a severe wound of the fifth lumbar and first sacral regions. There was gangrene of the bladder and ureteral mucosa and marked infection of both kidneys.

A number of cases of urinary calculus, perinephritic abscess, genital tuberculosis, torsion of the cord, and a group of less important "civil" conditions were met and treated by operation. The subject of hematuria as found in soldiers was of great interest, and many cases were investigated with the cystoscope. It was amazing that over 90 per cent. of them represented types of what is rather loosely termed "war nephritis." But that discussion will be taken up elsewhere.

40 East Forty-First Street.

EARLY DIAGNOSIS OF ACUTE ILEUS

FREDERICK G. DYAS, M.D. (Chicago)
Major, M. C., U. S. Army
AND
J. N. HALL, M.D. (Denver)
Major, M. C., U. S. Army
CAMP LOGAN, HOUSTON, TEXAS

While the diagnosis of ileus due to strangulated hernia is usually made almost at a glance, there are frequently well developed cases of ileus from bands and kinks, intussusception, volvulus and mesenteric thrombosis which are not easy to recognize in their early stages. The classic signs of abdominal pain, nausea and vomiting, tympany and stoppage of the bowels are frequently lacking, and the medical attendant must make an early decision whether or not laparotomy should be performed.

There frequently is no pathogonomic sign to aid in the diagnosis, and this is especially true of that form of adynamic ileus due to mesenteric thrombosis. In this condition, abdominal distention is the only sign during the early stages. The patient did not complain of pain, because of the absence of the violent peristaltic assaults on the obstructing element, so strikingly demonstrated when the muscular waves are suddenly arrested at the site of a strangulated hernia or intussusception. The whole bowel included in the thrombosed arc is in a state of flaccid paralysis, and is incapable of peristalsis. Distention of the bowel results from the loss of tonus in the intestinal muscles and from the gases generated by the putrefaction of the intestinal contents consequent to the stasis. As time goes on, and the element of peritonitis is added, the condition becomes an abdominal crisis, and there is no hesitancy in advising immediate laparotomy. It is necessary, therefore, to reach an early decision as to operation before the pathologic changes become so developed that a diagnosis is rather forced on the physician than reached as the result of an early appreciation of the morbid sequence. Unlike adynamic ileus, the obstruction resulting from a mechanical obstruction to peristalsis and to the onward passage of the intestinal contents, in the vast majority of cases manifests itself by symptoms corresponding in intensity to the degree of obstruction. The rule is, that in those cases in which the stoppage is instantaneous and complete, the patient suffers violent abdominal pain followed by reflex nausea and vomiting. Abdominal distention follows in a few hours, and in many instances peristaltic waves may be observed, beginning on the left side of the abdomen and coursing toward the right, becoming arrested at the point of obstruction. This sign in itself is pathognomonic.

ILLUSTRATIVE CASES

The following cases illustrate the difficulties of diagnosis in the early stages of these two types of obstruction and the necessity of early operation:

Case 1.—*Mechanical ileus with gangrene of 30 inches of the bowel.*—Lieutenant H., admitted to the Medical Service of Major J. N. Hall, Camp Logan, Houston, Texas, had been operated on about one year previously for suppurative appendicitis, requiring drainage. The laparotomy wound healed by granulation, leaving a long, ragged scar. There was no postoperative hernia, and the patient had not complained of constipation or of abdominal pain subsequent to his operation.

Dec. 21, 1918, he complained of a moderate degree of abdominal pain, but this was not associated with nausea or vomiting, or abdominal distention; however, attempts to move the bowels were unavailing. The patient was removed to the hospital, and an examination at that time detected very little in the way of physical findings, although there was a moderate amount of rigidity in the lower part of the abdomen. There was almost no tenderness, and the pulse and the temperature were normal. It was, therefore, decided on account of the patient's good condition to watch developments until morning. At that time there was marked rigidity and tenderness over the lower abdomen, and no evacuation of the bowels had taken place. Immediate laparotomy was therefore advised and the patient given a general anesthetic.

The old irregular scar was first excised and the peritoneal cavity opened near the middle line in order to avoid, so far as possible, adhesions of the viscera to the under surface of the old scar. When the peritoneum was opened, a large amount of bloody serum drained out. The remainder was mopped up with sponges, revealing a dark mass which at first resembled a large blood clot, but which on being delivered through the wound proved to be a coil of gangrenous ileum. There was a marked putrefactive odor emanating from the wound caused by necrosis of the ileum, resulting from the strangulation of an arc of intestine by a band of strong fibrous adhesions. This segment of bowel measured 30 inches in length and had reached an advanced stage of decomposition. There were areas of grayish pultaceous tissue which were extremely friable; the remainder of the gangrenous loop was black and the vessels thrombosed. A moderate degree of septic peritonitis had been set up by the contamination of the peritoneal surface by the pathogenic flora of the intestinal contents and by the saprophytic organisms of putrefaction. This was evidenced by the blistered appearance of the peritoneum. No cultures of the exudate were made.

Intestinal resection by the suture method was done. The gangrenous arc of intestine, together with a generous strip of sound tissue on each side of the necrotic area, was isolated between intestinal clamps and resected, including the accompanying mesentery. Before removal of the segment of mesentery, it was carefully inspected to make certain that the stumps of bowel to be reunited would be assured of an adequate blood supply.

The anastomosis was made with two rows of silk suture. The method of Connell was employed for the first row and a second supporting line of interrupted sutures for the second stitch. In order to make the union as secure as possible, a piece of omentum of suitable size was amputated, and was sutured around the anastomosis in such a manner as to encircle the bowel at the point of contact of the divided ends. The intestine was then dropped back into the abdomen and the repair of the abdominal wall begun. On account of the large amount of connective tissue incident to the old suppurating wound, it was necessary to dissect out a large amount of scar tissue and to undercut laterally for a considerable distance to obtain normal tissue for the introduction of sutures. Closure was done in layers, leaving room for the introduction of two large rubber drainage tubes, one of which reached down to the lowermost part of the pelvis while the other reached down to the anastomosis. A pint of physiologic sodium chlorid solution was given intravenously while the patient was still on the operating table.

The after-treatment consisted of maintaining the Fowler position, the administration of the continuous drip saline, and morphin to allay peristalsis and pain.

On the third day a low enema was given for the relief of gas pains, and as often as necessary thereafter There was no postoperative nausea and vomiting, and the patient took orange juice and water by mouth on the third day.

This patient developed a small fecal fistula, which healed slowly without any further operative procedures.

Comment.—The mechanical ileus that developed in this case was directly chargeable to the old adhesions that had developed at the site of the former infection.. No attempt had been made to roll out the cut edges of the peritoneum, which frequently cement themselves to the underlying viscera and omentum, even in those cases in which no infection occurs. It is, therefore, the duty of the operator to safeguard his patient so far as possible from the danger of postoperative adhesions, by not permitting the cut edge of the peritoneum to be infolded. This can be easily accomplished by always bringing the needle out on the endothelial surface of the peritoneum.

Case 2.—*Thrombosis of the mesenteric veins, with gangrene of 42 inches of bowel.*—Sergeant H., admitted to the medical service of Major J. N. Hall, Camp Logan, Houston, Texas, Dec. 16, 1918, had felt in his usual good health and had gone to town on a pass. He ate a large amount of peanuts in addition to a hearty meal, and the next morning complained of not feeling well and would eat no breakfast. A few hours later he was seized with acute abdominal pain, nausea and vomiting, and tenderness over the whole abdomen. Attempts to move the bowels by cathartics and enemas were unavailing, and tympany became marked. There was no elevation of the pulse or the temperature, and the physical examination of the chest was negative. The abdomen resembled that of a man suffering from retention of urine, as there was a tumor occupying the lower portion of the abdomen corresponding in size and shape to the overdistended bladder. The patient stated, however, that he had no difficulty in voiding urine; but, in order to confirm this, the bladder was catheterized and only a few drops of urine were recovered. It was thought possible that there might be an abscess of the abdominal wall with a resulting reflex ileus. Immediate operation was advised because, while it was impossible to make an accurate anatomic diagnosis on the basis of the underlying pathologic condition, it was impossible to escape the conviction that the man was suffering from ileus, either of the mechanical, dynamic or adynamic type. The tumor assumed the shape and size of the mass sometimes observed in the condition described under the term "ileus duplex," in which several coils of ileum are pasted together and lie with the ruptured appendix in the true pelvis.

This tumor, if appearing in a woman, would almost surely result in the diagnosis of uterine fibroid, before the bimanual examination was made.

Under general ether anesthesia a right rectus incision was made in order to give the most liberal exposure of the abdominal contents. The possibility of an abscess of the abdomiinal wall was kept in mind while going through the tissues, but no collection of pus was found. When the peritoneal cavity was opened, a considerable amount of bloody serum was found. There was an odor of putrefaction which was explained by the exposure of a large amount of gangrenous bowel. This was carefully lifted out until normal intestine was met, both proximally and distally. The gangrenous arc constituted 42 inches of the ileum and was consequent on a thrombosis of the mesenteric veins draining that segment. No other pathologic condition was noted to account for the mesenteric thrombosis.

It was considered doubtful whether operation was warranted because of the great amount of tissue involved, but on account of the patient's good general condition, it was felt that resection was justified.

The gangrenous arc was isolated with the intestinal clamps applied well into healthy tissue, and an end-to-end anastomosis was made by the suture method. Two large drainage tubes of rubber were inserted, one down to the site of the anastomosis, and the other down to the most dependent portion of the pelvis. One pint of physiologic sodium chlorid solution was given intravenously during the course of the operation, and the patient was returned to bed with a good pulse.

He was immedately placed in the Fowler position on the Gatch frame, and hypodermoclysis was begun with physiologic sodium chlorid solution by the drip method. The patient experienced no postoperative nausea nor vomiting, and there was but little abdominal distress. The bowels moved on the second day with the aid of an enema, and thereafter once or twice daily until convalescence was well established. There was a considerable amount of drainage of serum through the tubes, the first of which was removed on the fourth day, and the second on the eighth day. The rectal salines were discontinued on the fifth day, but the Fowler position was maintained for ten days. The highest point reached by the temperature was 100, and by the pulse, 120.

The abdominal wound healed by primary intention, except at the point at which the tubes were introduced; this healed by granulation, but there was no tendency to hernia. The patient returned to duty, Jan. 24, 1919.

Comment.—This case emphasizes the vast importance of making an early diagnosis of pathologic changes within the abdomen requiring immediate operation, and subjecting the patient to operation without delay, even though the precise anatomic and pathologic lesion cannot be recognized before entering the peritoneal cavity.

POLLEN EXTRACTS AND BACTERIAL VACCINES IN HAY-FEVER

SECOND REPORT

IRA FRANK, M.D.
AND
SOLOMON STROUSE, M.D.
CHICAGO

In March, 1916,[1] we published our first report on the treatment of hay-fever by injections of specific antigens. We analyzed the literature and our own clinical experience for results in the treatment of hay-fever patients with pollen extracts alone, and with bacterial vaccines alone, and we concluded that neither method had given completely satisfactory therapeutic results. We suggested the theory that hay-fever symptoms could be explained by the conception of the disease as a combined state of hypersensitiveness to various pollens and a condition of nasal infection, or, as called by Adami,[2] "subinfection." There can be no doubt that each hay-fever patient represents a state of hypersensitiveness to a definite pollen, as can easily be proved by ocular or dermal tests with pollen extracts; but there are at least theoretical considerations indicating the presence of a complicating infection. Furthermore, because of the inconclusive results of pollen therapy and because bacterial vaccine therapy showed as good or better results than pollen therapy, it was concluded that the logical treatment of the disease would be by a combination of the two methods.

Up to that time our results had shown that approximately 64 per cent. of the patients receiving bacterial vaccines had been relieved in greater or less degree of their symptoms, and that 70 per cent. of those receiving pollen extract alone were relieved. In neither series, however, did we feel that we had reached the best possible therapeutic result. We reported, likewise, on four patients who had received pollen extract prophylactically in increasing doses during the 1915 season, and who, despite the injections, suffered during the hot spell in September from very severe attacks. All four of these patients were immediately treated with autogenous vaccines in large doses. The results in these four cases were, indeed, surprising; for after the first injection there was an almost complete disappearance of symptoms. In all four cases vaccine therapy was continued until the end of the season with unquestionable seasonal cures. The patients went through the remainder of that summer without any symptoms of hay-fever, although they had been sufferers for many years. From our experience we did not attempt to draw large conclusions, but merely suggested that our results warranted a continuation of efforts to prove or disprove the theory advanced and to apply the therapeutic principles to a larger number of cases.

[2] Adami, J. G.: Brit. M. J. **1**: 177, 1914.

In our report we called attention to the fact that bacterial vaccines had previously been used in the therapy of the disease. The reports up to the time of our first publication were incidental and fragmentary. After the publication of our article several reports were made by other investigators on the combined method of treatment, the most important of which indicated favorable results. Medalia[3] believed from his experience that the pollen extract could be dispensed with in favor of bacterial vaccines. Scheppegrell,[4] without mentioning work of previous investigators, concluded that the most desirable method of treatment was a prophylactic injection of pollen extract followed, at the height of the season, by bacterial vaccines.

Our own work was continued during the season of 1916, but we did not employ exactly the same method of injection as we had employed in the previous year. The sensitization tests that we had freely used from 1913 to 1915 had shown that all of the autumnal catarrhs met with in the Chicago district were caused by ragweed pollen. Therefore, we had grown for us in a neighboring hothouse a large amount of ragweed, which pollinated early and gave us a plentiful supply of ragweed pollen for early injection. The extract was made and the dilutions employed according to the method of Koessler.[5] During the season of 1916 sensitization tests were dispensed with because of our previous experience. Likewise, we did not control dosage by means of the quantitative skin reaction, because, as stated in our first article, it seemed proved that clinical results did not at all parallel the results of the dermal tests. Theoretically, one might expect such a state of affairs to exist exactly as occurs in typhoid fever when, as is well known, clinical immunity bears no quantitative relationship to the strength of agglutinins or bacteriolysins in the blood stream; Goodale[6] is of the same opinion. Using as a pollen unit a dosage equivalent to 0.0000001 gm. of pollen, we usually began treatment with an injection of 10 pollen units, increasing by various multiples, depending on the reaction of the patient. The accompanying tables give the details of the complete injections for a number of patients.

During the season of 1916 we attempted to investigate three points concerning which exact data were lacking: first, whether better results would accrue from combining in the prophylactic injections beginning in June or July both the pollen extract and the bacterial vaccine; second, the size of the dose of pollen extract; and, third, the relative value of autogenous vaccines as compared with stock vaccines. Concerning this last point it will be recalled that at the time of our first publication considerable attention was being paid to the question of nonspecific protein reactions, and the suggestion had been made to us that the results of our treatment in 1915 had not been due to the formation of specific antibodies, but had been due to a nonspecific protein reaction. If the results were due to a nonspecific reaction, then the theory underlying our treatment was incorrect. Therefore, in many cases, in 1916, we used a stock vaccine of *Staphylococcus albus* made from the nasal mucosa of one of the patients who, in the previous year, had been successfully treated.

TABLE 1.—PROTOCOL OF TREATMENT GIVEN MRS. F (CASE 1)

Date	No. Pollen Units	Dose
July 8	10	
July 12	20	plus .1 ccm. stock vaccine (equal to 50 million Staphylococcus albus)
July 15	50	plus .15 ccm. stock vaccine
July 19	150	plus .2 ccm. stock vaccine
July 22	350	plus .3 ccm. stock vaccine
July 26	500	plus .3 ccm. stock vaccine
July 29	700	plus .4 ccm. stock vaccine
Aug. 2	1000	plus .5 ccm. stock vaccine
Aug. 5	1500	plus .6 ccm. stock vaccine
Aug. 8	2000	plus .7 ccm. stock vaccine
Aug. 12	2000	plus .8 ccm. stock vaccine
Aug. 16	2500	plus .9 ccm. stock vaccine
Aug. 21	2500	plus 1.0 ccm. stock vaccine
Aug. 28	3000	plus 1.0 ccm. stock vaccine

There was considerable variation of opinion regarding dosage of pollen extract, and it seemed to us that the only possible solution of this problem lay in the therapeutic test. In some cases then our dosage ran as high as 3,000 pollen units. Furthermore, no data were available on the best method of injection, so we decided to try the combined prophylactic on a comparatively large percentage of our patients.

These three factors which entered into the treatment during the season of 1916 complicated considerably the interpretation of results as compared with previous years. A further complicating element was the excessive heat during the summer and the corresponding unusual severity of the hay-fever season. In 1916 patients who in previous years had been free from hay-fever symptoms in certain districts of Michigan and in the mountains of the East complained of symptoms in the supposedly hay-fever-free resorts.

TABLE 2.—PROTOCOL OF TREATMENT GIVEN MISS E. (CASE 2)

Date	No. Pollen Units	Dose
July 7	10	
July 12	20	
July 15	40	
July 18	80	
July 21	150	
July 25	300	
July 28	600	
Aug. 1	1000	
Aug. 4	1500	
Aug. 8		.1 ccm. stock vaccine
Aug. 11	2000	plus 2. ccm. stock vaccine
Aug. 15	2000	.3 ccm. stock vaccine
Aug. 21		.3 ccm. stock vaccine (hay-fever symptoms)
Aug. 28		.4 ccm. stock vaccine
Sept. 6		.5 ccm. stock vaccine

It was, therefore, difficult to interpret the results of injection therapy in the thirty patients treated. Of eleven patients treated by the combined injections from the early part of July through the hay-fever season, benefit of varying degree is noted in five, and in only one could the result be considered a seasonal cure. The treatment of these patients was practically identical and will be illustrated in Table 1, the protocol of a patient who received much benefit.

Although this patient showed some apparent good results from the treatment, in no others receiving the same method of treatment were results comparably good. The protocol might just as well have been from one of the patients who was not at all benefited. The impression gained from this series, when compared with other cases treated the same year, is not good. Ten more patients were treated by prophylactic injections of ragweed pollen, followed at the beginning of the hay-fever season by the combination of vaccines and pollen extracts, or in some cases by bacterial vaccines alone. A protocol of one such patient who was markedly benefited is given in Table 2. Another patient treated similarly, who was able for the first time in years to remain in town, is given in Table 3. Both of the last two patients had been hay-fever sufferers for years and had received treatment with pollen extract or bacterial vaccines in the two preceding years. The protocols of the patients who showed no results from treatment cannot be differentiated from the two just given.

Aug. 25	Better	.1 ccm. (100 million S. albus autogenous)
Aug. 29		.25 ccm. autogenous vaccine (miserable attack)
Sept. 1		.2 ccm. autogenous vaccine (absolutely no relief)

Three patients were treated by increasing doses of bacterial vaccines alone during the course of the attack, two of whom showed some relief and one a seasonal cure. In contrast to these three are six patients given combined pollen extract and bacterial vaccines during the attacks. Of these six, four showed absolutely no effect, none was cured, and two moderately relieved. Case 4 (Mr. C.), with no treatment in 1914 and 1915, with the onset about August 15, was treated according to the protocol given in Table 4.

TABLE 5.—PROTOCOL OF TREATMENT GIVEN DR. C. (CASE 5)

Date	No. Pollen Units	Dose
July 13	2	
July 17	3	
July 19	5	
July 23	10	
July 26	30	
July 30	70	
Aug. 2	100

Aug. 9	500	
Aug. 13	700	
Aug. 16	1000	
Aug. 19		100 million Streptococcus albus, autogenous
Aug. 23		200 million Streptococcus albus, autogenous
Aug. 26		300 million Streptococcus albus, autogenous
Aug. 30		400 million Streptococcus albus, autogenous

Summarizing the results in 1916, we find there was some benefit in a little more than half of the patients treated. Nothing like the startling results of the previous year was obtained. Perhaps the most important lesson was the negative value of some of the procedures. From the work this year it seemed unwise, first, to use such large doses of pollen extract; second, to carry the pollen extract injections through the period of hay-fever attacks; third, to combine the pollen and the bacterial vaccines in prophylactic injections, and, fourth, to use stock vaccines.

We were unable to continue our work in 1917, owing to uncontrollable circumstances, and in 1918 war conditions prevented a resumption on the scale hoped for. However, the 1918 results are interesting and valuable enough to include in this report. We treated only sixteen patients, and they were all treated in practically the same manner. We used this year one of the commercial pollen extracts (ragweed), started injections in July and continued to the height of the season, when autogenous vaccines were made and intensively injected. The protocol of one case given in Table 5 is practically the story of all.

All but two of the patients treated in this manner remained in Chicago throughout the hay-fever season in considerable comfort, and all felt that the relief from suffering was remarkably good. The two patients who went away before bacterial vaccines were started suffered rather intensely from hay-fever in a supposedly hay-fever-free section of Michigan. The results this year compared favorably with those of the 1915 season.

CONCLUSIONS

1. Specific therapy should not be undertaken in the presence of pathologic conditions in the nose or accessory sinuses. It has not been our experience that removal of polyps or similar operations has cured hay-fever patients, but it has been our experience that such operations may be necessary if subsequent therapy is to be successful.

2. In a disease with the remarkable seasonal variations of hay-fever, it would be folly to attempt to draw definite or final conclusions from the work so far reported; but from the consideration of our own and reported results, we believe it is fair to say that the method of treating hay-fever patients by early prophylactic injections of pollen extract, combined with late and intensive injections of autogenous bacterial vaccines, offers the greatest therapeutic promise of any method so far advanced in the treatment of this disease. Pollen extracts alone and bacterial vaccines alone, while giving results, do not seem to relieve so many patients as does the combined therapy. Treatment with pollen extract should start early in the season (June or July) and should be discontinued at the height of symptoms, at which time bacterial vaccines should be substituted.

3. We have not found that injections one year have prevented attacks the succeeding year, but we do note that in patients receiving continued treatment from year to year there is a definite tendency for the hay-fever symptoms to become progressively less severe.

104 South Michigan Avenue.

State Responsibility for Public Health.—The state, like the federal government, has at least three responsibilities in the field of public health—the prevention of the introduction of disease from without, the control of the intercounty, or intermunicipal spread of disease, and the health of all the people within the state from the general welfare point of view. These responsibilities can be met only by some degree of state control over local health conditions. This control should be more than advisory and should be applicable at all times and places and when and where there is a menace to other localities.—B. S. Warren, M.D., *Public Health Reports.*

over half of these were between 18 and 20. While these figures must not be accepted as absolutely correct, because of the common tendency among such women to falsify their ages, it is nevertheless believed that the errors tend to correct themselves, and that these are the ages at which most women of ill fame "ply their trade." It is in these years that the economic pinch and the temptation for wrong doing seem to be strongest. Society must place greater safeguards about the girls of these ages, and educative measures should be enforced in the training of the girl following adolescence.

Table 2 and Chart 2 show the distribution of the 126 cases according to the mental age on the Binet-Simon (Goddard) scale. From this it can be seen that 15.9 per cent. of the women had a mental age of less than 10 years, and that 53 per cent. had a mental age of 10 or under. In other words, only 47 per cent. can be said to have had average mental ability or above. Even if we grant that the average intelligence of persons of the negro race is two years below that of persons of the white race, the generally accepted figure, it is evident that women of deficient mentality of both races form about one half of the women arrested here for sexual offenses. If those of normal intelligence who are psychoneurotic, addicted to drugs, or otherwise abnormal are added to this group, the ratio of defectives is materially increased.

TABLE 2.—DISTRIBUTION OF 126 WOMEN ACCORDING TO THEIR MENTAL AGE

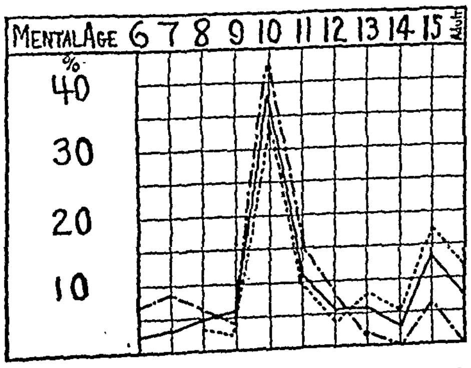

Fig. 2.—Distribution of 126 cases according to mental age.

Our percentage of 53 at the mental age of 10 or under agrees closely with the 51 per cent. "feeble - minded" reported by the Massachusetts Commission for the Investigation of the White Slave Traffic in its examination of prostitutes. Yet so many of the women examined in Newport News presented border-line cases that it is safe to say that hardly more than 10 per cent. of those examined here could under present laws be remanded to institutional care because of feeblemindedness. Thirty-eight per cent. of our cases fall in year 10 of the scale. This situation constitutes a great problem in the disposition of these cases. These women are mentally inferior, almost all of them being high-grade morons, yet they are almost entirely self-supporting members of society or capable of being such, aside from any commercial prostitution that they may carry on, and the suggestion of their confinement to institutions for the feebleminded would raise many serious objections. Their appearance is generally so good and their bearing so self-confident that the layman, and even the judge before whom they appear, would hardly suspect the deficiency which is probably largely responsible for their delinquency. Even should the average judge be told of their deficiency, it is probable that he would greatly discount it. Colonization of mentally defective prostitutes under conditions which would permit them to continue supporting themselves by industrial occupation under a fairly normal environment is probably the eventual solution of the problem.

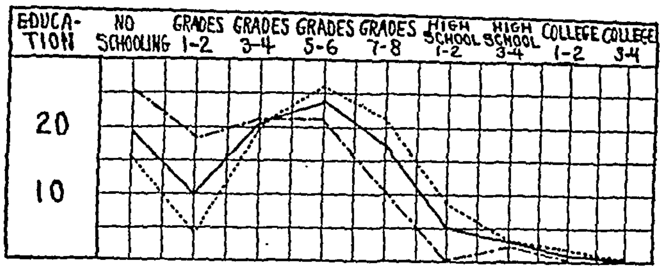

Fig. 3.—Distribution of 113 cases according to grade reached in school.

Comparison of the 53 per cent. mental deficiency at Newport News with similar data from other places is interesting. Sen.-Surg. J. O. Cobb[1] of the U. S. Public Health Service quotes the following percentages of "feebleminded" or mentally deficient:

	Per Cent.
Massachusetts commission for the investigation of the white slave traffic	51
Chicago Morals Court	62
Chicago Morals Court (126 definite prostitutes)	85.8
Illinois Training Schools for Girls (sexually immoral girls)	97
Massachusetts Reformatory for Women	49
Bedford State Reformatory	29.8
New York Probation and Protective Association (500 delinquents)	37
New York Probation and Protective Association (111 prostitutes)	35
Virginia Board of Charities and Correction (definitely determined commercial prostitutes in segregated district)	71.6

It is interesting to note that our figure approaches very closely the average of the above cases. It is to be remembered that the higher percentages quoted above are primarily from institutions which tabulated definitely established cases of delinquency and prostitution, often of the hardened, strictly commercial type, thus representing a specially selected group, whereas our cases are not largely commercialized vice, but rather sexual delinquents and venereals who are not old offenders.

Recent investigation in the state of Michigan by Katherine Ostrander[2] also emphasizes the menace of the feebleminded prostitute and quotes some interesting figures. Sixty women from 385 acknowledged or unacknowledged prostitutes, admitted to hospitals for venereal treatment, were found to be mentally retarded,

---

1. Cobb, J. O.: New York M. J., Nov. 2, 1918.
2. Social Hygiene Monthly, October, 1918.

but not to a degree making necessary institutional care on that account. In psychopathic clinics established in Detroit and a few other cities, out of 247 women examined, forty-five (18 per cent.) were pronounced totally feebleminded and unable to adapt themselves to society; those feebleminded and psychopathic not to a degree demanding institutional care amounted to 35 per cent. of the whole, totaling 53 per cent. mentally defective, which is closely comparable to our data at Newport News.

These figures add evidence to the already well-established belief that virtually half of the country's prostitutes are mentally deficient or feebleminded. It is highly important, as data of this sort accumulates, for the country at large to realize that legislation must be enacted in the several states which shall hold in restraint the prostitution of the large group of high-grade morons who to the uninitiated appear to be perfectly normal and often unusually attractive physically.

The apparently great increase of cases of those at the mental age of 15, as shown by Table 2 and Chart 2, has no significance, since the old Binet-Simon (Goddard revision) scale stops at the year 15; a number of cases of this grade might have rated adult, which on a newer scale like the Stanford-Binet, used in the Army, might mean a normal distribution over the years from 16 to 18.

Eighteen women showed evidence of mental unbalance. Of these, nine measured mentally 15 years or over on the scale. Eleven were emotionally unstable, three epileptic, one a drug addict, and two probably had dementia praecox. The examinations were made on the day of the arrest or the first day following, so there were few opportunities to uncover such deviations from the normal. By all chances the numbers given above are greatly understated.

Chart 3 and Table 3 give the distribution of 113 cases according to the extent of schooling. It is significant that almost 20 per cent. of these women (25 per cent. colored and 15 per cent. white) were without schooling and were illiterate. This figure is in excess of Virginia's percentage of illiteracy as quoted in the U. S. Census of 1910, which showed that fifteen in every hundred persons in this state were illiterate.

TABLE 3.—DISTRIBUTION OF 113 WOMEN ACCORDING TO GRADE REACHED IN SCHOOL

Grade Reached in School	Number Reaching Grade	Per Cent. Reaching Grade	Number White	Per Cent. White	Number Colored	Per Cent. Colored
No schooling..	22	19.5	11	15.7	11	25.5
Grades 1-2....	11	9.7	3	4.3	8	18.6
Grades 3-4....	23	20.4	14	20.0	9	21.0
Grades 5-6....	27	23.9	18	25.7	9	21.0
Grades 7-8....	20	17.7	15	21.4	5	11.6
Grades in high school, 1-2..	6	5.3	6	8.6	0	....
3-4..	3	2.7	2	2.9	1	2.3
Years in college 1-2..........	1	0.8	1	1.4	0	....
3-4...... ...	0	....	0	....	0	....
Totals ...	113	100.0	70	100.0	43	100.0

It will be noted that 30 per cent. of the group did not go to school beyond the fourth grade. Adding to this the illiterates who did not go to school or who had less than one year's schooling, we find the number becomes 50 per cent. who did not reach the fifth grade. Many factors, no doubt, enter into the cause of so large a percentage leaving school so early or never having attended school, such as economic necessity, poor schools and low intelligence. The ignorance of these prostitutes is appalling.

Such are the facts. Public sentiment should create the solution of the problem. All that the investigator can do is to determine the facts of the case and present them to the public; the public acting on this knowledge should create the sentiment among its legislators and judiciary that will bring about the purging of society of the social disease, just as quarantine is enforced in any contagious disease.

SUMMARY

Summing up, we find these to be the outstanding facts in the mental aspects of prostitution as found in Newport News:

1. Fifty-three per cent. of the women arrested for prostitution and kindred offenses and held in the detention home for examination had a mental age of 10 or under.
2. In addition, 15 per cent. of those who were not mentally deficient showed mental disorder.
3. Ten per cent. were so deficient as to warrant, under existing laws, segregation in an institution for feebleminded.
4. Fifty per cent. of these women did not reach the fifth grade in school.
5. If we are seeking for a "type," we might say that the composite of the delinquent woman as found in Newport News would seem to be a woman of 19, slightly mentally deficient, with schooling to the fourth grade.

BACK PAIN IN THE MILITARY SERVICE *

WALTER A. SHERWOOD, M.D. (Brooklyn)
Lieut.-Col., M. C., U. S. Army; Chief of the Surgical Service, U. S. Army General Hospital No. 1

AND

MERRITT L. JONES, M.D. (Wausau, Wis.)
Captain, M. C., U. S. Army; Orthopedic Surgeon, U. S. Army General Hospital No. 1

NEW YORK

Cases of pain in the back as seen in the military service may, for purposes of convenience, be grouped under the following headings:

- I. Referred pain:
  - A. Aneurysm and mediastinal growths.
  - B. Gallbladder disease, gastric ulcer, etc.
  - C. Kidney infections, renal and ureteral calculi and other genitourinary affections.
  - D. Static back.
  - E. Prominent abdomen due to deficient musculature, excessive fat, enteroptosis, etc.
- II. Functional pain.
  - A. Hysteria, malingering, the neuroses and allied conditions.
- III. Essential back pain (acute and chronic):
  - A. Traumatisms and acute infections.
    - 1. Sprains, strains, fractures and dislocations.
    - 2. Perinephritic abscess.
  - B. Sacroiliac conditions.
    - 1. Infections.
    - 2. Misplacement.
  - C. Sacralization of fifth lumbar vertebra.
  - D. Infectious conditions.
    - 1. Rheumatoid, closely allied to the arthritides in which focal infections may be the cause.
    - 2. Typhoid.
    - 3. Tuberculosis.
    - 4. Syphilis.
    - 5. Gonorrhea.
    - 6. Spondylitis deformans, osteo-arthritis, etc.

---

* From the Surgical Service, U. S. Army General Hospital No. 1.

E. Congenital malformations.
F. Curvatures.
  1. End-results of infections.
  2. Rickets.
  3. Postural curves, deficient musculature, etc.
C. New growths.
  1. Carcinoma.
  2. Sarcoma.
  3. Osteoma, etc.

Although such a classification may be incomplete, it nevertheless serves as a guide and working basis in the majority of cases and it seems appropriate to discuss briefly these various groups in order to point out the more essential features with reference to their recognition, proper management and military disposition.

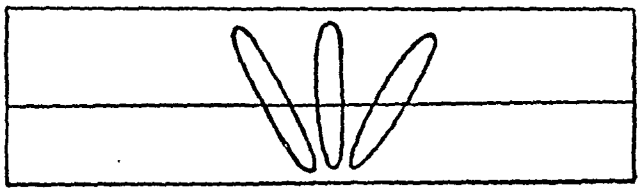

Fig. 1.—Method of strapping patients.

REFERRED PAIN

Back pain caused by aneurysm and mediastinal growths, together with the referred pain of gallbladder disease, gastric ulcer and affections of the kidney, has been exceedingly rare in our experience and needs but brief mention. In the series seen at this hospital only one case could properly be classified in this group. The diagnosis was glomerular nephritis and the principal symptom was a dull pain in the lumbar region. After a most painstaking study of this patient no other cause of back pain was revealed and it was finally classified as renal in origin.

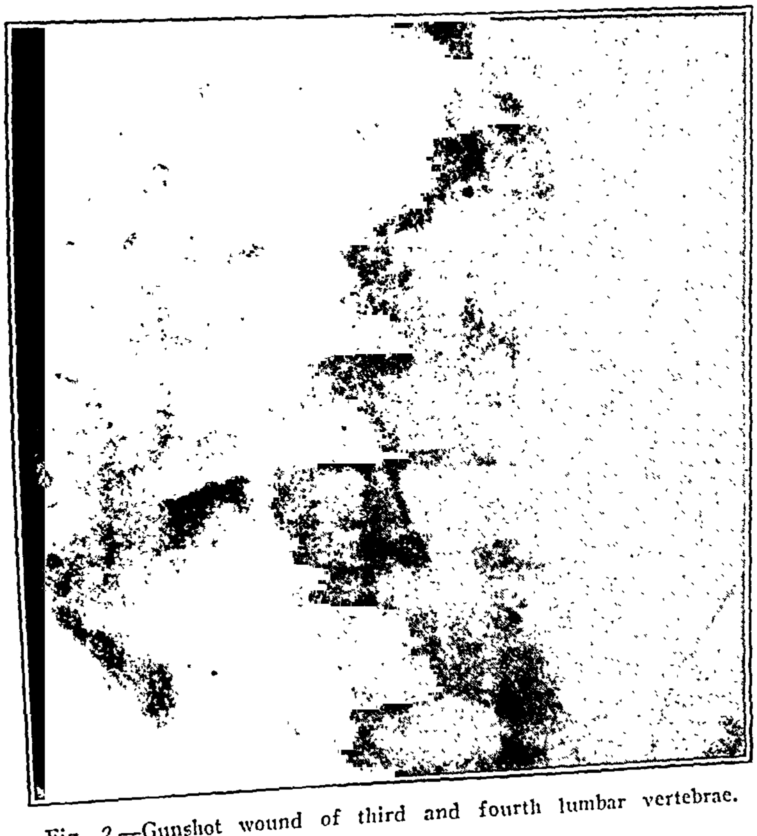

Fig. 2.—Gunshot wound of third and fourth lumbar vertebrae.

The condition commonly described as "static back" has been found to be relatively common. In our experience it was frequently observed in the younger troops from the southern states. Such soldiers are prone to be underdeveloped with poor flabby musculature. They are, as a class, tall, thin and typically enteroptotic. The spine itself shows few signs of any pathologic condition other than a moderate amount of lordosis. Many of these men are also the subjects of second or third degree flatfoot.

TREATMENT

In treating these cases our main purpose was directed toward general physical betterment. In addition to the usual hygienic and tonic treatment, plus the correction of any existing foot trouble, we found that carefully graduated remedial exercises were most beneficial in this class of patients. If the old anatomic teaching is accepted that the cervical fascia is connected with the pericardium and the latter with the diaphragm and that the raising of the diaphragm causes the abdominal wall to retract inward, then we may form a rational basis for and a proper understanding of remedial exercises and it is possible to appreciate the importance of chin up, chest out and belly in. We have placed our patients in this class in the general remedial detachment in which graduated exercises are undertaken under proper supervision. As a group they have shown marked improvement within a few weeks after exercises were begun and many of them were returned to full duty free from their former complaints. In a few cases a simple body support has been helpful in relieving the back pain.

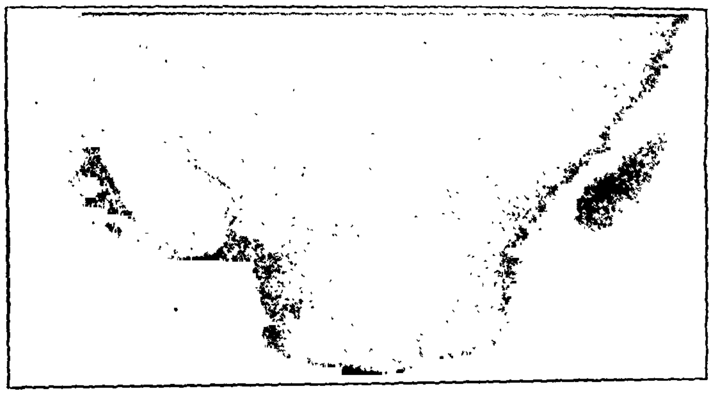

Fig. 3.—Sacro-iliac slip as evidenced by alteration and separation of the symphysis pubis.

FUNCTIONAL PAIN

Pain in the back is a frequent occurrence in diseases of the prostate, bladder, seminal vesicles and in some cases of varicocele. A complete venereal history together with a thorough genito-urinary and rectal examination, has become a routine practice in all cases of back pain seen at this hospital.

Malingerers frequently complain of pain in the back. We have seen several who claimed to have dull aching pain in the lower lumbar region. They simulate many of the common organic conditions and require the most careful observation and scrutiny before the real nature of the trouble becomes evident. Sacro-iliac disease is most often simulated.

Closely allied to this group of malingerers but distinct from it are the cases of hysteria and the various neuroses. Such cases, however, almost invariably show the typical stigmata that accompany such conditions and are relatively easy to diagnose.

We have seen all degrees of curvature associated with a simple hysteria or neurosis. A striking case was that of a soldier flexed almost to a right angle at the hips and who could walk only with the aid of crutches. This man promptly cleared up after the administration of a general anesthetic and the application of a plaster casing from the nipple line to the ankles. Another patient had a supposed shortening of 2 inches in his left leg. After careful examination this was found to be due to a tilting of the pelvis, hysterical in origin. Many of these patients can be promptly relieved of their troubles. Most often, however, they belong to the group of psychoneurotics, with hysterical manifestations, and are fit only for domestic service, for the reason that under stress of active warfare and its accompanying hardships, they break down with other nervous manifestations and become a burden to the government.

ESSENTIAL BACK PAIN

The various cases of traumatism are too numerous for a detailed description. They vary from simple muscular strain to marked cord lesions associated with paralysis. We have already begun to receive and care for the gunshot wounds of the spine which will soon be so common in the military hospitals of this country.

It has been surprising also to notice the frequency with which slight rotations and dislocations of the vertebrae have been revealed by careful roentgenographic examination—defects which apparently account for the disability of which the soldier complains. Most of these belong in the group of spondylolisthesis cases described by Killian and Neugebauer. The exact etiology is often obscure but in most cases it may be traced to direct traumatism.

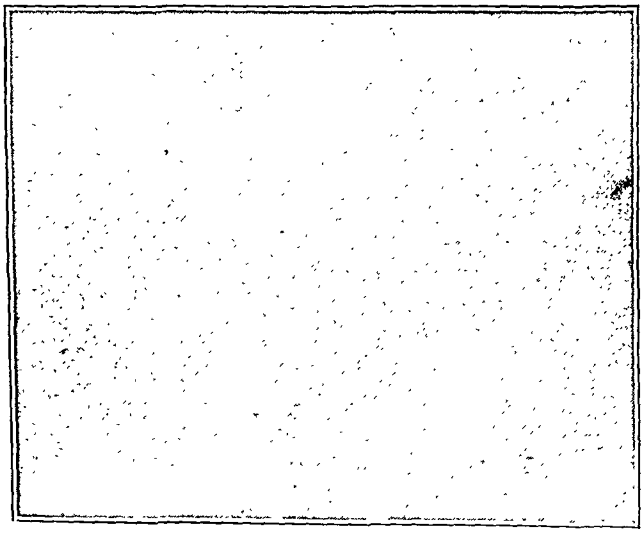

Fig. 4.—Sacralization of the fifth lumbar vertebra on the right side.

Very little can be done for such patients from a curative standpoint. They can, however, be relieved and markedly improved by some form of simple body brace and in the army most of them may be rendered suitable for domestic duty.

SACRO-ILIAC CONDITIONS

The question of sacro-iliac disease has been considered in the literature so fully that it hardly seems necessary to rehearse it again. Whether the sacrum slips forward, backward, upward or downward in the so-called dislocation, we will leave to the determination of those who are especially interested. There is not the slightest question that there is a pathologic condition of this joint and that the cases may be divided into infectious and mechanical groups. We have had two cases in which the infectious type seemed clearly established. One was an ordinary acute arthritis; the other was tuberculous in origin. Sacro-iliac dislocations or slips, as they are often termed, are relatively common. Soldiers with this affection give a history of recurrent attacks of pain in the back, coming on after lifting, usually while in a stooping posture. The pain is at first sharp and knifelike, but later develops into a dull ache. It is situated over the sacral region and localized on one side. It often radiates down the leg and in some cases is easily confused with the pain of sciatica or gluteal bursitis. Clinically these patients show spasm of the lumbar muscles and there is often a tilting of the pelvis toward the affected side. They complain of pain over the sacrum when bending forward and when the thigh is sharply flexed on the abdomen.

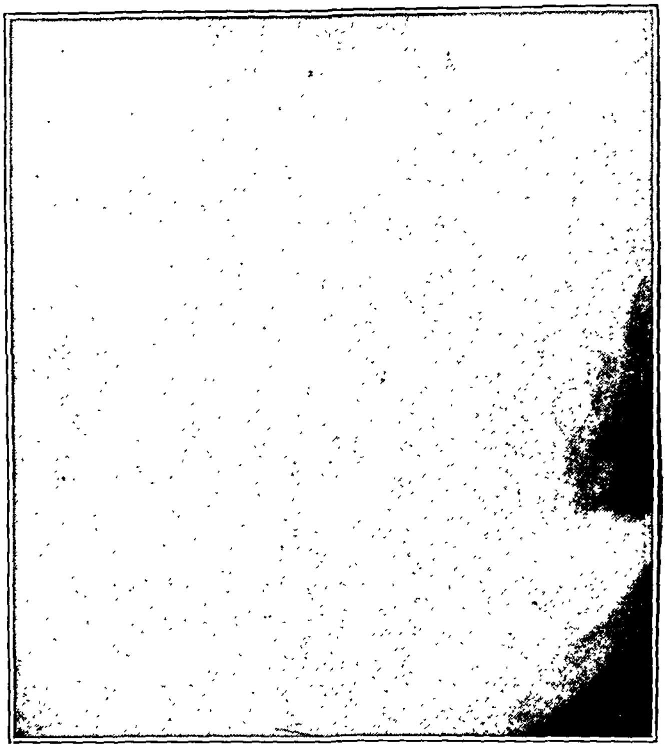

Fig. 5.—Lumbarization of the sacrum. A complete roentgenogram of the spine disclosed an extra lumbar vertebra with a congenitally deformed sacrum.

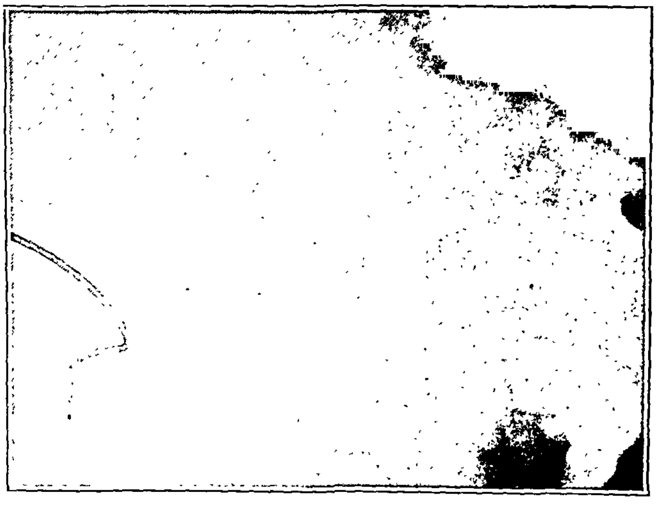

Fig. 6.—Destruction of the transverse process of the fourth lumbar vertebra due to tuberculosis—catheter in sinus tract.

Many of them complain of increased pain when asked to stand on the leg of the affected side alone. When in a sitting or reclining posture they favor that leg and use it as little as possible in rising. Heavy percussion over the lower spine and sacrum elicits pain over the affected area. Pain on compression of the pelvis has been very rare in our experience. There is often tenderness over the joint on rectal examination and one of the striking signs has been tenderness over the symphysis. It has been present in about 60 per cent. of the cases. This can be readily explained in view of the roentgen-ray findings. It has been definitely shown that the chief roentgenologic finding in this type of case is a misalignment of the symphysis due to the shifting of the pelvic bones as a result of the displacement in the sacro-iliac joint.

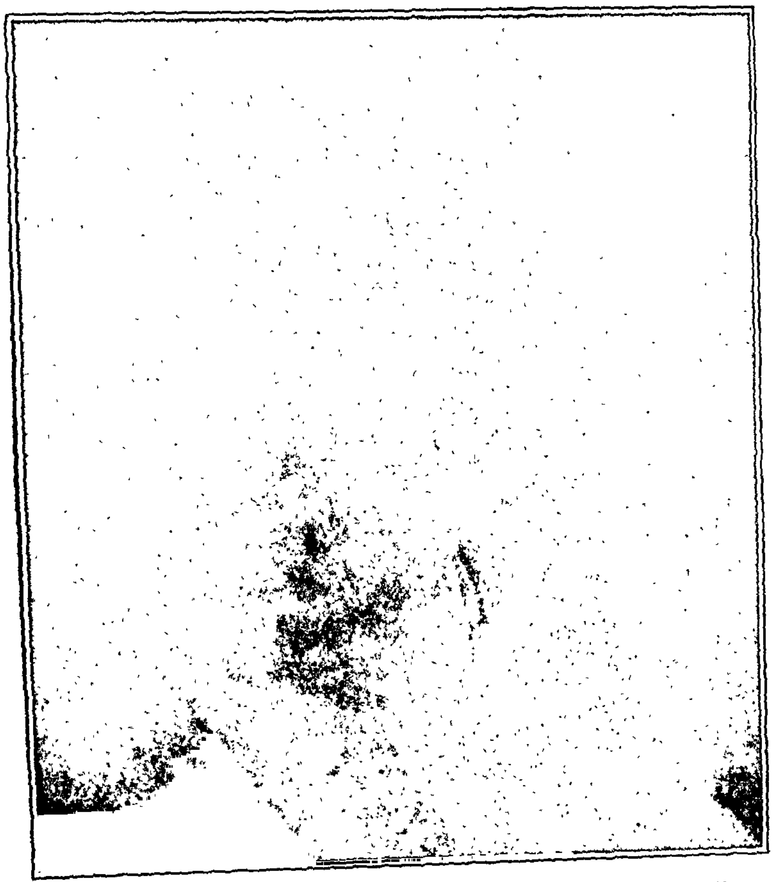

Fig. 7.—Old tuberculosis with destructive process of the bodies of the fourth and fifth lumbar vertebrae.

TYPE OF CASES ASSOCIATED WITH BACK PAIN IN ARMY GENERAL HOSPITAL NO. 1

	Number of Cases

Myositis (lumbar)	15
Congenital malformations	2
Curvatures (excluding above):	
Rickets	2
Postural curves	8
Total	139

The space between the pubic bones is wider than normal and their relative position is altered. The old method of looking directly at the joint and of observing the angle between the spinal column and the ilium we have found to be of no value. So reliable do we believe the altered relationship at the symphysis to be that every case in our series has been corroborated by the roentgen ray before being recorded as sacro-iliac disease.

TREATMENT OF SACRO-ILIAC DISEASE

With reference to treatment we have found it mainly palliative. In the beginning rest in bed with some kind of fixation, such as adhesive strapping, is indicated. We have tried all the manipulations described for reducing these displacements but have not met with success in a single instance. In the later stages baking and massage seem to be helpful. In strapping these patients we have found the following method to be the most serviceable. Two wide pieces of adhesive tape (4 inch) are overlapped as shown in Figure 1. These are reinforced by three throat sticks and a third piece of adhesive tape is placed over the sticks. The last piece is designed to support the throat sticks and also to prevent the adhesive tape from sticking to the pubic hairs. This part of the belt is now placed on the patient so that the middle throat stick is directly over the symphysis. The ends are then firmly fixed to the pelvic bones. Straps are now run across the back so as to overlap the ends of the original pieces. These straps are put on with a great deal of tension and are designed to give tight support. Adhesive strapping has been used early in all our cases; later sacro-iliac belts have been applied. The belt most in use here is one composed of brown canvas made very simply and held

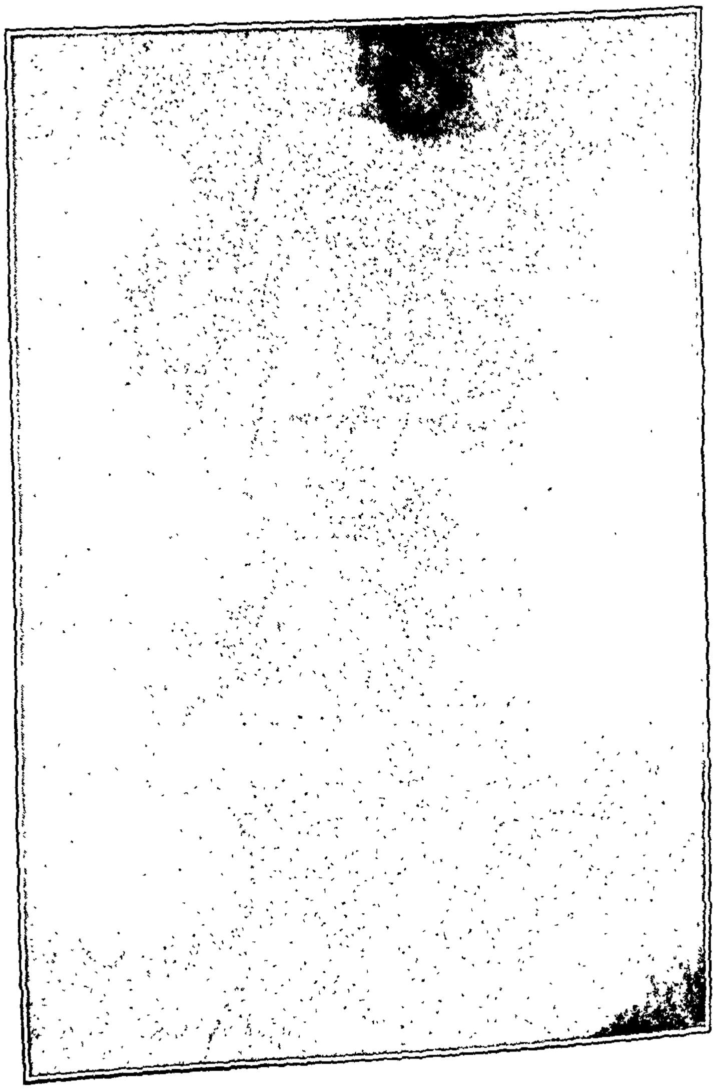

Fig. 8.—Spondylolisthesis.

in place by three buckles and two rubber perineal bands. As a class, patients with sacro-iliac trouble make poor soldiers. The recurrence of the disability is very common and makes their service uncertain. This is especially true if they are required to carry heavy packs or do much lifting. A few of our patients have been sent to domestic duty, and others have been given full duty in special branches of the service.

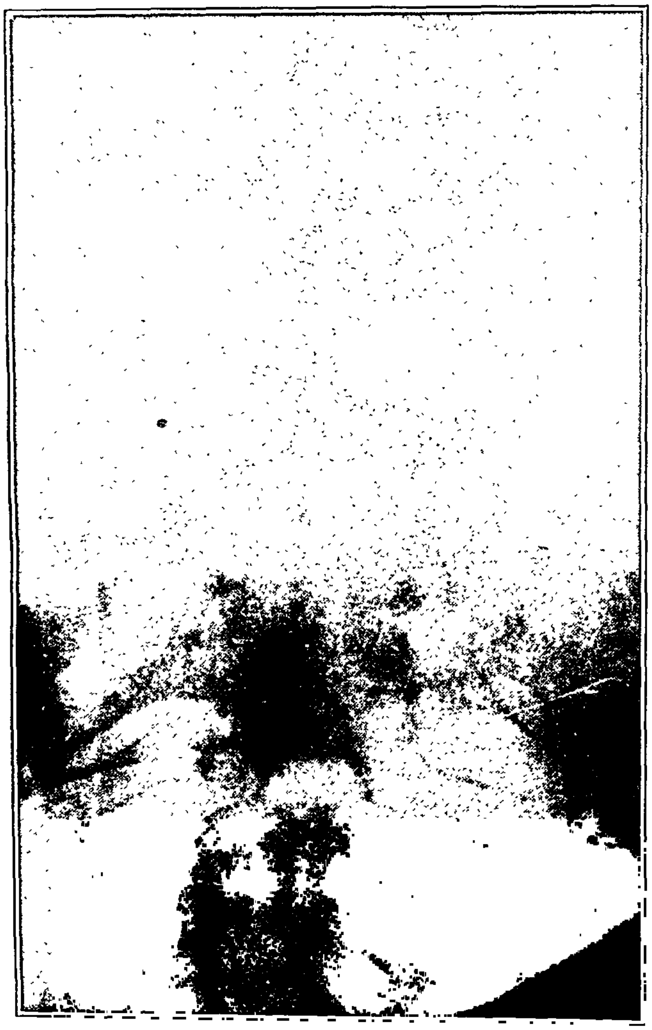

Fig. 9.—Hypertrophic arthritis with evidence of growth along the left lateral aspect of the fourth and fifth lumbar vertebrae associated with rotation.

SACRALIZATION OF FIFTH LUMBAR VERTEBRA

A condition closely associated with sacro-iliac dislocation is sacralization of the fifth lumbar vertebra. In these cases the roentgen ray shows an abnormally large transverse process which is irregular in shape and often impinges on the sacrum or ilium. The symptoms and signs are identical with those of sacro-iliac dislocations and it is that alone that makes the differential diagnosis possible. In many cases the two conditions are associated. Several cases have been reported in which this condition was relieved by an operative procedure. The two cases in our series were discharged.

INFECTIOUS CONDITIONS

Infectious diseases of the spine and its coverings include a large variety of cases and account for many instances of pain in the back. Myositis which is commonly called lumbago, is so familiar that it needs no discussion or elaboration. In the cases of infectious diseases of the spine seen at this hospital there were two soldiers with hypertrophic inflammatory growths or exudates along the bodies of the vertebrae: one of these gave a history of recurrent attacks of rheumatism. In this case the chief symptoms were those of nerve root compression. Both men were discharged as unfit for military service.

Besides these types of infections we have had one gonorrheal spine with ankylosis in the lumbar region, also one typhoid spine with destruction of the intervertebral disks. The soldier in the latter case was given a supporting jacket with good results. Both men were made fit for limited service only.

Two cases of syphilis of the spine were also seen. These showed rather marked destruction of the vertebrae. Both these soldiers were discharged after being given intensive syphilitic treatment and fitted with appropriate braces.

Fig. 10.—Osteo-arthritis involving dorsal and cervical vertebrae.

Spondylitis deformans is also grouped as an infectious condition and is closely allied to osteo-arthritis, of which we have had two cases. Three cases of spondylitis deformans were seen in our series. One was straightened under moderate head and foot extension. This patient was later given a jacket and sent to domestic service. The other cases were so disabling as to justify discharge.

Tuberculosis has been fairly common among spinal diseases in the army. Many of these are old healed cases, but there have been a considerable number of acute ones. The treatment in the acute cases is such as is now virtually standardized and consists in hygiene, heliotherapy, fixation, etc. We have seen no case of Pott's disease suitable for the bone graft operation of Albee.

CONGENITAL MALFORMATIONS

Congenital malformations of the spine we have found to be rather rare. Two such cases seen here are worth mentioning. One proved to be due to an extra pair of ribs which had their origin from the first lumbar vertebra and occurred in a patient who complained of pain directly over this area. Another was a case of lumbarization of the sacrum. This soldier had an extra lumbar vertebra and a small, malformed sacrum. His chief complaint was pain over the sacral region, which was readily accounted for by the roentgen ray findings.

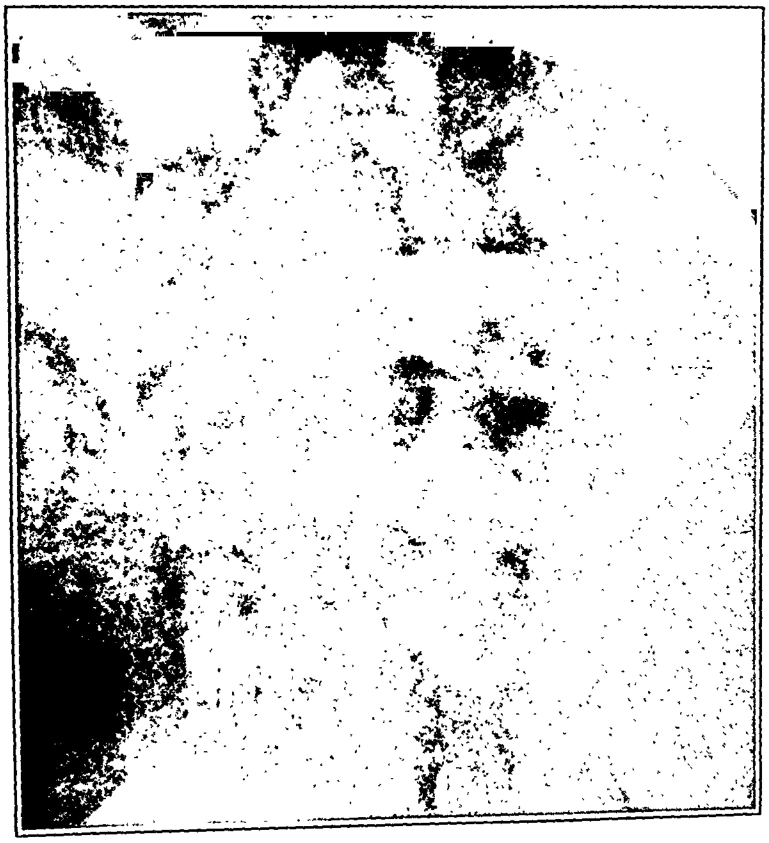

Fig. 11.—Hypertrophic arthritis with evidence of growth along the right lateral aspect of the fourth and fifth lumbar vertebrae and a shifting of the fourth lumbar vertebra to the left.

SPINAL CURVATURES

All varieties of spinal curvatures have been seen. Those which were functional were readily improved by remedial work combined in a few cases with a light support. The effect of remedial exercise was espe-cially gratifying in the cases of empyema associated with postoperative curvature, early sustained breathing combined with spinal calisthenics proving especially beneficial. The structural curves were found most frequently in cases of old tuberculosis. Two cases which were rachitic in origin were in the group of spinal curvatures. In the entire group of patients seen only one case of suspected tumor occurred. This at first was considered to be sarcoma but later was proved tuberculous.

In summing up the cases of back pain we wish to tabulate the actual grouping of 139 cases studied in the orthopedic division of the department of surgery at this hospital during the last six months. We believe the classification will represent the ordinary type of cases associated with back pain, as seen in army general hospitals.

In studying these cases we have been impressed by the infrequency of malingerers and by the comparatively small number of cases in which some pathologic condition of the spine or its coverings could not be actually demonstrated. We desire to emphasize the thoroughness with which cases of back pain should be studied, and to call attention to the necessity of group cooperation in order to arrive at proper conclusions. In this hospital the so-called orthopedic work is so intimately a part of the general surgical service that it has been possible to study and manage this field of our work with mutual interest and benefit to all concerned.

In presenting the roentgenograms we are particularly indebted to Major L. G. Cole and Capt. H. B. Podlasky for their enthusiastic cooperation and valuable aid in enabling us to arrive at certain definite conclusions. Roentgenologic interpretation alone was in many cases responsible for diagnoses that would otherwise have remained undetermined.

STUDIES IN INFLUENZA AND PNEUMONIA

II. THE EXPERIMENTAL PRODUCTION OF SYMPTOMS AND LESIONS SIMULATING THOSE OF INFLUENZA WITH STREPTOCOCCI ISOLATED DURING THE PRESENT PANDEMIC *

E. C. ROSENOW, M.D.
ROCHESTER, MINN.

During a study made some years ago[1] on the influence of environment on the pneumococcus-streptococcus group of micro-organisms, I noted marked changes in morphology, growth characteristics, infecting powers and immunologic reactions. Many of these changes appeared to be true mutations. Observations I have made since then, particularly during this epidemic, corroborate those findings and suggest the possibility that the present pandemic may be the result of infection by mutation forms of this group of micro-organisms. In studying the infecting power and other properties of streptococci when they are first isolated from tissues and foci of infection in various diseases including poliomyelitis, certain strains of streptococci which produce green discoloration on blood agar and which have peculiar infecting powers, specific immunologic properties and etiologic relationship have been found. In view of these facts, which are regarded as fundamental, it was thought possible that the peculiar clinical and pathologic picture of influenza, its accompanying pneumonia, and other lesions might be due to bacteria having peculiar infecting powers and other specific properties. The presence of a pandemic strain among the varieties of pneumococci and streptococci isolated by many observers was considered possible.

[1] Rosenow, E. C.: Transmutations Within the Streptococcus-Pneumococcus Group, J. Infect. Dis. 4: 1-32, 1914.

The somewhat peculiar green-producing streptococcus, described in a previous paper,[2] has now been isolated quite constantly from a large series of cases of influenza. In making cultures from the blood, from the lung exudate, and from peribronchial lymph glands in patients who died from acute pulmonary edema and pneumonia, we were struck by the fact that the former was often sterile or contained few colonies and that the number of bacteria, particularly green-producing streptococci, were few in number in the latter as compared, for example, with that found in lobar pnuemonia. Following intraperitoneal injections in guinea-pigs of the sputum and cultures, invasion by this organism was found in most instances, but, as in persons with influenza, the number of organisms in the blood was strikingly small and far less than that found in animals dead from intraperitoneal injections of type pneumococci. A special mechanism for the cause of death was thus indicated. In the animals it was found that the organism, when injected intraperitoneally or intravenously, tended to localize in the lung and to produce hemorrhages and bronchopneumonia, associated with a varying degree of emphysema (Fig. 1). This was not noted in animals dead from intraperitoneal injections of type pneumococci. The average volume of the lungs, the total displacement of water of guinea-pigs weighing about 350 gm., was found to be as follows: normal guinea-pigs killed with chloroform, 5.2 c.c.; guinea-pigs dead of intraperitoneal injections of type pneumococci, 6.7 c.c.; and guinea-pigs dead from intraperitoneal injection of sputum and green-producing streptococci from influenza, 12 c.c. Since localization tended to be in the lung it was thought that direct application of the organism to the respiratory tract might afford better opportunity to study the peculiar infecting power of the bacteria found during this pandemic.

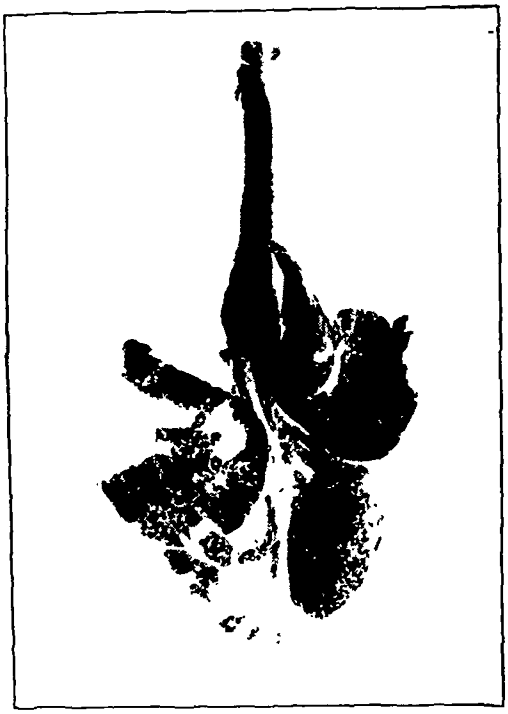

Fig. 1.—Lung of guinea-pig 761, injected intraperitoneally, showing hemorrhage, bronchopneumonia and emphysema. Total volume 12 c.c.

A simple method for intrabronchial injections of guinea-pigs was devised similar to that used in dogs by Lamar and Meltzer and in rabbits by Winternitz and Hirschfelder. Discarded ureteral catheters cut at an angle of 45 degrees with the margins rounded are used to make the injections. The guinea-pig is wrapped in a towel, the head held in place by the handles of an inverted artery forceps., The mouth is held open by spring wire retractors and the tongue is depressed by a suitable small instrument. Under a strong reflected light, properly shaded, the catheter is inserted into the larynx with a quick stroke before the contraction of the muscles of the epiglottis can divert the tube into the esophagus. The animal's sharp, quick cough and total inability to use its voice, and the sensation of the catheter's passing the tracheal rings, indicate that it has entered the trachea. The injections, varying from 0.1 c.c. to 2 c.c. in amount, are made slowly through the catheter with a syringe and needle.

By this method numerous experiments have been done with various strains of bacteria, including pneumococci, green-producing streptococci, hemolytic streptococci, staphylococci and influenza bacilli from persons with influenza as well as those from normal persons and other sources. The details of these experiments are reserved for subsequent reports; the purpose of this paper is to record a brief summary of the principal results obtained with strains of the green-producing streptococci and pneumococci belonging to Group IV from cases of influenza. By intrabronchial injection of these organisms a picture simulating influenza and pneumonia has been produced. Numerous animals have succumbed to acute pulmonary edema, to bronchopneumonia, to pneumonia involving whole lobes, and to acute hemorrhagic exudation in the pleura and peri-

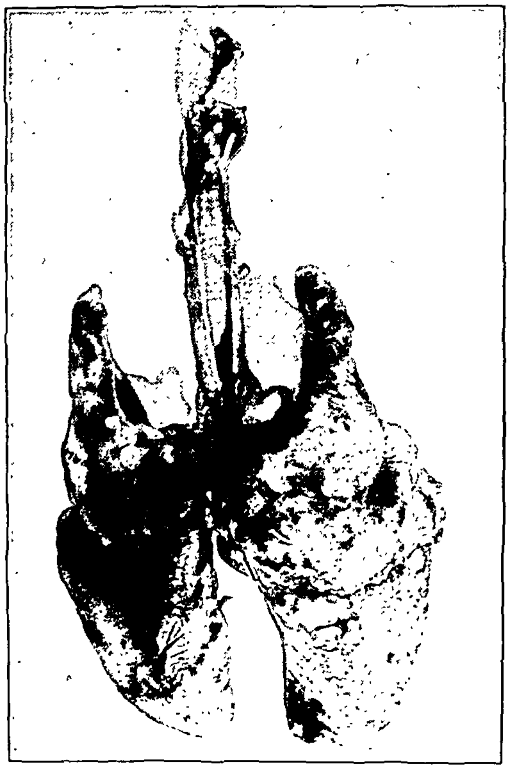

Fig. 2.—Lung of guinea-pig 851, injected intratracheally, showing coalescing bronchopneumonia of enlarged right lower lobe. Total volume 18 c.c.

[2] Rosenow, E. C.: Prophylactic Inoculation Against Respiratory Infection During the Present Pandemic of Influenza, Preliminary Report, J. A. M. A. 72: 31, 1919.

cardium together with marked or slight lung involvement.

The lungs of these animals, as in persons with influenza, were often voluminous. Many showed acute symptoms resembling anaphylactic shock and typical bronchial spasm a few minutes after intratracheal injection. The type of respiration in the animals that lived twenty-four hours or longer was often very different from that in the animals having respiratory embarrassment from extensive consolidation of the lung following injection of pneumococci from lobar pneumonia, or of mass cultures from throats of normal persons. In the former, the chest was often in almost complete expansion, the animals were irritable and restless, expiration was prolonged and difficult, and breathing was accomplished chiefly with the diaphragm. Injections of epinephrin and atropin in large doses often relieved the respiratory embarrassment. In the latter group of animals the respiration was normal in character, excursions of the chest were free and easy, and the animals were quiet, but the rate was often much increased, depending on the amount of consolidation. Injections of epinephrin and atropin were without effect. The lungs in the first group were often extremely emphysematous and contained much hemorrhagic edematous fluid (Fig. 2). The massive bronchopneumonia was the rule in the animals that died late (Fig. 3). The rupture of alveoli, manifested as subpleural blebs, has been noted in animals showing extreme emphysema and hemorrhage. In a number, air was found in the mediastinal tissues, and several showed subcutaneous emphysema about the thorax. Sections of the lungs showed extremely narrow lumens of bronchi often filled with exudate. The mucous membrane appeared in great folds and the cartilages in the wall of the larger bronchi were often distorted as a result of the extreme spasm of the bronchial muscles (Fig. 4). The marked constriction of bronchi must have occurred before death and was not due to the fixation in 10 per cent. formaldehyd solution, since the total volume of lungs after fixation in formaldehyd solution (Kaiserling's solution) was found to be only about one-sixth less than that of the fresh lung. This picture is identical to that of the anaphylactic lung obtained by the usual methods, except that marked edema and hemorrhage occurred in the mucous membrane of the trachea and bronchi and in the interstitial tissue and the alveoli. The lungs of animals injected with type pneumococci, or with mass cultures from influenza and from normal persons, were not much larger than normal. The mucous membrane of the trachea and bronchi appeared normal. There was little hemorrhagic edema, but a variable amount of consolidation occurred, usually of the lobar type. The bronchi were not constricted and the dilatation of alveoli was absent. In addition to the picture in the lung, many of the animals aborted and many showed localization in the uterus. The picture of influenza was simulated in still other ways. There was delayed coagulation of the blood obtained from the heart and lung exudate in the animals, as in persons dead from influenza. Leukopenia usually occurred following injection of the strains. Leukocyte counts were made in 195 animals, following injections of numerous strains and their filtrates. Eighty-eight of these showed marked leukopenia, forty-one moderate leukopenia, thirty no change, thirty marked increase, and thirteen slight increase in leukocytes. The strains from patients showing marked leukopenia produced, usually, leukopenia in animals, while those from patients with leukocytosis usually produced leukocytosis in animals. Many animals (Table 1) showed leukopenia for a day or two; they appeared sick or prostrated; and, as recovery ensued, the leukocyte count increased. A persistent leukopenia was the rule in the animals that died.

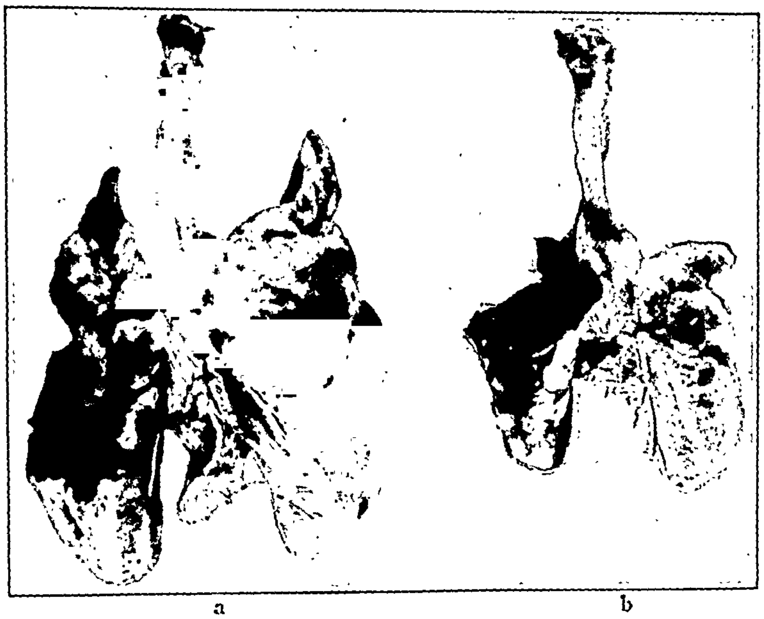

Fig. 3.—*a*, lung of guinea-pig 968, injected intratracheally, showing marked hemorrhagic edema and emphysema. Total volume, 22 c.c. b, lung of guinea-pig of same weight dead from spontaneous pneumonia. Total volume 6.5 c.c.

In Table 1 are given the leukocyte counts in a series of animals following the injection of a number of strains, together with controls injected with type pneumococci. All but one of nine animals injected with Strain 2800 showed a marked or moderate leukopenia, while one showed slight leukocytosis. This difference in the behavior of an occasional animal was noted with other strains. The results as shown in Table 1 represent in a general way those obtained throughout these experiments. In some instances the cultures and their filtrates became so toxic that very small doses sufficed to cause hemorrhagic edematous frothy fluid to exude from the nose and mouth before death, and marked emphysema and hemorrhagic edema of the lung were

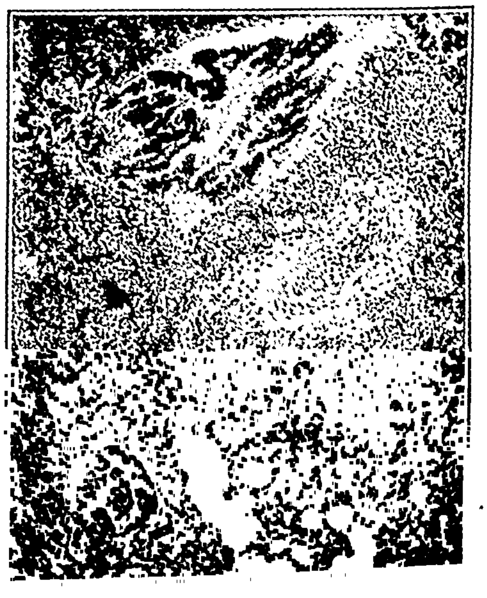

Fig. 4.—Section of lung shown in Figure 3 *a*, showing marked dilatation of alveoli, extreme contraction of bronchi, interstitial and alveolar hemorrhage, and infiltration. Hematoxylin and eosin. × 70.

found after death. One filtrate was so toxic that the instillation of 0.3 c.c. into the nostrils of a guinea-pig caused death in forty minutes from hemorrhagic edema and emphysema of the lung.

The freshly isolated strains from influenza and its accompanying lesions have been found to produce relatively large amounts of "anaphylatoxin" both in vitro and in vivo. The idea that the "virulence" of these bacteria may depend in part on their ability to produce "anaphylatoxin" is in accord with my[3] previous findings that virulent pneumococci and their filtrates produce a larger amount of this toxic substance than avirulent pneumococci. The picture in animals is clearly that of an anaphylactic intoxication, and suggests that the symptoms and lesions in man as recorded by numerous observers may likewise be due to this cause in which sensitization of the host to the bacterial proteins may or may not play a part. Findings as follows indicate this mechanism: (1) the delay in the coagulation time of the blood, leukopenia and cyanosis; (2) the marked tendency to develop acute pulmonary edema with a distended lung and relatively immobile expanded chest, and extreme respiratory effort; (3) the voluminous lung as found at necropsy; (4) the occurrence of the rupture of alveoli and consequent subcutaneous emphysema (bronchial spasm); (5) the frequency of abortion (contraction of unstriped muscle) and other uterine disturbances.

* The figure to the right and above the figures indicating the strain designates the animal passage; the one following the period, the subculture.

From this study it is clear that among the green-producing streptococci isolated by many observers in influenza and the accompanying pneumonia, a strain or strains occur which possess marked and peculiar virulence. By intratracheal injection of these strains the picture of influenza has been closely simulated.

PROTOCOLS ILLUSTRATIVE OF SOME OF THE RESULTS OBTAINED

Protocol 1.—Guinea-pig 761, weighing 350 gm., was injected intraperitoneally, Nov. 26, 1918, with 3 c.c. of the dextrose-brain-broth culture from a single colony of the green-producing streptococcus isolated on blood agar plates from the sputum of a typical case (Strain 2611) of influenza. November 27 the animal appeared quite well; November 28 it appeared sick, respirations had increased. November 29 it was found dead. Serofibrinous peritonitis and moderate emphysema of the lungs, a total volume of the lungs of 12 c.c., localized hemorrhagic edema and bronchopneumonia of the right apical, cardiac and diaphragmatic lobes were found. The lung was edematous on the cut surface, and the edematous areas were surrounded by marked emphysema (Fig. 1). The pleura was normal. November 30, blood agar cultures of the blood revealed a moderate number of green-producing streptococci and a few staphylococci; those of the lungs showed a large number of green-producing streptococci and a few staphylococci, while blood agar cultures of the peritoneal exudate revealed countless numbers of green-producing streptococci and many staphylococci.

Protocol 2.—Guinea-pig 851, weighing 500 gm., was injected intratracheally, Dec. 28, 1918, with 0.5 c.c. of the dextrose-brain-broth culture of a green-producing streptococcus from the sputum of a case of typical influenza (Strain 2749) after one animal passage. Jan. 3, 1919, the animal died. Marked cloudy swelling of the myocardium, distention of the right ventricle, hemorrhages in the adventitia of the pulmonary artery, voluminous lungs weighing 20 gm., with a total volume of 18 c.c., and marked hyperemia of the mucous membrane of the trachea and bronchi were found. The right diaphragmatic lobe was almost completely consolidated. The consolidattion was clearly lobular in character, but numerous similar areas were completely coalesced. The left pleura was normal and the right was covered with a thick layer of adherent fibrin, particularly opposite the gray areas of consolidation (Fig. 2). There were no areas of softening; but a number of circumscribed areas of hemorrhage and edema in the emphysematous lobes were noted. Jan. 4, 1919, blood agar plate cultures of the blood showed a few colonies of the green-producing streptococcus; the pleural exudate, the pneumonic lung, the kidneys, and the mucous membrane of the nose showed countless numbers, while the edema fluid from the circumscribed areas in the emphysematous lung and the adrenals showed a few.

Protocol 3.—Guinea-pig 968, weighing 380 gm., was injected intratracheally Jan. 14, 1919, at 3:30 p. m., with 2 c.c. of the dextrose broth culture of the hemorrhagic vaginal discharge from a fatal case (Strain 2800) of influenza. Blood agar plates of the culture injected showed countless numbers of green-producing streptococci and a moderate number of colon bacilli. At 7:30 p. m., the respiration was difficult and greatly increased. The animal was restless and irritable and coughed at intervals. At 7:40 p. m., the condition was worse; respirations were extremely rapid and labored, and a bloody fluid was noted about the nostrils. At 7:42 p. m., the animal had a violent attack of bronchial spasm, in which it threw itself about in the effort to breathe. It bled profusely from the nose and mouth, and died three minutes later. The lungs were heavy and enormously distended; their total volume was 22 c.c. (Fig. 3 *a*). Numerous large and small hemorrhages were found throughout all the lobes. The alveoli, in places, appeared at the rupturing point. There was a small amount of bloody fluid in the pleural cavities. A large amount of bloody frothy fluid escaped from the larynx, and the nostrils were filled with similar material. The cut surface of the lung was extremely moist, dark red, and a large amount of hemorrhagic frothy fluid escaped. There were two small hemorrhagic fetal masses, one in the vagina and the other at the bifurcation of the uterus. The uterine horns were hyperemic. The placental mass surrounding the fetuses was hemorrhagic. A number of small hemorrhages were found in the mucous membrane surrounding the point of placental attachment. The amniotic fluid was clear and smears showed no bacteria.

[3] Rosenow, E. C.: On the Toxicity of Broth, of Pneumococcus Broth Culture Filtrates, and on the Nature of the Proteolytic Enzyme Obtainable from Pneumococci, J. Infect. Dis. **11**: 286-292, 1912.

January 16, the blood and mucus from both horns of the uterus were sterile. The lungs and kidneys showed a large number of green-producing streptococci and colon bacilli; the pleura showed colon bacilli, and the adrenal, spleen and liver showed a few colonies of colon bacilli.

Sections of the lungs showed a striking picture of marked contraction of the bronchi, extreme dilatation of the smaller vessels, interstitial hemorrhage and cellular infiltration alternated with areas showing marked dilatation of alveoli. The dilated alveoli were often distended with edema fluid, blood corpuscles and leukocytes, or they were empty (Fig. 4). In the denser areas of hemorrhage and infiltration, the outline of the walls of the alveoli were wholly lost from edema and infiltration of interstitial tissue. The denser areas of infiltration were situated around the bronchi. A large number of gram-staining diplococci and a few bacilli were found in the infiltrated areas, both within the alveoli and the interstitial tissues.[4]

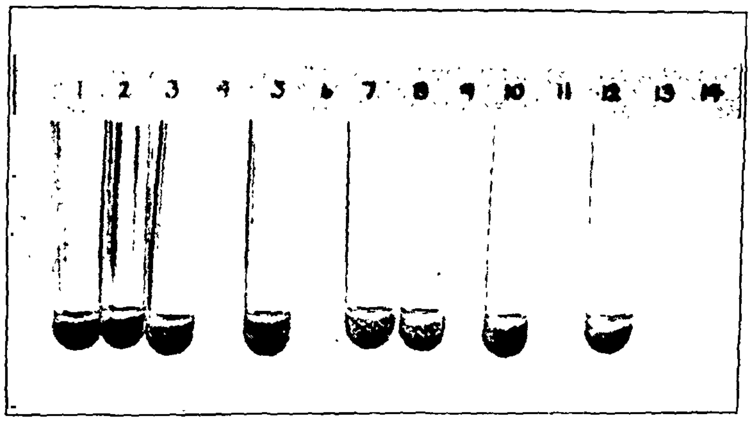

Fig. 5.—Photograph of experiment showing specific agglutination of streptococcus (Strain 3276) from influenza. Dilutions of serums 1-20. Tubes 1, 2, and 3 contain pneumococcus Types I, II and III serums; Tube 5 contains hemolytic streptococcus serum, Horse 9; Tubes 7 and 8 contain the monovalent serum following the injection of one strain of green-producing streptococcus from influenza, the former from a bleeding made March 3, the latter from a bleeding made May 4. Note the greater agglutination in the latter serum, Tube 8; Tube 10 contains normal horse serum; Tube 12, salt solution.

III. THE OCCURRENCE OF A PANDEMIC STRAIN OF STREPTOCOCCUS DURING THE PANDEMIC OF INFLUENZA *

The uniformity of symptoms in typical influenza suggests that the cause is a single bacterium having pandemic characteristics. The uniformity of the isolation of the somewhat peculiar green-producing streptococcus, previously described,[5] early in influenza and in the accompanying pneumonia, and the regularity of the invasion by this organism following the injection in guinea-pigs and mice, indicated early in the work that a pandemic strain might be found among this group of streptococci. The experiments following intratracheal injection, in which the picture of this disease is closely simulated, further indicate this possibility, and immunologic experiments were therefore instituted. I wish briefly to record here the main results obtained.

The serum of convalescent patients has been found to agglutinate specifically some of the more sensitive strains. The increase in agglutinins has been noted as early as the third day of typical influenzal attacks. The serum of cases that occurred early in the epidemic is found to agglutinate strains isolated then and kept in 50 per cent. glycerol as well as those isolated now, and vice versa. The results given in Table 2 suffice to illustrate those obtained in a large series of cases. The amount of agglutination with the different strains varies greatly and some strains are not agglutinated at all.

A monovalent immune serum has been prepared in a horse with one of these strains isolated from the blood in a typical fatal case. The horse has been injected with increasing amounts, first with the dead bacteria and later with the living. The serum has developed marked agglutinating power (Fig. 5) over these strains, agglutination occurring in dilutions up to 1:1,000 and 1:10,000.

The agglutinating power of various immune horse serums, as indicated in the tables, has been tested against numerous strains isolated from the sputum, throat, blood, and lung exudate. The well known methods for determining types of pneumococci, with minor modifications, were used. These included the animal inoculation method as worked out by Cole and the dextrose-blood-broth method as worked out by Avery. The various serums indicated in Table 3, were diluted 1:10 and equal amounts of this and the broth culture or suspension (0.2 c.c.) were placed in each tube and mixed, incubated one hour, placed in the ice chest over night, and then readings were taken. This dilution was found, after a series of titrations, to be best suited for routine purposes. Specific agglutinations with the monovalent serum as indicated in Table 3 have thus far been obtained in sixty-five of a total of ninety-eight cases studied. Some of these strains, just as has been found to be the case with the streptococcus from poliomyelitis, lose their specific character promptly on cultivation, while others remain susceptible to specific agglutination months after isolation. This was anticipated in the beginning of the work, and dense suspensions of the freshly isolated strains were placed in 50 per cent. glycerol. This method was proved efficacious in studying the specific properties of the poliomyelitis strains, and has been found equally useful in this study. Many strains isolated in the beginning of the epidemic are agglutinated specifically by this serum prepared with a single strain isolated early this year (January, 1919), just as are the strains from typical influenza isolated since then. The cases studied came from widely separated communities. Most of the negative agglutinations occurred when the cultures were made during convalescence. The results in some typical cases, however, suggest the possibility of subgroups. The specific strain, according to this test, has been isolated from the sputum as early as the first day of influenza, from the sputum in the accompanying pneumonia, and from the blood and lung exudate after death. It tends to disappear promptly during convalescence and is rarely found in normal throats. Strains of green-producing streptococci from a wide range of sources are rarely agglutinated by this serum. In studying the agglutinating power of various immune serums over strains from the sputum daily or on alternate days throughout the disease, it has been found that the strains are agglutinated specifically by this serum throughout the course in typical cases in which the patients recover without developing pneumonia or in which the pneumonia is of short duration. This is not usually true, however, of patients with protracted or recurring pneumonia, especially those who die (Strain 3276, Table 3). In these there may be a shifting of agglutination to pneumococcus serums, Types II or III, to hemolytic streptococcus serum, or, more often, they may not be agglutinated by any of the serums. Most of the specific strains, according to this test, do not ferment inulin and are not bile-soluble.

* The figures to the right and above the figures indicating the strain indicate the animal passage, those to the right of the period indicate the culture generation.

The results obtained in this series of experiments are illustrated, in the main, in Table 3. It will be noted that the primary cultures (Strains 3208, 3297, 3301, 3302, 3276) and the peritoneal washings from mice (Strains $3225,^2$ $3226,^2$ $3227,^2$ 3231^2) were agglutinated specifically by this serum (Horse 15) in every instance as were the cultures from single colonies after animal passage (Strains 3208^2.2, 3276^2.2). The result in the third column (Strain 3208.2) shows that it is not always possible to fish the specific strain when the sputum or other material is plated directly.

Many strains of the green-producing streptococcus from influenza have acquired hemolytic power in my hands and resemble closely the hemolytic streptococci isolated from some of the cases, especially after death. The close relationship of the green-producing strains to hemolytic streptococcus is indicated, moreover, by the fact that the hemolytic streptococcus serum commonly manifests decided agglutinating power over them (Table 3).

The agglutination experiments show that the green-producing strains of streptococci from influenza are immunologically identical or closely related. If this is true, single highly agglutinable strains should absorb the specific agglutinins from the serum for all the rest. This has been found to be the case in a large number of tests. Strains isolated in the beginning of the epidemic absorb the agglutinins so that a large number of strains isolated recently are no longer agglutinated. The results with a number of these strains are given in Table 4. It will be noted that while the specific strain absorbed the agglutinins, Type II pneumococci, which were not agglutinated, removed few or no antibodies.

The symptoms and lesions of influenza have been closely simulated in guinea-pigs by the intratracheal application of green-producing streptococci from influenza. The existence of a pandemic strain among the green-producing streptococci or diplostreptococci in influenza is shown by the immunologic studies summarized in this paper.

CANCER OF THE PROSTATE

A COMBINED SURGICAL AND RADIUM METHOD OF TREATMENT

ROBERT H. HERBST, M.D.
CHICAGO

In 1915 Barringer described a method of treating cancer of the prostate by introducing a single needle containing radium through the tissues of the perineum into the tumor mass. It is a modification of this principle which I wish to present in this report.

While many excellent results have been obtained with radium in the treatment of superficial cancers, the results in the deeper seated neoplasms have not been very encouraging, owing largely to the difficulty of bringing the radium directly into contact with the involved areas. It is my belief that this is accomplished in cancer of the prostate by exposing the tumor both above and below and by inserting multiple needles, containing radium, in different directions, thus bringing the radium into contact with the most remote parts of the growth.

Authorities differ as to the comparative frequency of carcinoma of the prostate, statistics varying from 15 to 40 per cent., although a majority believe that about one in five neoplasms of the prostate belong to the malignant class. It is interesting to note that while the earlier writers considered the condition as being infrequent, recent literature shows that such opinions have undergone a marked change. This can be well explained as being due to our broader knowledge of the condition, improved methods of diagnosis and a more thorough pathologic investigation of removed glands. We have all had the experience of removing a gland which we believe to be benign only to be informed by the pathologist that areas of malignancy had been found. Cancer of the prostate may develop as a new growth or as a malignant degeneration of a preexisting benign neoplasm, or it may appear coincidently with a simple hypertrophy. In order to define the type of tumor in which this method of needling the prostate is applicable, I will make the following classification:

1. The tumor may consist of a benign hypertrophy undergoing malignant degeneration or accompanied by beginning malignancy. These tumors are, as a rule, readily enucleated, and it is only on being examined microscopically that they are discovered to be malignant. This type is often benefited and sometimes cured by simple enucleation or by excision, as described by Young.

2. Another class of tumors begin as malignant growths in the lower periphery of the gland and gradually spread along the posterior part of the prostate to the seminal vesicles and ejaculatory ducts. These tumors are too far advanced for radical removal, but the symptoms can be greatly relieved, life prolonged, and the patient possibly cured by the judicious use of radium applied by means of needles, to be described in detail later.

3. In a third class of tumors the surrounding tissues have become involved, metastases have developed and there is a marked degree of anemia and cachexia. This type is beyond any form of treatment other than possibly drainage of the bladder to relieve retention.

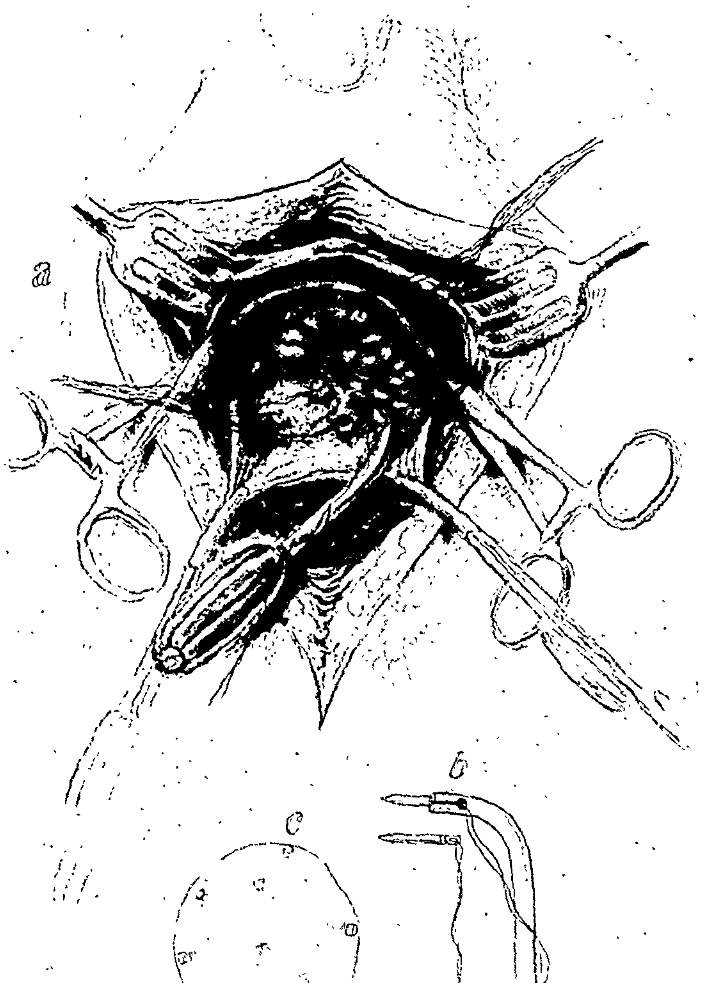

Fig. 1.—Operation for radium treatment of prostate cancer: *a*, suprapubic exposure of tumor, with the needles inserted in the tumor mass; *b*, needle carrier and needle; *c*, schematic view of position of needles after insertion.

SYMPTOMS

Unfortunately, the symptoms in cancer of the prostate are frequently not manifested until the condition is far advanced. This is particularly true of retention of the urine, which is a very early finding in benign hypertrophy. Irritability of the bladder may not develop until the disease has extended well up into the bladder neck. This is also true of hematuria. Although hematuria is a rather constant symptom, it is frequently of the terminal type. Pain at the end of urination is a common symptom. Pain accompanying the sexual act usually indicates the involvement of the lower end of the genital tract, the seminal vesicles and ejaculatory ducts. These patients sometimes complain of pain in the rectum radiating up the back, and down the thigh along the sciatic nerve. Residual urine is often a late manifestation.

Rectal examination usually reveals a stony hard, irregular, asymmetrical, nodular prostate. The rectal tissues are not movable on the tumor, and the tumor appears to be fixed. The term "frozen" has been used to describe this immobility. The prostate may not necessarily be greatly enlarged, but when one finds a hard, immovable prostate in a man of advanced years, one should be apprehensive of cancer. Loss of weight and strength and a marked secondary anemia are found as in other malignancies.

DIAGNOSIS

The diagnosis of cancer of the prostate is not necessarily difficult in an advanced case in which the patient complains of any or most of the foregoing symptoms, and on examination a hard, stony, immovable prostate is found. However, the patient to be most benefited is the one whose condition is discovered early, before many symptoms have developed, and in whose examination only a small, hard subcapsular nodule is found. In those cases in which there is a coincident carcinomatous development with a benign hypertrophy, the diagnosis of malignancy is frequently not made until the surgeon finds enucleation difficult or impossible. Whenever a prostate is enucleated with difficulty, one should be more than suspicious of malignancy. However, we must not lose sight of the fact that even easily enucleated glands on microscopic examination may show evidence of malignancy.

SELECTION OF CASES

Believing that radical excision of the malignant prostate cannot be carried out with any reasonable degree of safety and success except in the very early cases, we apply this method of radium needling to all advanced cases which do not show evidence of metastasis.

METHOD OF TREATMENT

A suprapubic cystotomy is made (usually under local anesthesia), with a liberal opening in the bladder wall so as to give easy access to the involved bladder neck, because in practically all these cases the tumor is fixed and cannot be pushed up into the bladder. A bimanual examination is then made to determine the limits of the tumor. By means of a needle carrier (Fig. 1 *b*), gold needles 1 inch in length, each containing 12 mg. of radium, are inserted into the tumor mass 1 cm. apart in different directions. The tumor is virtually converted into a pin cushion (Fig. 1 *a*). A silk guide, which is attached to each needle, is brought out of the suprapubic wound, and by means of it the needle is withdrawn. These needles are left in place for from twelve to fifteen hours, depending on how much of an exposure is desired. They are readily removed by traction on the silk guides. One such exposure will usually cause the removal of most of the upper part of the tumor, although this can be repeated after a few weeks if found necessary. As most of the tumors begin in the lower part of the gland, a second introduction of needles is made into this part of the tumor by making a dissection through the perineum and obtaining a complete exposure of the lower part of the prostatic mass (Fig. 2). It is well to allow from four to six weeks to elapse between the two steps of the operation. It may be readily seen that by this open method we are able to insert the unscreened radium directly into all parts of the tumor, and the action of the radium takes place in the center of the carcinomatous nodules. There is little reaction or pain following even long exposure. It is well to make the upper exposure first, because following the introduction of the radium a temporary swelling occurs, which is likely to cause complete retention, should the lower application be made first. I have not described this method of attacking the malignant prostate with the intention of reporting cures, because the number of cases treated has been too limited and the time since operation too short. However, some of the early results have been sufficiently encouraging to warrant reporting one of them, operation in which was performed ten months ago.

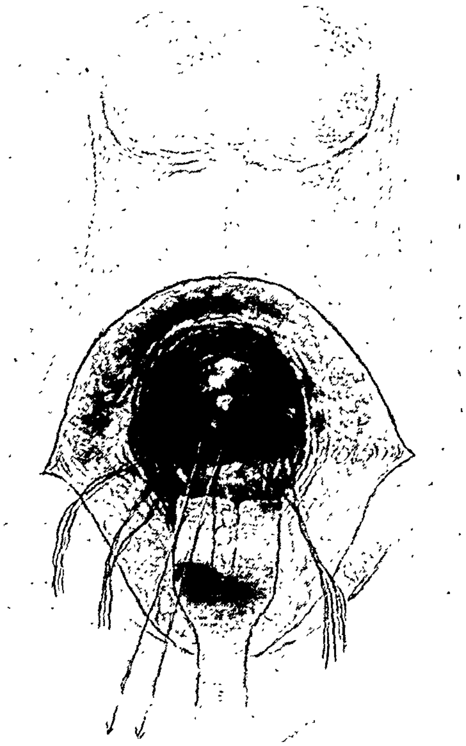

Fig. 2.—Perineal exposure of tumor with radium needles inserted.

REPORT OF CASE

A man, aged 66, was operated on about two years ago by an excellent surgeon for what was thought to be a benign hypertrophy of the prostate gland. On sectioning the removed tumor it was found to be malignant. The patient developed a prompt recurrence, and after a few months returned to the surgeon, who applied the radium to the tumor by introducing it into the rectum. Each one of these exposures, which were of short duration, with a moderate amount of radium, was followed by a severe reaction (radium, as a rule, is poorly tolerated in the rectum). After a number of these exposures the patient returned home in a greatly weakened condition, with little if any change in the size of the tumor. At this time he was referred to me. On examination I found a large, immovable, nodular mass occupying the site of the prostate gland. The patient was suffering from almost complete retention of urine, and catheterization was extremely difficult. He complained of severe pubic pain and great weakness. A suprapubic cystotomy was done and on inspecting the interior of the bladder, I found a large nodular mass projecting into the bladder in the region of the internal urethral orifice. By means of a needle carrier, eight needles, each containing 12 mg. of radium, were inserted into the tumor mass, about 1 cm. apart in different directions. These were allowed to remain twelve hours, and were easily removed by drawing on the silk guides attached to them. There was practically no reaction following this exposure. After six weeks the upper part of the mass had almost entirely disappeared. At this time a perineal section was made, thoroughly exposing the lower part of the tumor. A procedure similar to that described above was followed, and the needles were again allowed to remain in place for twelve hours. The wound was closed, sufficient space for the removal of the needles being allowed. Both suprapubic and perineal wounds healed in a few weeks. After a few months all that could be palpated was a moderate degree of infiltration along the urethra.

The patient returned recently for examination. Only a slight infiltration (probably fibrous tissue) could be palpated at the site of the tumor. He has regained all his lost weight, looks and feels well, has no residual urine, and his urinary function is good.

32 North State Street.

Responsibility.—City authorities are justly chanceable with the lives of all who die of preventable diseases within their jurisdiction, and they should be made responsible before the courts of justice.—Dr. Benjamin Rush.

Clinical Notes, Suggestions, and New Instruments

OSTEITIS FIBROSA

Joseph L. DeCourcy, M.D., Cincinnati
Surgeon, Seton Hospital; Assistant Attending Surgeon, Cincinnati General Hospital

REPORT OF CASE

F. L., a boy, aged 12, referred by Dr. Carroll DeCourcy, was admitted to the Seton Hospital, Jan. 13, 1918, with a fracture of the upper third of the left humerus, due to his having slipped on an icy pavement when coming home from school. Examination of the arm by palpation elicited an elongated, bony swelling in the upper third of the humerus, with point tenderness, crepitation and mobility at the corner of the swelling. The patient gave a history of having been vaccinated ten months previously, the reaction following the vaccination having been very severe. Whether the vaccination was a causative factor, is uncertain. For the last ten months the patient had continually complained of dull, rheumatic pains in the upper part of his arm, and was treated by medication and by external applications without relief.

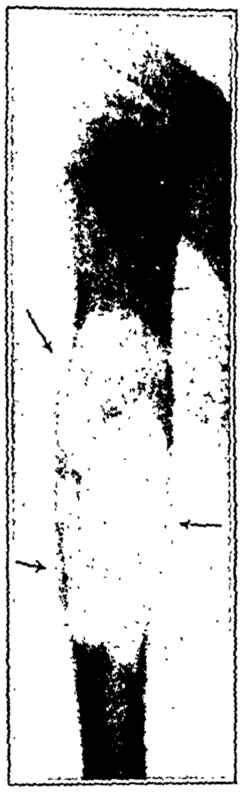

Fig. 1.—Arm of patient day following admission to hospital.

Fig. 2.—Arm of patient, one month after operation.

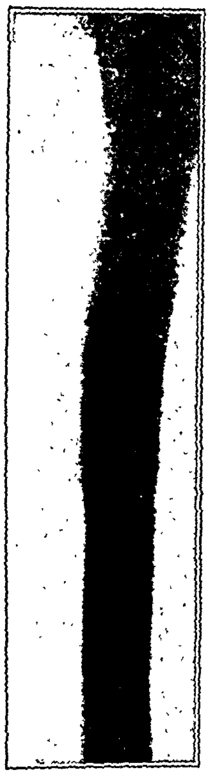

Fig. 3.—Arm of patient, ten months after operation; firm union between the two fragments.

The roentgenogram secured at the time of his admission to the hospital showed a rather marked absorption of bone in the upper part of the humerus, giving the impression of a cyst, and through this were shown fracture lines, considered to be pathologic features.

The operation, Jan. 18, 1919, revealed a cyst about 2½ inches in length, filled with bloody matter. The inside of the cyst wall was covered with what appeared to be granulation tissue. Because of the thinness of the cyst wall and the uncertainty of the diagnosis, the whole cyst, together with some healthy bone from each end, was resected, and a strip about 3 inches in length and one-fourth inch in thickness, of the boy's tibia, with periosteum, was transplanted into the medullary cavity of the upper and lower fragments. The periosteum was sutured over and the wound closed. The wound healed by first intention and the roentgenogram taken one month later showed the graft in position, with a large amount of callus covering it. Three months following the operation there is firm union between the two fragments.

On section, a few isolated giant cells were demonstrated. This, together with the gross appearance of the cyst, justifies us in making a diagnosis of osteitis fibrosa.

COMMENT

Eivind Platou,[1] in speaking of osteitis fibrosa, says that "trauma appears in many cases to be an etiological factor, although we are unable to explain how it can cause the disease or influence its genesis." In this case there was no history of trauma obtained, and if we can date the onset of the cyst from the vaccination, then it would seem that infection has played a part. It is possible that trauma so weakens the tissues that infection traveling in the blood stream can take hold.

It seems to be a matter of common agreement that the indicated treatment of these cases is curettage of the cyst cavity and then swabbing the cavity with some irritant for its stimulating effect. Bone grafting has been suggested in these cases a number of times, but does not seem to be in general use. It would seem that the uncertainty of the diagnosis of these cases from sarcoma, at the time of operation, would contraindicate curettage, for the same reason which contraindicates a removal of a section of a supposedly malignant tumor elsewhere. In other words, these bone tumors should be considered malignant until proved benign by microscopic study. And not alone for this reason, but because in the application of the bone graft we have a clean-cut piece of surgery which is uniformly successful in 100 per cent. of cases, if we can exclude infection, and its usage, in my opinion, should be encouraged in this type of case.

AN EXTRA TAG ON THE ABDOMINAL SPONGE*

J. C. Masson, M.D., Rochester, Minn.

The dramatic manner in which sponges are counted after each operation, in some hospitals, is evidence of the fact that "accidents still happen." It is quite probable that more medicolegal cases come to trial because something has been left in the operative field than because too much has been taken out of it.

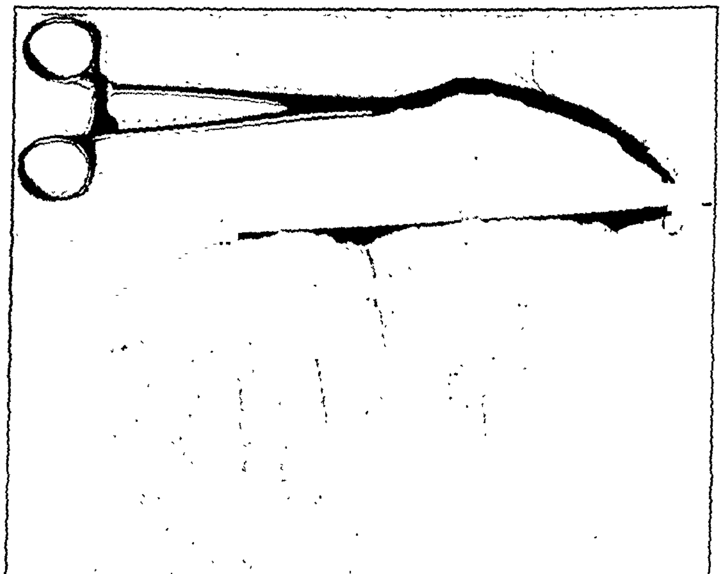

Fig. 1.—Abdominal sponge with ring attached.

Approximately 27,250 abdominal operations have been done at the Mayo Clinic within the last five years, and thirteen were for the removal of sponges. In most of these thirteen cases the patients came from rural districts, and had been operated on for acute conditions by general practitioners who probably had had very mediocre assistance and were further handicapped by the confusion attendant at such operations. The only wonder is that such accidents do not happen more often in this kind of surgery. After a more or less stormy convalescence, the patient recovers from the operation; but he is left with a persistent sinus, and while he has the original operator to thank for having saved his life, if he learns that a sponge has been left in the wound and is the cause of the sinus, he will seldom hesitate to enter action for unlimited damages.

* From the Mayo Clinic.

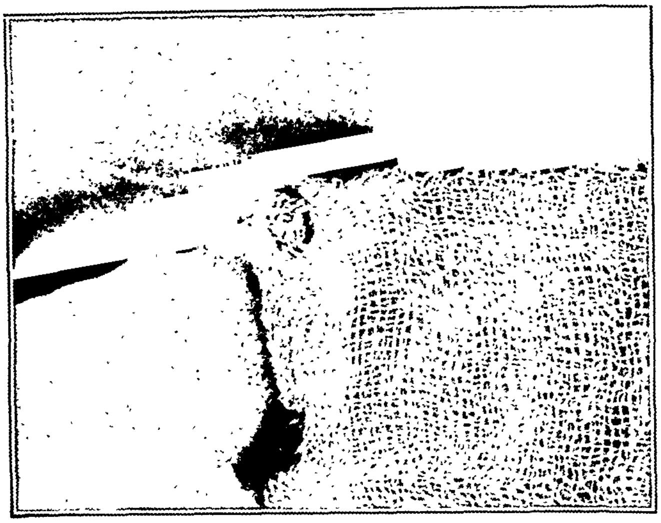

Fig. 2.—Abdominal sponge with ring attached.

With a view to the special marking of all abdominal sponges, I have them made with a metal ring placed around the base of the tape and firmly sewed to both sponge and tape with strong thread. If a sponge is reported missing, the abdomen may be rœntgenographed before it is reopened; the presence of the sponge will be revealed by the metal band. In hospital practice this procedure should be especially applicable, since if after a morning's work a sponge is reported missing and any one of two or three patients may be the unfortunate retainer, roentgenograms may be taken of all of them, and thus a difficult situation is cleared up with a minimum amount of trouble.

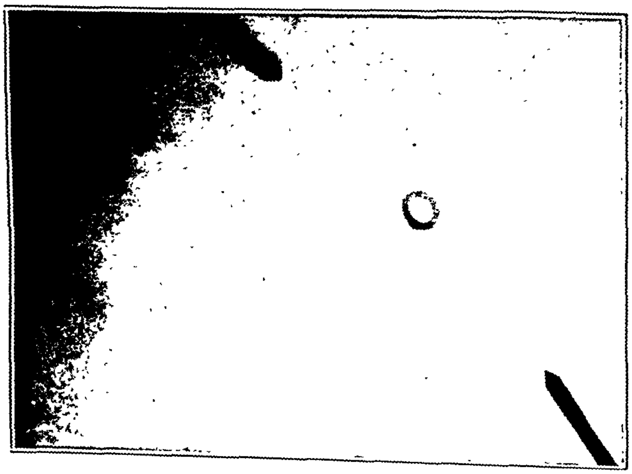

Fig. 3.—Roentgenogram showing sponge through a 200-pound patient.

The Sin of Ignorance.—Every mind was made for growth, for knowledge, and in its nature is sinned against, when it is doomed to ignorance.—Channing.

USE OF SUPERFICIAL JUGULAR VEINS OF NECK FOR INTRAVENOUS INJECTIONS

David J. Kaliski, M.D., New York

Not infrequently the practitioner is confronted with the difficult problem of finding superficial veins for the injection of arsphenamin or other arsenical preparations, saline solution or therapeutic serums, and for use in blood transfusion. To overcome this difficulty, I propose the more extended use of the external jugular veins.

In the majority of thin or muscular persons, especially men, the veins at the bend of the elbow in the cubital fossa are easily visible or palpable and should be chosen. Occasionally after numerous injections of arsphenamin these veins become occluded by thrombosis and are no longer available. In some cases these veins are mere threads and unsuitable for repeated injections. In obese persons, especially women, and occasionally in men and children with poorly developed veins, the operator is at a loss to find a suitable vessel into which to inject. Even the most skilful workers encounter these difficulties in hospital and private practice, and for this reason I have been prompted to describe my method of using the external jugular veins.

This method has been in use in selected cases in the wards of the Mount Sinai Hospital and in private practice, and hundreds of injections have been given without a bad result. The procedure is quite simple, presenting no greater difficulties than puncture of the veins of the arm, is not more painful, and is not attended with any greater danger to the patient. Indeed, up to the present time, I have not seen a single instance of thrombosis of the external jugular after injection of arsphenamin; and in a few instances the same vessel has been punctured repeatedly over a period of more than a year.

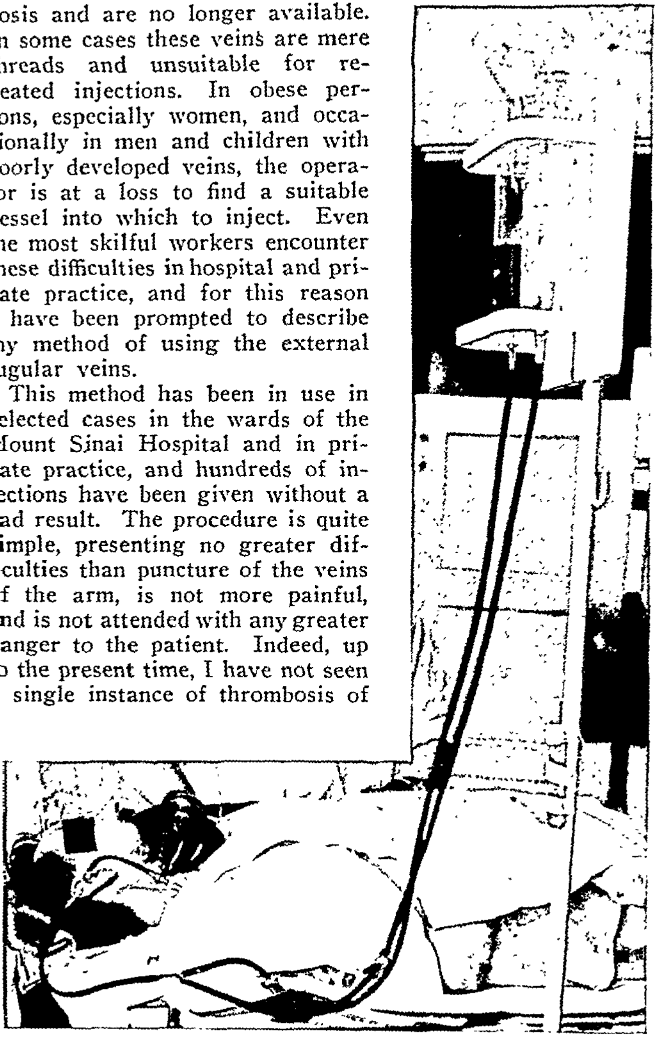

Fig. 1.—Method of making injection into external jugular vein (painted white), and apparatus used by the author.

The external jugular veins arise in the region of the parotid gland, on a level with the angle of the lower jaw, and runs down in the direction of the clavicle. They are not infrequently double, and even in children are good sized vessels. They cross the sternocleidomastoid muscle in its upper part, and run parallel to its posterior border; but there are frequent anomalies in size and position. The vessels terminate behind the clavicle in the subclavian veins. In most instances the vessels are superficial, being covered by the skin, superficial fascia and the thin platysma muscle, and stand out prominently especially on forced expiration or inspiration with compression above the clavicle, or on straining or crying. The anterior jugular veins are also occasionally quite large, especially at their lower part, where they approach and join the external jugulars. They are situated along the anterior border of the sternomastoid muscle.

TECHNIC

The patient reclines on a level table. No pillow is used, the head is turned slightly to one side. Compression may be made over the clavicle with the finger of the left hand in order to make the vein fill up and stand out more prominently while the right hand grasps the needle and pushes it through the skin and into the vein in a downward course in the direction of the vein axis. After practice in the method, almost any type needle may be used; but for greater ease of introduction, a needle with a shield like the writer's needle[1] is preferable. For arsphenamin and other therapeutic injections, a needle with a fairly sharp point, not too large bevel, and about 18 to 20 gage B. & S., about 1¼ to 1½ inches long, is most suitable.

In introducing the needle, the skin over the vein should be gently drawn upward toward the chin. This tends to fix the vein and to allow the needle to pierce the anterior wall of the vessel more easily. The skin of the neck is sometimes quite tough, and therefore the needle should not be too large or too blunt. As the needle enters the vein there is a perceptible "give" as the point enters the lumen. It should be advanced in the vein for about 1 cm. If the needle is properly in the lumen of the vessel, there is observed a slow dropping of blood from the needle, or a drop of blood comes into the hub of the needle (pressure above the clavicle having been removed) and is seen to advance and recede slightly on inspiratory efforts. It should be borne in mind that there is little bleeding from the jugulars compared with the amount of bleeding observed after puncture of a vein in the arm.

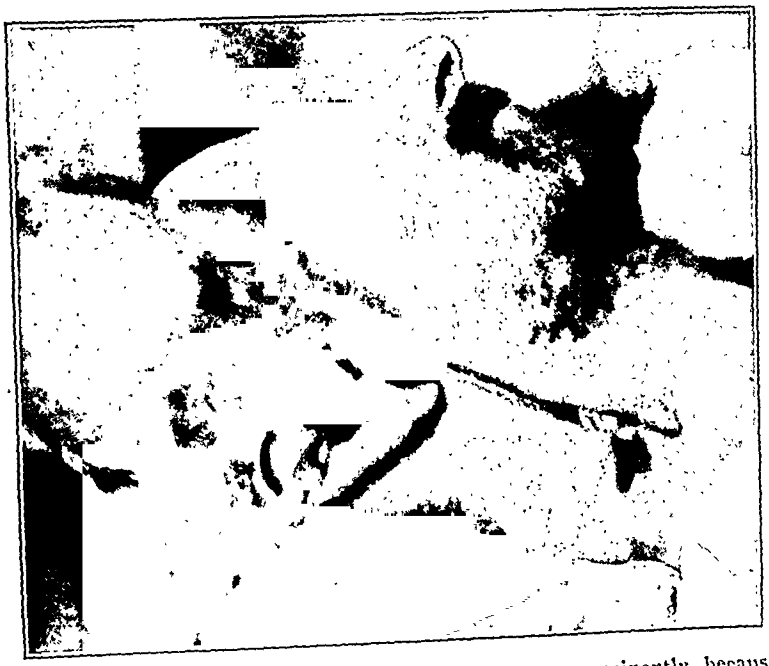

Fig. 2.—The external jugular vein stands out prominently because of fluid that is being injected.

The apparatus best suited for injection is the gravity apparatus, and care should be taken to free the tubing of all air bubbles before beginning the infusion. Saline or water should precede the medicament. If the needle is in the vein properly, the injection will proceed without any pain or infiltration at the site of the puncture. Care should be taken after the fluid has been introduced to remove the needle before the tubing is entirely empty to prevent the entrance of air bubbles. A small glass window made by the insertion of an inch of glass tubing in the rubber tubing near the coupler at the hub of the needle renders this impossible.

The most convenient site for introduction of the needle is in the lower third of the neck, but occasionally the vein is more prominent in the middle third, and the puncture should then be done there.

1070 Madison Avenue.

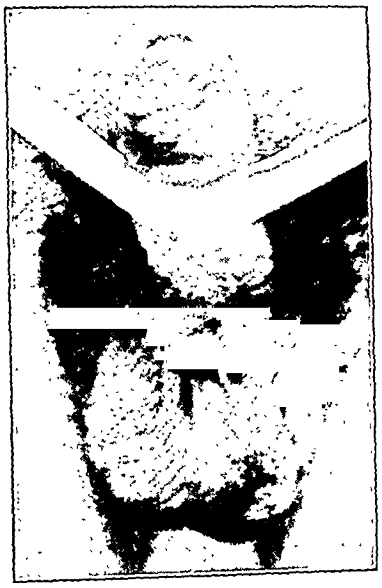
CROSS-RACIAL TRANSPLANTATION OF TESTES

FURTHER REPORT OF CASE

G. Frank Lydston, M.D., Chicago

Through the courtesy of Dr. L. L. Stanley, surgeon to the state penitentiary at San Quentin, Calif., I am privileged to report further on Case 9, previously reported,[1] and to present a photograph of the condition of the implanted testes taken three months after the operation.



Condition of implanted testes three months after operation.

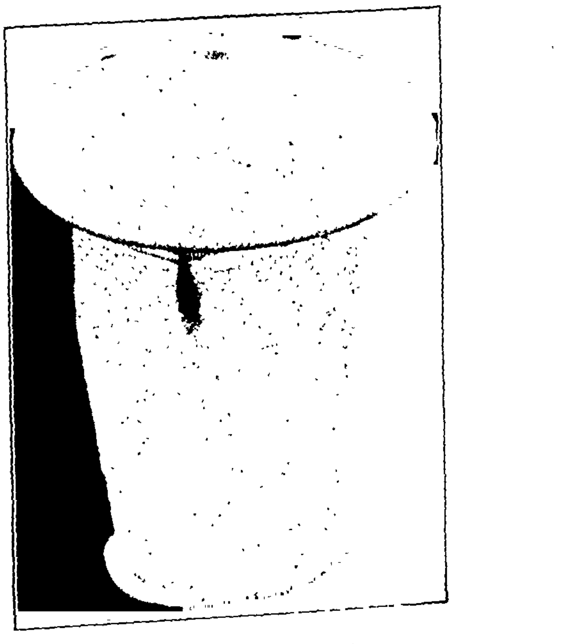
It will be recalled that the glands were taken from the body of a negro who had been hanged for murder, and implanted in the scrotum of a white moron, apparently with remarkable results. Supplementing his previous report, Dr. Stanley writes under the date of February 11, about five months after the operation:

"The testicles in the case, a report of which I gave you, have since atrophied very little, and the patient has improved to a great extent. Several days ago he went out to our 'honor camp,' where prisoners are building highways. This camp is about 200 miles distant from the prison, and I shall not have an opportunity to see him until he returns. He is, however, so far improved physically that he is able to do heavy ordinary labor."

A COFFERDAM INTESTINAL RETRACTOR

R. M. Harbin, M.D., Rome, Ga.

This inexpensive retractor is made in the form of a truncated cone by sewing a section of stocking around pliable copper rings. A dozen or more of different sizes will be found useful in the isolation of infected areas, in reaching inaccessible sources of hemorrhage and facilitating suturing without heavy packing and in searching for lesions causing intestinal obstruction.



Cofferdam intestinal retractor.

RUPTURE OF A HYPERTROPHIC SPLEEN BY INDIRECT VIOLENCE

Maurice P. Rogers, M.D., Rockford, Ill.

REPORT OF CASE

H. P. S., aged 68, a laborer, was admitted to Rockford Hospital, Nov. 26, 1918, stating that about one hour previously he had fallen into a ditch about 7 feet deep, striking his chest on the rim of the ditch.

At the time of his examination he complained of severe cramplike pain in the left upper quadrant of his abdomen. Slight contusions were found over the right upper thorax. The patient complained of severe tenderness on pressure over nearly the entire abdomen but more pronounced to the left of the umbilicus. There was a marked dulness extending into the flank and nearly to the midline. The pulse was 68; respiration, 20; temperature, 98.6; the urine was negative. Blood examination revealed: erythrocytes, 4,000,000; hemaglobin, 80 per cent.; leukocytes, 9,000. The patient's general condition seemed to be very good.

Under local anesthesia a high left rectus incision was made and on piercing the peritoneum large quantities of dark fluid blood poured through the incision. The patient was then anesthetized with ether and a thorough exploration of the upper abdomen was made. Almost immediately a very large spleen was exposed. On palpation a rupture about 6 cm. in length by 4 cm. in depth was exposed just opposite the hilum. The spleen itself was approximately 24 cm. in length, 12 cm. in width by 6 cm. in thickness and was densely adherent to the posterior parietal peritoneum. It was impossible, because of these dense adhesions, to draw the spleen into the incision without undue violence; consequently a wide gauze pack was pressed firmly into the site of the rupture and brought out through the abdominal incision. The pack was removed on the fifth day and the patient went on to an uneventful operative recovery.

On subsequent inquiry it was ascertained that the patient had had malaria about thirty years previously and that he occasionally still had recurrences of chills and fever.

I believe that we have here a case of rupture of the spleen by indirect violence, since the organ was firmly adherent posteriorly while at its anterior margin it was comparatively free. The patient stated emphatically that he did not strike his abdomen in falling, nor was there any external evidence of violence.

226 South Main Street.

HEMORRHAGE OF THE NEW-BORN—BLOOD TRANSFUSION VIA THE LONGITUDINAL SINUS—RECOVERY

Harry Lowenburg, A.M., M.D., Philadelphia
Pediatrist to the Mount Sinai and Jewish Hospitals, Philadelphia

Baby H., a girl, 2 days old, was admitted to my service at the Mount Sinai Hospital, March 5, 1919, bleeding profusely from mouth, nose and rectum. There was nothing in either the family or the obstetric history which would suggest an etiologic factor. The attending physician, Dr. Charles Mazer, reported that the symptoms were inaugurated by hematemesis on the second day after delivery. The infant was in a weakened state and very pale. The cause of the bleeding was indeterminable. Over the telephone I instructed the intern to administer 10 c.c. of normal horse serum. This was done and, in addition, the infant received some physiologic sodium chlorid solution subcutaneously. I saw the baby the following day. It was still bleeding profusely from rectum and mouth. An examination of the mouth and nose was made by Dr. Arthur W. Watson, who was unable either to discover the cause or to suggest any local therapeutic measure. The patient appeared to be in a moribund state. The skin surface was blanched, the patient appearing to be exsanguinated; the respirations were rapid, shallow and irregular; pulse was accelerated and weak. The heart sounds were rather strong; the temperature was 102. The infant was apparently stuporous. Dissolution seemed to be a matter of minutes. Immediate blood transfusion was decided to be the only means of saving the child's life. The operation was undertaken by Dr. A. I. Rubenstone and myself. It was determined to inject the blood directly into the longitudinal sinus via the posterior angle of the anterior fontanel. The infant was removed to the operating room, the head shaved and iodin applied over the fontanel. About 80 c.c. of whole human blood were transferred from the donor to the infant directly into the sinus.

During the operation, which was concluded as quickly as possible, the patient ceased to breathe and was thought to be dead. Feeble heart sounds were, however, still audible. Eighty c.c. more of blood were injected directly under the skin of the abdomen. Artificial respiration was inaugurated, and after several gasps the respiratory function was established, but it was performed feebly. A bad prognosis was given. However, the color of the baby appeared better and bleeding ceased almost immediately. A second transfusion was contemplated, but proved to be unnecessary, as the general condition and color and weight improved with no other treatment than a properly adjusted artificial food mixture. For a short time the infant ran a somewhat irregular temperature, probably owing to the presence of foreign protein. No rashes, however, developed.

The following blood examinations were made:

March 5, 1919: hemoglobin (Von Fleischl), 20 per cent.; red blood cells, 1,400,000; white blood cells, 12,000; polymorphonuclears, 60 per cent.; small mononuclears, 39 per cent.; large mononuclears, 1 per cent.

March 21, 1919: hemoglobin, 65 per cent.; red blood cells, 2,360,000; white blood cells, 10,000; the differential count was of no interest.

April 1, 1919: hemoglobin, 80 per cent.; red blood cells, 3,600,000; white blood cells, 8,200.

2011 Chestnut Street.

New and Nonofficial Remedies

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application. W. A. Puckner, Secretary.

ANTIMENINGOCOCCUS SERUM.—(See N. N. R., 1919, p. *270.*)

The Gilliland Laboratories, Ambler, Pa.

Antimeningococcic Serum (Combined Type).—Marketed in ampule packages containing respectively 15 and 30 Cc. also in aseptic glass cylinders containing respectively 15 and 30 Cc. with sterile needle, stylet, and attachments for intraspinal administration.

Dosage: The recommended intraspinal dosage for the treatment of epidemic cerebrospinal meningitis is 5 to 15 Cc. for a child, and 30 Cc. or more for an adult.

Epilepsy Statistics.—Only 3.5 per cent. of epileptics in the United States are cared for in institutions; 200,000 persons in the United States suffer from epilepsy. Only thirteen states have colonies for the care of epileptics. They care for 7,000 patients. Of 1,000 cases studied, one in every three cannot write; one in every four can read and write; only 340 have a common school education; thirty-two have attended night school; four have attended college. Of 500 men studied, one in twenty-five had hemiplegia; of 500 women, one in thirteen had hemiplegia. The most frequent abnormality found at necropsy at both Craig Colony and Monson State Hospital (Mass.) was dilated lateral ventricles. Abnormalities in the pineal gland and the pituitary body have been met with very frequently in the Monson necropsies. Mental deterioration in epileptics is often in direct proportion to the frequency and severity of the convulsions. Proper food, regulated work and routine life lessen the frequency of the convulsions and postpone dementia.—Bull. Mass. Commission of Mental Dis., July, 1918.

SATURDAY, MAY 31, 1919

THE BRAIN IN EARLY GROWTH

That the central nervous system occupies a superior position in comparison with other tissues of the body is suggested in various ways. Thus it has long been recognized that during a period of starvation the percentage of loss of weight suffered by the brain is far smaller than that suffered by other organs and tissue masses. There are recorded comparative analyses which indicate that even when the entire body experiences a diminution of size represented by far more than a third of its original weight, the decrease in the weight of the brain rarely amounts to 8 per cent. In fact, in young animals at the period of active growth, the brain weight may actually increase during a severe underfeeding which checks the increment of the organism as a whole.

Another unique feature of the central nervous system is exemplified in the early completion of its fundamental morphologic organization. The most detailed information of such facts has been derived from studies on lower mammals, such as the rat; but there are many reasons for assuming that the results obtained with this species correspond, with due allowance for differences in age and size, to the sequence of changes that proceeds in the human organism. Hence we may refer with some assurance to a recent study by Sugita[1] at the Wistar Institute of Anatomy in Philadelphia on the precocious organization of the cerebral cortex. He informs us that the size of individual cortical nerve cells, the total number of cortical cells, and the thickness of the cortex, all attain nearly their full values at the same time and very early in life (corresponding to the weaning time in some species), after which the maturation of internal structures of the cell body and the nucleus continues. The brain weight and the cortical volume continue to increase even after this stage throughout the postnatal life, though not so rapidly as during the early period. This later growth is due principally to the development of the cell attachments, intercellular tissues (neuroglia tissue and blood vessels), and the ingrowth of axons into the cortex and their myelinization, which together separate the cells from each other and cause an increase in cortical volume.

The facts now established that the cortex of the brain becomes provided very early in life with nearly all of the cellular elements necessary to it at maturity, and that the changes incident to growth are essentially those of enlargement of the cell bodies, growth of axons, and myelinization, help to explain the early completion of cerebral organization. According to Donaldson[2] and Sugita,[3] the human cortex should have attained nearly its full thickness at about the age of 15 months, when cell multiplication and the migration of cells into the cortex have come practically to an end.

Recent evidence further indicates that although underfeeding and partial starvation may retard the growth of the cortical cells in size and the formation of myelinated fibers, the number of neurons remains unmodified.[4] This makes it increasingly more likely that each species has in its nervous system a characteristic number of neurons—a number which is constant within the limits of biologic variation. Hence the somewhat smaller weight and size occasionally found for the brain of undernourished individuals is due to an arrest in the growth and development of the constituent neurons, and not to a decrease in their number.

Donaldson has well represented the significance of such studies on the early development changes in the brain. Commenting on the fact that the cerebral cortex has attained its thickness at 15 months of age so that it must later undergo a large increase in area without any significant change in thickness, he[2] remarks: "All this shows that the important events in the postnatal growth of the nervous system occur early in life, and this in turn emphasizes the paramount importance of favorable conditions during the first three years of childhood."

THE SYSTEMIC EFFECTS OF SEVERE EXPOSURE TO ROENTGEN RAYS

Prolonged exposure to roentgen rays may be followed by a marked general systemic or constitutional reaction as well as by the more familiar epithelial symptoms known as skin burns. The dermatitis of the latter sort was the first of the manifestations to be discovered and described; but it is by no means always the more serious or even the more conspicuous effect. In recent times more particularly, the improved tubes in use have made it possible to administer "massive doses" to structures beneath the skin so that the latter will escape the danger of a burn.

[4] Sugita, N.: Comparative Studies on the Growth of the Cerebral Cortex, VII, On the Influence of Starvation at an Early Age on the Development of the Cerebral Cortex, J. Comparative Neurol. **29**: 177, 1918.

The clinical symptoms of the systemic reaction in the interior of the body resemble somewhat an acute intoxication. They include extreme prostration, together with such gastro-intestinal symptoms as vomiting and diarrhea. Edsall and Pemberton,[1] who were among the first to attempt a scientific elucidation of these constitutional symptoms, regarded them as due to a sudden demand on the organism for the complete disintegration and excretion of a large amount of the products of tissue breakdown. They assume an inability on the part of the organism to accomplish this in these cases, and a consequent "halting of metabolism," resulting in an intoxication produced by incompletely disintegrated tissue remnants.

More recently, Hall and Whipple[2] have conducted highly desirable experimental investigations at the University of California Medical School on the general constitutional reaction which follows prolonged exposure to the roentgen rays of the Coolidge tube. They are inclined to classify the effects under the caption of "nonspecified intoxications," making them comparable with the conditions observed in intestinal obstruction or in acute pancreatitis, for example. Bacteria and specific toxins or antibodies cannot be concerned in the roentgen-ray effects. Conspicuous among the metabolic phenomena is the marked increase in the urinary nitrogen output and also in the nonprotein nitrogen of the blood.

All observers agree that there is increased breakdown of body protein in consequence of severe roentgen-ray treatment. But how is the accumulation of the disintegration products in the blood to be accounted for? Is kidney irritation an accompanying manifestation? Thus far there has been no convincing indication of the existence of a roentgen-ray nephritis. The only abnormality of a gross sort discovered in the more recent investigations is a probable epithelial injury in the intestinal mucosa. Hall and Whipple assert that in the fatal cases the epithelium lining the intestinal crypts may show actual necrosis and invasion of polymorphonuclear leukocytes. They affirm that this epithelium also shows a remarkable speed of autolysis, and may vanish by self-digestion within a few hours postmortem.

If the observations of the California investigators on the sensitiveness of the small intestine to large doses of roentgen rays are correct, the injury noted may serve to explain the general intoxication attended with gastro-intestinal symptoms. Whipple is, further, inclined to correlate the clinical picture of fatal roentgen-ray intoxication with that which he and his co-workers[3] have described as that of acute intestinal obstruction. As he maintains, death may take place at about the same interval after the initial injury or obstruction. Violent gastro-intestinal disturbances dominate the picture in both conditions, and there is every evidence of great tissue injury and increased tissue catabolism. In each case the intestinal epithelium seems to be involved.

What is now known of the effects of the roentgen rays used in therapeutic doses thus seems to justify their designation as a "nonspecific" reaction. It may be that the primary action is on the tissue proteins so as to form cleavage products which are further toxic to the organism; just as in a heat burn, harmful products are found and, being absorbed, induce signs of intoxication. The widespread employment of roentgen-ray therapy forms a sufficient justification for more profound investigation of the metabolic phenomena of the procedure. Only in this way can its dangers and its possible unsuspected "nonspecific" therapeutic potencies be ascertained.

THE PHYSIOLOGY OF STAMMERING

The dictionary defines stammering or stuttering as consisting in making involuntary stops in uttering syllables or words—a halting, defective utterance. Fortunately the time has gone by when any except the most inerudite regard stammering as primarily due to an anatomical defect of the mouth or the throat. It has become clear that the nervous system is in some way responsible. Various systems of overcoming stammering have been introduced with considerable success. The greatest promise of controlling this most embarrassing interruption of speech lies in ascertaining, first of all, precisely what physiologic and psychologic factors enter into and condition its manifestations.

Bluemel[4] has defended the hypothesis that stammering is the result of cerebral congestion. There is reason to believe that such a circulatory disturbance affects speech as readily or even more easily than it does any other activity. The cerebral congestion is assumed, on Bluemel's theory, to blur verbal imagery, especially auditory verbal imagery. A transient auditory amnesia in the auditory speech center makes it "impossible for the stammerer to recall, for the time being, a part or the whole of the word he wishes to speak at the moment he has to say it."

Fundamental in establishing the validity of the views just set forth is the demonstration that cerebral congestion actually occurs in the process of stammering. Every one knows from casual observations that stammering may be induced or accentuated in susceptible persons by emotional states. Such psychic disturbances are, furthermore, demonstrably accompanied by vasomotor changes. Experiments have been reported to show that certain forms of shock, i. e., responses to unexpected psychic stimuli, are always accompanied by vasoconstriction in the peripheral blood vessels and by vasodilatation in the brain. The evidence has been obtained by studying the circulation simultaneously in a limb and through a trephine wound in the skull. Postulating that the interrelation between peripheral vasoconstriction and cerebral vasodilatation has a more general validity, Robbins[2] has studied the peripheral circulatory changes in stammerers at the Harvard Psychological Laboratory. Comparing them with normal persons he found in stammerers approximately the same vasoconstriction at the periphery as has been recorded for the sudden stimuli popularly called shocks. Thus, when an unexpected sound, a harsh command, or a cause of fright initiated the familiar inability at verbal expression, plethysmographic records of the finger or arm invariably showed a vasoconstriction. Robbins summarizes: "Long stimuli are accompanied by greater vasoconstriction and slower recovery than are short stimuli. . . . The more intense the stimulus and the more unexpected the stimulus, the greater is the vasoconstriction, the more rapid the vasoconstriction and the slower the recovery. . . . The greater the vasoconstriction, the more is verbal imagery impaired. . . . Those subjects who experience the greatest vasoconstriction during shock and stammering also require the longest time for recovery." Robbins' records show that "peripheral vasoconstriction continues throughout the stammering interval; if any vasomotor change accompanies normal speech it is vasodilatation in a large majority of periods." Furthermore, "fear of stammering with no attempt at speaking produces vasoconstriction in the periphery as does actual stammering. Stammerers cannot speak without hesitancy during vasoconstriction."

[3] Whipple, Cooke and Stearns: J. Exper. M. **25**: 479, 1917.

[4] Bluemel, C. S.: Stammering and Cognate Defects of Speech, New York, 1913.

The deduction, from these experiments, that stammering, like fright and other forms of "mental shock," is accompanied by cerebral congestion has a high degree of probability but still requires actual demonstration. A satisfactory solution could doubtless be found if it were possible to conduct observations, as Robbins hopes to do, directly on the brain of some stammerer who has been trephined. Meanwhile we may recall, by way of analogy that persons often "lose their heads" through fright, becoming unable during the cerebral congestion to perform muscular efforts of a variety of sorts with customary efficiency. In a practical way it may be helpful to bear in mind the following logic of Robbins:

> As vowels are governed primarily by auditory imagery they are the stammerers' bugbears. The stammerer prolongs continuous consonants for seconds and repeats closed consonants over and over until able to recall the vowel that follows. The more the vowel is inhibited, the harder he forces out the preceding consonant, the more he thereby increases cerebral congestion, the more impossible it becomes to recall the vowel, and the worse he stammers. Many stammerers are thus led to believe that their trouble lies with the consonants they thus overdo and, by concentrating their mind on trying to force out these consonants, they keep the mind from recalling the vowel which fails to come promptly, and thus they increase their stammering.

THE STUDY OF BACTERIAL NUTRITION

The bacteria have at length acquired a position in the domain of research which takes them beyond the elementary stage of systematic classification. It is no longer fashionable or profitable merely to arrange the different micro-organisms in an orderly scheme whereby they can be identified; nor does the young science of bacteriology content itself solely with the search for microbial agents of disease or the mere descriptions of varied bacterial floras. Biologic chemistry has made an inroad into the field, bringing along the modern conceptions that have enhanced the study of the functions of living organisms. Hence one reads today of studies in bacterial metabolism.

It has already been pointed out in The Journal[1] that a great advantage would be gained if the nutrient needs and the metabolic functions of bacteria were better known. Given the possibility of regulating the composition of culture mediums in accord with the precise needs of the organism, it would no longer be necessary to depend on such uncertain products as imported "peptone" of unknown composition, or crude decoctions of tissues of indefinable make-up for the successful cultivation and identification of bacteria. It is now understood, particularly through the studies of Rettger[2] and his pupils at Yale University, that purified unaltered proteins are resistant to bacterial attack, probably because their complex structure renders them unfit for immediate utilization. Not so, however, in the case of simpler nitrogenous compounds. Recent investigations[3] indicate that many species of bacteria are able to synthesize their own protoplasm from a very simple amino-acid like glycocoll, and thus utilize it as readily as more complex representatives, such as tryptophan, on which animal organisms are so dependent. A number of organisms have already been shown to be capable of passing through many successive cultures in an amino-acid medium without any diminution of luxuriance or rapidity of development. Most of them can even initiate development as readily on diammonium phosphate as on the amino compounds. Combinations of the latter apparently possess little advantage over any one of the individual amino-acids.

S.: Further Studies on Bacterial Nutrition: The Utilization of Proteid and Nonproteid Nitrogen, J. Bacteriol. **1**: 16, 1916.

[3] For a review of the subject, compare Koser, S. A., and Rettger, L. F.: Studies in Bacterial Nutrition: The Utilization of Nitrogenous Compounds of Definite Chemical Composition, J. Infect. Dis. **24**: 301 (April) 1919.

Such researches, in a field in which scarcely more than the beginning has yet been made, greatly simplify the problem of the accurate study of bacterial nutrition. They by no means demonstrate, however, that the character of the nutrition, that is, the environment, of the micro-organism has no influence on the nature of the bacteria. Diehl[4] of the Department of Bacteriology at the University of Minnesota, has recently reported that on a medium containing no organic nitrogen, proteolytic enzymes are not formed by bacteria. The results with mediums containing amino-acids are varied. Diehl contends that the proteolytic enzymes are not preformed in the bacterial cell but are dependent on the nature of the substrate on which it grows. They are conceived to be specific for the amino-acids that go to make up proteins. If these speculations prove to be correct, they may help to explain the supposed occasional aberrant appearance of strains of bacteria—an irregularity which in the light of the new hypothesis might never appear if the chemical composition of the nutrient medium were always identical. Furthermore, as Diehl says, such differences in nutrient environment may help to account for many of the unverified "new strains" of bacteria, the differentiation of which is based on some minor phase of their action on culture mediums.

Current Comment

THE FUNCTIONS OF THE CELL NUCLEUS

Ever since the first description of the nucleus of a cell by Robert Brown in 1831, morphologists have been inquisitive regarding its purpose. That it is of fundamental importance, nobody doubts. Unquestionably the nucleus forms a part of the physical mechanism of inheritance. As to its rôle in the everyday performances of the living cell, it has been conjectured that the nucleus is concerned with the growth and synthesis of new protoplasm, or again that it is the center of the all-important oxidative processes of the organism which are now recognized to proceed in the cells rather than the circulating fluids of the body. Commenting on the evidence respecting these two hypotheses, Lynch[5] has remarked that the assumption that the organ which is farthest removed from the supply of oxygen is the organ of oxidation is not probable. In experiments conducted in the physiologic laboratory of the Johns Hopkins University, he has compared the behavior of cells (amebas) from which the nucleus has been removed with those containing this structure intact. Lynch observed that the enucleated structure may move, respire, digest, respond to stimuli, and exhibit any activity that is dependent solely on catabolic or destructive processes of protoplasm. The group of phenomena which it never shows are those of growth and of regeneration and division. As the phenomena of growth are essentially those of organic synthesis, he concludes that the dependence of growth on the nucleus implies the dependence of organic synthesis on the nucleus. Such speculations cannot fail to be engrossing when one stops to recall that our entire body is, after all, essentially a myriad of nucleated cells. For pathology it is highly important to understand the possibilities of function in the various parts of cells, so that the efforts to prevent abnormal cellular metamorphoses may be more intelligently directed.

CYANOSIS IN INFLUENZA

Cyanosis has been a constant and striking manifestation in the recent epidemic of influenza and bronchopneumonia. It occurs early in the disease and is apparently not associated with enlargement of the right heart, even in advanced cases. The emphysema of the lungs which develops as the lung involvement extends may be a causative factor in some instances but apparently not in the early stages. As the color of the skin suggests a lack of oxygen, artificial respiration, as well as oxygen inhalations, have been tried with the view of relieving the cyanosis but without success. Harrop[1] has studied the behavior of the blood of influenza infections toward oxygen. He found the oxygen content and oxygen unsaturation to give normal values in uncomplicated cases of influenza. The oxygen unsaturation of the blood is a measure of that part of the hemoglobin whose oxygen-combining power is not fully saturated. It is determined by obtaining the difference between the oxygen content of venous blood and the total oxygen-combining power of the hemoglobin. Harrop says also that "in none of the cases of bronchopneumonia which recovered, and not until terminal collapse in fatal cases, has the venous oxygen content or the amount of oxygen unsaturation been abnormal." The values seemed to be independent of the temperature, the respiration and the extent of lung involvement. These results would seem to explain the uselessness of oxygen inhalation in these cases. Attention has also been directed to methemoglobin since the presence of this substance in the blood is a well-known cause of cyanosis. It is known that methemoglobin contains the same amount of oxygen as hemoglobin, but that it is combined differently, forming a more stable compound which cannot be dissociated by a vacuum. On this account, methemoglobin is not able to act as an oxygen carrier. While the observations of Harrop indicate that the oxygen content and oxygen unsaturation give normal values in influenza, the question still remains whether or not the blood has undergone any chemical change which decreases the oxygen carrying power. In an endeavor to answer this question for pneumonia Butterfield and Peabody[2] demonstrated that methemoglobin is formed when the pneumococcus is grown in

Medical Mobilization and the War

Deaths in the Army

The *United States Bulletin* of May 19, published the following statement regarding the number of deaths in the United States Army, from the beginning of the war to the various dates recorded:

	From Disease	Battle	Other Injury	Total
In United States, to April 18, 1919.....	33,537	......	822	35,359
In France, to April 23, 1919...........	22,996	48,068	4,536	75,600
In Archangel, Russia, to April 21, 1919.	67	100	4	171
In Siberia, to April 18, 1919..........	39	......	10	49

Wounded Slightly

In the issue of the *U. S. Bulletin* of May 8, it was reported that the following medical officers had been wounded slightly: Malcolm Newlon, Lieut., M. C., U. S. Army, Lincoln, Kan., and Lacy W. Corbett, Lieut., M. C., U. S. Army, Bishopville, S. C.

Influenza on Transport

On board the *Martha Washington,* which sailed from Pauillac, France, May 7, and arrived in Newport News, Va., May 19, with 3,013 soldiers, fifty-seven cases of influenza developed and the entire passenger list was placed in isolation for five days.

Medals of Honor Awarded

Frederick P. Reynolds, Col., M. C., U. S. Army, and Royal Reynolds, Lieut.-Col., M. C., U. S. Army, have been awarded the French Medaille d'Honneur das Epidemies at the American Red Cross Hospital No. 112, Auteuil, France.

Distinguished Service Order Given

George P. O'Malley, Capt., M. C., U. S. Army, Cleveland, was recently awarded the Distinguished Service Order by the British government.

Awards of Distinguished Service Cross

By direction of the President, the distinguished service cross was awarded by the commanding general, American Expeditionary Forces, for extraordinary heroism in action in Europe, to the following named officers and enlisted men of the American Expeditionary Forces:

THOMAS B. GOLD, first lieutenant, Medical Corps, 119th Infantry, Lawndale, S. C. For extraordinary heroism in action near Busigny, France, Oct. 9, 1918, and Mazinghien, France, Oct. 18-19, 1918. During the attack of October 9, he established his first aid post in a roadside shrine up with the front line, where he rendered valuable service to the wounded. On another occasion he established alone a post close to the front line, where he again gave treatment until the heavy fire of the enemy forced him to withdraw. During the advance of October 18-19, he established another front line post under the enemy fire and thus saved the lives of many of the troops.

GEORGE W. CRILE, Lieut.-Col., M. C., U. S. Army, commanding the Lakeside Hospital Unit, Cleveland, and later consulting specialist for the American Expeditionary Forces. The citation states: "By his skilled researches and discoveries he saved the lives of many wounded soldiers. His tireless efforts to devise new methods of treatment to prevent infection and mental shock revolutionized army surgery and met with great success."

American Red Cross Mission Arrives in Siberia

The American Red Cross Siberian Commission arrived in Vladivostok on April 28. Among the American members are Drs. J. Rudis-Jicinsky, V. Anyz, G. Cepelka, Chicago, and G. W. Davis, Kansas City. It is under the leadership of Dr. Teusler. The commission consists of four physicians, fourteen nurses and a pharmacist. Drs. Rudis-Jicinsky and Anyz have been detached and sent to Omsk to fight typhus fever and to aid the Czecho-Slovaks along the Siberian railway.

French Decorate Naval Officers

For bravery in action with the United States forces in the Champaign offensive near Rheims, in October, 1918, Lieut.-Com. Joel T. Boone, M. C., U. S. Navy, was decorated, April 28, by the acting secretary of the Navy, with the Croix de Guerre with Palm. The decoration followed congratulatory expression of appreciation by the acting secretary and Surg.-Gen. William C. Braisted, U. S. Navy. Commander Boone's remarkable war record is shown by the following summary of his citations and awards: cited for American Distinguished Service Cross, in June in the Belleau Woods action; in September at Thiaucourt in the St. Mihiel offensive, and October in the Champagne offensive. He was cited for French decoration in July in Soissons offensive, and in October in the Champagne offensive. He was cited for Medal of Honor in December in the Soissons action and on account of the general revise of his acts. He was cited in Divisional Orders No. 44, Second Division, in July for acts in Belleau Woods. The citation for which the French decoration was awarded Commander Boone was as follows: "Between Oct. 2 and 10, 1918, this officer was constantly circulating among the attacking companies, directing with success and the greatest coolness the evacuation of the wounded from the battlefield under heavy artillery and machine gun fire. He showed at all times an utter disregard of personal safety, his fearless behavior being a splendid example to those about him. This work was maintained over a period of nine days until the last relief had taken place."

HONORABLE DISCHARGES, MEDICAL CORPS, U. S. ARMY

Note.—In the following list, L. signifies lieutenant; C., captain; M., major; L. C., lieutenant-colonel; Col., colonel, and B. G., brigadier-general.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

ARKANSAS

New State Officers.—The forty-third annual meeting of the Arkansas Medical Society was held in Little Rock, May 20 to 22, under the presidency of Dr. Edward F. Ellis, Fayetteville, and the following officers were elected: president, Dr. George S. Brown, Conway; vice presidents, Drs. Charles E. Kitchens, Dequeen; Aaron L. Carmichael, Little Rock, and R. E. Cooksey, Magnolia; secretary, Dr. Clinton P. Meriwether, Little Rock (reelected); treasurer, Dr. William R. Bathurst, Little Rock (reelected).

CALIFORNIA

May Return Annual Fee.—The governor has just approved a bill passed by the legislature authorizing the State Board of Medical Examiners to return annual fees to physicians collected during the time they were in the national service.

Legislature Reverses Itself.—A peculiar situation has arisen in regard to granting osteopaths the right to use the hypodermic syringe in administering local anesthetics. Both houses of the legislature passed House Bill No. 928, granting this right, and also Senate Bill No. 604, forbidding such practice by osteopaths. The two bills had been introduced as companion measures. The decision now rests with the governor as to which shall become a law.

CONNECTICUT

Annual Meeting of State Society.—At the annual meeting of the Connecticut State Medical Society held in Bridgeport, May 21 and 22, the following officers were elected: president, Dr. Charles B. Graves, New London; vice presidents, Drs. George H. Noxon, Darien, and Frank H. Wheeler, New Haven; secretary, Dr. John E. Lane, New Haven (reelected); treasurer, Dr. Phineas H. Ingalls, Hartford; editor of the proceedings, Dr. James F. Rogers, New Haven (reelected). The next meeting will be held at New Haven, May 19 and 20, 1920.

Medical Library Enlarged.—Yale University School of Medicine has enlarged its medical library, providing more space for books and for the reading room. There are now 26,000 volumes in the library, including 14,000 bound volumes of medical journals and society transactions. There are over 250 medical periodicals, including both American and European journals. The library contains the "Index Medicus," the "Surgeon-General's Catalogue," and the "Quarterly Cumulative Index." A part of the library was donated to the medical school by the New Haven Medical Society.

DISTRICT OF COLUMBIA

Emergency Hospital.—Dr. William P. Carr has relinquished the post of chief attending surgeon, having been made consulting surgeon. Dr. James F. Mitchell has been appointed chief attending surgeon.

New Treasurer for Medical Society.—Dr. Charles W. Franzoni, for over forty-six years treasurer of the Medical Society of the District of Columbia, has resigned on account of the infirmities of age. The society accepted the resignation but made Dr. Franzoni treasurer emeritus and continued the honorarium he had formerly received. Dr. Edward G. Seibert was elected treasurer.

GEORGIA

Practice Act Amended.—The Georgia legislature has passed amendments to the medical practice act increasing the requirement of preliminary education in the state to two years of college work in and after the session of 1919-1920; providing for the recognition of certificates granted by the National Board of Medical Examiners and providing for the revocation of the license of any physician convicted of violating the Harrison Narcotic Law.

Personal.—Dr. Charles D. Cleghorn, superintendent of the Macon Hospital, has resigned and has been succeeded by Mr. L. C. Brown.——Dr. Charles L. Williams, who has been in charge of the health department of Macon since the location of Camp Wheeler, has moved to Charleston, S. C., and before leaving was presented with a gold watch and chain by the mayor and council of Macon.——Dr. Mather M. McCord, Rome, health officer of Floyd County, has resigned, to take effect July 1.

ILLINOIS

Special Health Edition of Urbana Daily Courier.—This paper, published in Urbana, Ill., the seat of the state university, issued a special health edition, Monday, May 12, the first day of the "clean-up" week. A six-page supplement is devoted entirely to this campaign, and the articles contained are written by such persons as the chairman of the sanitation committee, president of the Association of Commerce of Urbana, the mayor of the city, county superintendent of schools, members of the University faculties, and many others.

New State Officers.—At the sixty-sixth annual meeting of the Illinois State Medical Society held in Peoria, May 22, under the presidency of Dr. Edward W. Fiegenbaum, Edwardsville, the following officers were elected: President, Dr. J. Warren Van Derslice, Oak Park; president-elect, Dr. W .F. Brinsted, Cairo; vice presidents, Drs. George H. Weber, Peoria, and Clara P. Seippel, Chicago; secretary, Dr. Wilbur H. Gilmore, Mount Vernon (reelected); treasurer, Dr. A. J. Markley, Belvidere (reelected). The next meeting will be held in Rockford.

New Officers.—At the annual meeting of the Knox County Medical Society, held in Galesburg, May 8, Dr. Charles B. Horrell, Galesburg, was elected president; Dr. Clark E. Weir, Abingdon, vice president, and Dr. George S. Bower, Galesburg, secretary (reelected). Of the forty-four members of the society, seventeen were in the military service and eighteen were members of draft boards.——At the annual meeting of the Elgin Physicians' Club, May 5, Dr. Ralph T. Hinton, Elgin, was elected president; Dr. George F. Ruppert, Elgin, vice president, and Dr. Sallie Y. Howell, Elgin, was reelected secretary-treasurer.

Chicago

Personal.—Harry D. Orr, Col., and Daniel W. Rogers, Lieut.-Col., M. C., U. S. Army, have returned from Europe with the Thirty-Third Division.

Sachs Memorial Tablet.—A memorial tablet will be dedicated at the grave of Dr. Theodore B. Sachs, at the Edwards Sanatorium, Naperville, June 1, at 4 p. m. Addresses will be delivered by Drs. Robert H. Babcock, Ethan Allen Gray, and Mrs. M. L. Aren.

LOUISIANA

Six Clinics for Women.—Six new clinics of the Lying-In Hospital Dispensary, New Orleans, for women expecting confinement, are to be opened in various parts of the city, by Dr. Jacob W. Newman, New Orleans, director of the institution.

Personal.—Dr. Joseph A. Danna, New Orleans, who commanded the Loyola Hospital Unit in Italy and recently returned to the United States, has been elected a member of the Board of Directors of the City Bank and Trust Company, New Orleans.——Dr. Fred W. Gaulden, New Orleans, was elected president of the Supreme Council of the Catholic Knights of America at its meeting in St. Louis, May 16.

New Officers.—At the annual meeting of the Louisiana State Medical Society held at Shreveport, April 8 to 10, under the presidency of Dr. Wilkes H. Knolle, New Orleans, the following officers were elected: President, Dr. Eugene L. Henry, Lecompte; vice presidents, Drs. Courtland P. Gray, Monroe; Sidney C. Barrow, Shreveport; Theodore J. Dimitry, New Orleans; secretary-treasurer, Dr. Everard W. Mahler, New Orleans.

MARYLAND

New Officers.—The twenty-second anniversary of the Baltimore County Medical Association was celebrated May 21, at the Hotel Rennert, Baltimore. The officers of the organization are: president, Dr. Frank W. Keating, Owings Mills; vice president, Dr. John W. Harrison, Middleriver; secretary-treasurer, Dr. Alfred T. Gundry, Catonsville.

Health Ordinance for Hagerstown Fails.—A health ordinance, drafted by a committee appointed by seven charitable and social bodies to provide for a city health officer for Hagerstown, failed, as it was held that the appointment of such an officer, created by the proposed ordinance, was vested in a committee of persons who were not municipal officers. The city attorney has been instructed to draft a health ordinance that will be practical. The committee appointed by the charitable and health organizations was also asked to prepare a new ordinance.

Personal.—Col. A. Depage, the Belgian surgeon, was a guest during this week of the Baltimore committee of the American Medical Association, composed of Drs. John M. T. Finney, Lewellys F. Barker, Archibald C. Harrison, Hugh H. Young and Thomas S. Cullen. Colonel Depage lectured at the Johns Hopkins Hospital on "Hospital Work at the Front," illustrated with lantern slides, on May 21.——Asst. Surg.-Gen. Henry R. Carter, U. S. P. H. S., who has been seriously ill with influenza and pneumonia while on a southern detail, has recovered sufficiently to return to his station, at the U. S. Marine Hospital, Baltimore.

MASSACHUSETTS

Personal.—Dr. Walter D. Berry, assistant superintendent of the Gardner State Colony for the Insane has been appointed resident physician and surgeon of the Connecticut Reformatory, Cheshire.

Asks Increased Pay for Coroners.—Dr. George B. Magrath, Boston, medical examiner (coroner) for Suffolk County, has asked the committee on counties to report favorably on the bill calling for increased salaries of medical examiners (coroners) in Suffolk, from $4,000 to $5,000.

New Officers.—At the annual meeting of the Norfolk District Medical Society held in Boston, May 13, Dr. Francis P. Denny, Brookline, was elected president; Dr. George W. Winchester, vice president; Dr. Bradford Kent, secretary, and Dr. George W. Kaan, treasurer, all of Boston.

MICHIGAN

Personal.—Dr. Fred R. Belknap, Benton Harbor, underwent operation, May 7, at Mercy Hospital, Benton Harbor. ——Dr. William De Kleine has been reelected health officer of Flint.

Physicians Freed by Jury.—In the cases of Drs. Ezra L. Covey, Homer, and Lewis M. Carey, Pontiac, charged with having performed an illegal operation on a Pontiac woman, thereby causing the death of her infant, the circuit court jury returned a verdict of acquittal, May 14.

Hospital Shortage.—The Detroit *Free Press*, in an editorial, May 19, on the inadequacy of the hospital facilities of Detroit, citing the report of Dr. Warren L. Babcock, Detroit, chairman of the hospitals committee of the Community Union, that the city is about 50 per cent., or 2,700 beds, short of its needs.

Municipal Medical School in Detroit.—The Detroit College of Medicine and Surgery is now a municipal institution, having been placed under city control in June, 1918. A bill has just been passed by the Michigan legislature ratifying this action and authorizing the board of education of Detroit to conduct the medical school as a part of its educational system.

State Board Appointments.—Dr. Richard M. Olin, Lansing, secretary of the state health board has been appointed state health commissioner under the new Moore bill.——Drs. James G. Turner, Houghton, and Guy L. Kiefer, Detroit, have been appointed members of the advisory health council for the six year term, and Dr. Clyde C. Slemons, Grand Rapids, Frank M. Gowdy, St. Joseph, for the four-year term. The fifth member of the council, who must be an attorney, has not been appointed.

MINNESOTA

Cleared of Charges.—At the meeting of the board of trustees of the Soldiers' Home, Minneapolis, May 13, Dr. Thomas C. Clark, superintendent of the home, was exonerated of the charges of neglect which has been made against him by wives of certain inmates of the institution.

Personal.—Dr. Henry M. Bracken, secretary of the state board of health, St. Paul, resigned, May 12, and has been appointed supervisor of District No. 10, of the United States Public Health Service, which comprises Minnesota, North Dakota, South Dakota and Montana. He will hold commission as surgeon of the Reserve Corps, U. S. P. H. S. His headquarters will be in St. Paul, and his duties will be the organization and administration of agencies for the care of war risk patients.—Dr. William B. Wright, Jr., St. Paul, has been appointed superintendent of the Rood Hospital, Hibbing. ——Dr. Mabelle S. Ulrich, Minneapolis, has been appointed a member of the board of public welfare.——At the meeting for organization of the Cottonwood County Health Association at Windom, April 30, Dr. Ludwig L. Sogge was elected president.

NEW HAMPSHIRE

New State Officers.—At the annual meeting of the New Hampshire Medical Society, May 15, the following officers were elected: president, Dr. Augustus W. Shea, Nashua; vice president, Dr. Alpha H. Harriman, Laconia.

President of State Board Dies.—Dr. Albert S. Wetherell, Exeter, president of the state board of pharmacy, aged 68; for many years chairman of the public and state executive committees, a member of the house of representatives in 1893 and 1895 and of the senate in 1901, died at the Cottage Hospital, Exeter, April 1.

NEBRASKA

State Officers for 1920.—At the fifty-first annual meeting of the Nebraska State Medical Association, held in Lincoln, May 20 to 22, under the presidency of Dr. John M. Banister, Omaha, the following officers were elected: president, Dr. H. Winnett Orr, Lincoln; vice presidents, Drs. George H. Brash, Beatrice, and Adolph Sachs, Omaha.

Personal.—Dr. Ernest T. Manning, commissioner of health of Omaha, has resigned.——Dr. Elizabeth P. M. Hohl, McCook, has been elected grand medical examiner for Nebraska of the Order of Degree of Honor.——Dr. Clifford A. Lutgen, Auburn, who was operated on in Omaha for appendicitis recently, is making rapid progress toward recovery.

NEW YORK

Personal.—The council of New York University has voted unanimously to confer on Dr. William G. Bissell, Buffalo, the honorary degree of Doctor of Public Health, at the coming commencement, June 11.

Lethargic Encephalitis.—In view of the desirability of making pathologic and etiologic studies of fatal cases of lethargic encephalitis, the state department of health requests that when feasible, specimens of the brain and particularly the medulla and pons, and when possible of the spinal cord, be sent promptly to the division of laboratories of the New York state department of health. The specimens should be placed in an abundance of 10 per cent. liquor formaldehyd after small portions of the medulla and pons have been excised and put in a mixture of half glycerin and water. It is also requested that a brief history of the case accompany the specimens.

New Officers.—At the annual meeting of the Medical Society of the State of New York held in Syracuse, May 6 to 9, under the presidency of Dr. Thomas H. Halsted, Syracuse, New York was chosen as the place of meeting for 1920, and the following officers were elected: President, Dr. Grant C. Madill, Ogdensburg; vice presidents, Drs. Dwight H. Murray, Syracuse; William M. Dunning, New York City, and George W. Cottis, Jamestown; secretary, Dr. Floyd M. Crandall, New York (reelected); assistant secretary, Dr. Edward L. Hunt, New York; treasurer, Dr. Harlow Brooks, New York; assistant treasurer, Dr. Thomas C. Chalmers, Queens' County.

New Section Officers.—At the annual meeting of the Medical Society of the State of New York, held in Syracuse, May 5 to 8, the following sectional officers were appointed: section on pediatrics: Dr. Alfred C. Mercer, Syracuse, chairman; Dr. Godfrey R. Pisek, New York City, vice chairman, and Dr. Robert Sloan, Utica, secretary; section on medicine: Dr. Claude C. Lytle, Utica, chairman; Dr. Ledra Heazlit, Auburn, secretary; section on public health: Dr. Paul B. Brooks, Albany, chairman; Arthur D. Jaques, Lynbrook and Rockville Center, secretary; and section on eye, ear, nose and throat: Dr. Arthur J. Bedell, Albany, chairman, and Dr. Irving W. Voorhees, New York City, secretary.

New York City

Treasury Takes Brooklyn Hospital.—The Norwegian Hospital at Fourth Avenue and Forty-Sixth Street, Brooklyn, has been taken over by the Treasury Department. The institution is to be used for caring for men covered by the War Insurance Act whom the Army refuses to discharge from service until cured.

Memorial Hospital for Queens.—The Citizens Committee of the Borough of Queens has announced plans for the erection of hospital buildings in connection with St. Mary's and the Jamaica Hospitals in memory of the soldiers of the Borough of Queens who lost their lives in the war. The estimated cost of the proposed buildings is $500,000 which will be raised by a public drive throughout the borough. These buildings will be equipped with 100 beds each and with laboratories, clinics, ambulances and other hospital facilities.

Auditorium Building for Mount Sinai Hospital.—The Mount Sinai Hospital has received a gift of $150,000 from Mr. and Mrs. George Blumenthal for the erection of an auditorium building on the hospital grounds at Nintey-Ninth Street east of Fifth Avenue. Besides a large auditorium which will be devoted to the educational work of the hospital, the Mount Sinai Training School for Nurses, and the social service department, the new building will house a new roentgen-ray department. The building is to be erected as a memorial to George Blumenthal, Jr. The Blumenthal Auditorium, as the new building is to be known, will be the sixteenth building in the Mount Sinai group.

Faculty Appointments at Columbia.—The following appointments and promotions at the College of Physicians and Surgeons of the City of New York are announced by the trustees of Columbia University: Dr. William E. Studdiford, professor of obstetrics and gynecology, to succeed Dr. Edward B. Cragin, deceased; Dr. Allen O. Whipple, associate in surgery, to be assistant professor of pathology; Dr. Benjamin P. Farrell, instructor in orthopedic surgery, to be assistant professor in the same branch; Dr. Louis Casamajor, associate professor of neurology, to be professor of neurology, and Oliver S. Strong, Ph.D., assistant professor of neurology, to be associate professor of neurology.

OKLAHOMA

New Officers.—At the annual meeting of the Oklahoma State Medical Association held in Muskogee, May 20 to 22 under the presidency of Dr. Lewis J. Moorman, Oklahoma City, the following officers were elected: president-elect, Dr. John W. Duke, Guthrie; vice presidents, Drs. Jackson Brashear, Lawton; General Pinnell, Miami, and John A. Hatchett, El Reno. Oklahoma City was selected as the place of meeting for 1920.

Personal.—Dr. Walter H. McKenzie, Enid, has been appointed superintendent of health and United States Medical Examiner for Garfield County.——Dr. George M. Clifton, Norman, has been appointed superintendent of health for Cleveland County.——Dr. John P. Sudderth, Bartlesville, has been reappointed health officer of Nowata County.——Dr. Eugene O. Barker has been appointed city physician of Guthrie.——Floyd J. Bolend, Lieut.-Col., M. C., U. S. Army, Oklahoma City, commanding officer of the One Hundred and Eleventh Sanitary Train of the Thirty-Sixth Division, has been appointed chief surgeon of the American Forces in Italy.

PENNSYLVANIA

Optometry Bill Favored.—Representative Duncan Sinclair of Fayette County was directed by the committee on health and sanitation to report favorably to the house his bill amending the act of March 30, 1917, so as to require a majority of the state optometry board of seven members to be physicians, licensed under the laws of the state and qualified to practice medicine and surgery and that the other members of the board shall be optometrists.

Personals.—Dr. Joseph T. Rothrock, West Chester, was 80 years of age April 9. The American Forestry Association has announced that eighty memorial trees will be planted in honor of Dr. Rothrock, the "father of forestry" in Pennsylvania.——Dr. Henry A. Hutchison, Dixmont, having completed forty years of continuous service in the Dixmont Hospital for the Insane, thirty-five years as its superintendent, tendered the employees and patients a reception and ball at the institution, April 15.

Harrisburg—Proposed Model City for Health.—Members of the Civic Club, Rotary Club, Chamber of Commerce and other organizations attended a preliminary mass meeting, April 14, in the hall of the house of representatives, Harrisburg, at which was outlined State Health Commissioner Martin's plan to make Harrisburg a model city from the standpoint of public health and sanitation, as an example to the other cities of Pennsylvania, concerning the measures the state health department would have them take. Mayor Keister promised the city's hearty cooperation in the plan, as has Dr. John M. J. Raunick, local health officer.

Philadelphia

Dedicate Negro Hospital.—Buildings of the Protestant Episcopal Divinity School on Woodland Avenue, occupying the entire block between Fiftieth and Fifty-First Street, recently purchased by the Mercy Hospital and School for Nurses, was dedicated, May 25. This is the largest hospital in the United States owned and controlled solely by negroes.

Personal.—Dr. Alexander Sterling, Philadelphia, has been appointed assistant physician pro tem, in the department of medicine of the Jewish Hospital, in the service of Dr. S. Solis Cohen.——Dr. Alexander C. Abbott, professor of hygiene at the University of Pennsylvania and in charge of sanitary supervision for the Second Army, A. E. F., has been promoted to colonel.——Dr. Joshua E. Sweet, Philadelpia, on duty with Base Hospital No. 10, has been promoted from major to lieutenant-colonel.——Provost Edgar Fahs Smith of the University of Pennsylvania celebrated his sixty-third birthday, May 23. A loving cup was presented to him by the students. Provost Smith has been professor for the last thirty years at the university and a provost for eight years.

TENNESSEE

Home for Feebleminded.—The house of representatives has passed on final reading a bill giving the state control of its feebleminded, and providing for the establishment of a home for those who may be declared mentally deficient.

State Board Meeting.—The State Board of Preliminary Medical Examiners will hold its annual meeting in Nashville, June 12, and on the two succeeding days the state board of medical examinations will be held. All who desire to take the state board examinations should appear before the board of preliminary examiners, June 12, and obtain the necessary certificate from this board.

Personal.—Edward C. Ellett, Lieut.-Col., M. C., U. S. Army, Memphis, who was commanding officer of Base Hospital No. 115, returned, May 12.——Dr. A. G. Buckner, formerly adjutant-general of Tennessee, has been elected director of dental hygiene by the state board of health.——Dr. Clarence B. A. Turner, Newbern, has been appointed a member of the state board of health, succeeding Dr. Vincent A. Biggs, Martin.——Dr. John Overton, Nashville, has been appointed prison physician.

TEXAS

Health Bureaus Organize.—The state board of health announces the organization of a bureau of child hygiene, with Dr. Oscar Davis, Anderson, as director, a bureau of communicable diseases with Dr. Horace C. Hall, Laredo, as director, and a bureau of public health education and sanitation and preventive medicine, the director of which will be announced later.

Women's Auxiliary Organized.—At the meeting of the State Medical Association of Texas, at Waco, May 14, the Women's Auxiliary to the State Medical Association of Texas was organized, with Mrs. E. H. Carey, Dallas, president. The object of the organization is to extend the aims of the medical profession through the wives of physicians to the various women's organizations which look toward advancement of health and education, to assist in entertaining in state, district and county medical society meetings, and to promote acquaintance between doctors' families.

Personal.—Dr. Henry E. Luehrs, Mathis, is about to leave for South America, where he will have charge of a large hospital.——Dr. Lane B. Kline, who recently secured his discharge from the Medical Corps, U. S. Army, has been appointed health officer of Houston.——Dr. Thomas A. King, Vernon, has been appointed a member of the state board of medical examiners, succeeding Dr. Dabney Berrey, San Antonio.——Dr. A. J. Cook, Laredo, who recently was discharged from the medical corps of the Army, has been secured as physician and surgeon for the Anaconda Copper Company at Portrellos, Chile.

State Association Meeting.—The fifty-third annual meeting of the State Medical Association of Texas was held in Waco, May 13-15, and the following officers were elected: president, Dr. Robert W. Knox, Houston; president-elect, Dr. Thomas T. Jackson, San Antonio; vice presidents: Drs. Martin E. Taber, Dallas; George H. Lee, Galveston, and William L. Crosthwait, Waco; secretary, Dr. Holman Taylor, Fort Worth (reelected); treasurer, Dr. Wilmer L. Allison, Fort Worth (reelected); trustees: Drs. Charles M. Alexander, Coleman; John S. Turner, Dallas; Charles E. Cantrell; Greenville; John T. Moore, Houston (chairman), and William R. Thompson, Fort Worth (secretary).

WEST VIRGINIA

New State Officers.—At the annual meeting of the West Virginia State Medical Association held in Clarkesburg, May 20 to 22, under the presidency of Dr. Robert J. Reed, Wheeling, the following officers were elected: President, Dr. Henry R. Johnson, Fairmont; vice presidents, Drs. Benjamin F. Shuttleworth, Clarksburg; Walter E. Vest, Huntington; Joseph L. Miller, Thomas; secretary, Dr. J. Howard Anderson, Marytown (reelected); Dr. Hugh G. Nicholsen, Charleston (reelected). Parkerburg was selected as the place of meeting for 1920.

WISCONSIN

Hospital Addition.—The demand for admission to the new Whitehall Community Hospital which was opened last fall has been so great that at the last meeting of the board of directors it was voted to build an addition to accommodate twelve patients. A nurses training school is operated in connection with the institution.

Conference on City Hospital.—The Free Conference of Milwaukee Hospitals, an organization formed for cooperation between medical institutions of the city, held its first meeting, April 20, under the chairmanship of Dr. George C. Ruhland, health commissioner. The council will act only in an advisory capacity, exercising no jurisdiction over the hospitals.

Personal.—Dr. John L. Callahan has been elected president of the board of health of LaCrosse, succeeding Dr. Jacob M. Furstman, who was made head of the department of health of Bloomington, Ill.——Dr. George W. Harrison, Ashland, just returned from overseas, has been elected county physician of Ashland County.——Gustavus I. Hogue, Major, M. C., U. S. Army, Milwaukee, has been promoted to Lieut.-Col., Medical Corps and placed in charge of the Army Eye, Ear, Nose and Throat Hospital in Paris.——Dr. Bertha V. Thomson has been appointed health commissioner of Oshkosh.——Dr. Emil E. Tanner, Milwaukee, has started for Vladivostok, where he will be on duty with the American Red Cross.

CANADA

Personal.—Dr. Archibald P. Knight, for twenty-seven years professor of physiology in Queens University, Kingston, Ont., announces his intention to resign, but will retain his position until his successor has been appointed.

Addition to Endowment Fund.—Queens University, Kingston, Ont., reports that an additional endowment fund of $1,000,000 has been received for the general purposes of the university. With the income of this fund it is proposed to secure several more full-time professors and to develop the departments of physiology and bacteriology and public health. A fund of $200,000 is also available to be expended in the reconstruction of the hospital.

Illegal Practitioner Punished.—In the case of M. H. Thuna, Montreal, who advertised himself as "Dr. Thuna, Specialist. Balsam Medicine for all Diseases," charged by the registrar of the College of Physicians and Surgeons of the province of Quebec with having violated the law regarding the practice of medicine, the accused was found guilty and sentenced to pay a fine of $50, and in default of such payment to be imprisoned for sixty days, in the common prison. The same judgment was rendered on three counts.

LATIN AMERICA

Deaths Abroad.—Dr. H. G. Pinero, professor of physiology in the School of Medicine in the University of Buenos Aires, died recently at Mar del Plata.

The Influenza in Venezuela.—At a recent meeting of the National Academy of Medicine of Caracas, mention was made of the fact that a new wave of influenza seemed imminent, as a number of physicians had already a number of cases of the disease, some of whom had it during the last outbreak.

Pasteur Institute in Nicaragua.—The government of Nicaragua has requested the Mexican government to send a person to establish a Pasteur institute at Managua. The Mexican government has intrusted this task to Dr. G. Leal, who will soon depart for Managua with the necessary personnel and equipment.

GENERAL

Electro-Therapists Meet.—At the annual meeting of the Western Electro-Therapeutical Association, held in Kansas City the second week in May, the following officers were elected: president, Dr. Burton B. Grover, Colorado Springs; vice presidents, Drs. Walter P. Grimes, Kansas City, and Theodore F. Clark, Eldorado, Kan.; secretary, Dr. Charles Wood Fassett, Kansas City, Mo.; treasurer, Dr. Charles Keown, Independence, Mo., and registrar, Dr. Enos A. Nelson, Phillipsburg, Kan.

Venereal Manual Free to Physicians.—The U. S. Public Health Service announces that all physicians agreeing to cooperate with that service and their state board of health in the venereal disease program which has just been agreed on, will be furnished either by the public health service or the state board of health with a copy of the *Manual for the Treatment of Venereal Diseases*, published by the American Medical Association, first issued for the use of the medical officers of the Army and which has now been revised for civilian use with a new chapter on gonorrhea in women.

Pharmacopeial Convention.—Dr. Harvey W. Wiley, Washington, D. C., president of the United States Pharmacopeial Convention, announces the tenth decennial convention, which will meet in Washington, D. C., on the second Tuesday of May, 1920, at 10 a. m., at a hall to be designated hereafter. He asks that all competent and designated bodies and authorities name and issue credentials to the affixed number of delegates to the convention. The appointed delegates are requested promptly to forward their credentials to Dr. Noble P. Barnes, the Arlington Hotel, Washington, D. C., assistant secretary of the convention, who will file them for consideration of the committee on credentials, which will be appointed by the president, not later than March 1, 1920, in accordance with the by-laws. The membership of the convention is made up of three delegates from each of the following: incorporated medical colleges, medical schools connected with incorported colleges and universities; incorporated colleges of pharmacy, and pharmaceutical schools connected with incorporated colleges and universities; incorporated state medical associations; incorporated state pharmaceutical associations; the American Medical Association, and the American Chemical Society. Delegates are appointed, also, by the Surgeon-Generals of the United States Army, Navy and Public Health Service, the Secretary of Agriculture, and the Secretary of Commerce and Labor, the Association of Official Agricultural Chemists, the Association of State and National Food and Dairy Departments, the National Wholesale Druggists' Association, the National Dental Association and by organizations which were admitted to a representation in the convention of 1900.

New York Committee Announces Entertainments for Foreign Guests to the American Medical Association's Annual Session.—The New York City Committee on Reception and Entertainment of Delegates to the American Medical Association has announced the following tentative program for guests from foreign countries to take place on Monday, June 2. The delegates and other foreign physicians will leave the Hotel Waldorf-Astoria for the City Hall by automobile at 11 in the morning. At noon they will be received by the mayor of New York City, the commissioner of health, the commissioner of charities, the president of the board of aldermen, the borough presidents, the deans of the New York medical schools. An address of welcome will be made by the mayor. An opportunity will be afforded to inspect the municipal buildings. At 11:45 the committee will leave the city hall for the Battery where at 1 p. m. it will board the department of charities' steamship *Corrections*. A luncheon will be given to the foreign delegates while on the boat en route up the East River to Willard-Parker Hospital where the boat is scheduled to arrive at 2 o'clock. After an inspection of the laboratories at that hospital, the party will reembark at 2:30 to arrive at Bellevue Hospital at 3 o'clock. After inspection of this hospital, the party will again reembark at 3:30 o'clock, and under the direction of Commissioner Bird S. Coler will visit the Blackwell's Island institutions. They will leave Blackwell's Island at 4:30 o'clock for Randall's Island and the North Brother's Island institutions to visit Riverside Hospital and the health department hospital for drug addicts. Commissioner Royal S. Copeland will be in charge at this point. Physicians visiting New York will be welcome to join this group in inspecting these various institutions, and to attend other events which may be arranged in so far as it is possible to accommodate them after provision is made for the foreign physicians.

Bequests and Donations.—The following bequests and donations have recently been announced:

Eau Claire Hospitals, to be administered by the Visiting Nurse Association, a donation to endow a bed for a year.

Oakville, Tenn., Memphis Sanatorium, a bequest of $1,700 by the will of Frank Trimble.

Brockton (Mass.) Hospital, $5,000 by the will of Elden B. Keith, Brockton.

Lawrence (Mass.) General Hospital, $50,000 by the will of Charles H. Tenney, New York City.

FOREIGN

Personal.—Dr. Albert Calmette, former director of the Pasteur Institute at Lille and now subdirector of the Pasteur Institute in Paris, has been elected an active member of the section on public hygiene and legal medicine in the Paris Academy of Medicine.

Organization of Owners of Private Clinics in Denmark.—The *Ugeskrift for Læger* states that the physicians who have founded private clinics at Copenhagen and in the vicinity have organized and are inviting others throughout the country to join with them for mutual advantage, registering the capacity of the private clinic, the number of beds, and of trained nurses and other attendants and other data.

Prizes Offered by the Spanish Academy of Medicine.—The Real Academia Nacional de Medicina offers a prize for the best work on ferments and antiferments for medicinal use; on the present conception of neurasthenia; on the medical geography and topography of some region in the Asturias, or on an epidemic observed by the writer. The Rubio prize will be awarded for the best medical work published by a Spanish physician in the preceding two years, or the most useful medical invention or remedy.

Medical Congress in Spain.—The first Spanish National Congress of Medicine was held, April 20-25, at Madrid. The king and the minister of education were present at the opening session. Among distinguished foreigners in attendance who delivered lectures were Mme. Curie, the famous French physicist and discoverer of radium, Dr. Vidal of Paris, Dr. Da Fano of Italy and Dr. Wright of England. In connection with the congress was held an exhibition on medicine and hygiene. It is the intention to hold hereafter similar meetings periodically at different places in Spain.

New Hospital Opens.—The new general hospital of the American Church Mission in Wuchang, China, was formally opened, Dec. 14, 1918. The building is three stories in height, is of reenforced concrete and brick structure, is piped for steam heat, hot and cold water, has sanitary drainage, is lighted by electricity, and can accommodate 200 patients. The total cost of land and buildings was more than $100,000. The women's department, known as the Elizabeth Bunn Memorial Hospital, is under the care of Dr. Mary L. James, as superintendent, and the men's department, known as St. Peter's Hospital, is under the superintendency of Dr. C. McA. Wassell.

Northern League Against Tuberculosis.—Representatives of the organizations that have been formed in Denmark, Finland and Norway to combat tuberculosis met at Stockholm in March, on the invitation of the Swedish organization of the same nature. The purpose was to form a general Nordisk Forening mod Tuberkulose, to cooperate all means to stamp out tuberculosis in these northern lands, both the social service side as well as the medical side. An invitation was also sent to the Iceland Medical Society asking for their cooperation. Conferences on tuberculosis are planned. The first one is scheduled to be held at Stockholm in the summer of 1920.

Antivenereal Campaign in Spain.—By a royal decree there has been organized recently in Spain a permanent board to control venereal diseases which will have as its object the study of all measures proposed by the Spanish Antivenereal League, and reporting to the government in regard to the necessary means to combat these diseases. The first meeting of the new board was held in Madrid, April 1. According to the statement made by the director general of public health, Dr. Martín Salazar, it is the intention to follow generally the plan adopted in England, and create institutions for the prompt diagnosis and treatment of these diseases. The personnel of the board includes not only of some of the most prominent physicians of Spain but also of persons representing all social classes.

PARIS LETTER

Paris, May 1, 1919.

Smallpox Vaccination in Paris Factories Manufacturing War Material

In accordance with a decision of the undersecretary of state for the army medical corps the military personnel employed in government factories or engaged in work in connection with the national defense has been revaccinated against smallpox, the work having been assigned to the Paris headquarters of the army medical corps. Drs. E. Marchoux and Klotz reported at a recent meeting of the Académie de médecine the results obtained by this measure. This work was carried out between Jan. 17, 1917, and Dec. 31, 1918, in 4,000 factories distributed throughout the Paris military district. During this period 306,587 vaccinations were made with 124,168 "takes," more than 50 per cent. of which were successful. Because of the danger from infection on account of the contaminating nature of the work done by these persons, who worked with bared arms, only three light punctures were made with the point of the stylet used for this purpose.

Nervous and Mental Disturbances Following Influenza

Dr. Henri Claude reported to the Académie de médecine that he had seen some uncommon but benign nervous disturbances and frequent and serious mental disturbances during the convalescence from and as a result of influenza. The nervous disturbances consisted of various neuralgias, in keeping with the alterations in the nerves or their roots, and of asthenic symptoms in connection with myalgias. In one instance Claude observed a flaccid paralysis with sloughing and the necropsy showed hemorrhages into the gray matter of the cord, the result of considerable dilatation of the small vessels without any apparent inflammatory reaction. The mental disturbances which were noted in seven young women and one boy, aged 13, sometimes took on the form of acute delirium with agitation, violence, fear and erotic excitation, and, at other times, was of a depressive nature. In two cases ideas of persecution followed erotic excitation or a display of negativism. A cure resulted in four cases; three took a very serious turn; two of these terminated in death, and the third patient is recovering from a condition of manic excitement. Necropsy in the fatal cases demonstrated congestive lesions with small meningeal hemorrhages and especially in islands of edema in the cortical substance surrounding greatly dilated small vessels. Nowhere was there any evidence of inflammatory reaction, but the tissue cells were altered in these zones of vasodilatation and edema.

Congress on Social Hygiene

The end of this congress was marked by the adoption of certain resolutions which were the outcome of discussions. The section on school hygiene went on record as favoring the compulsory use of shower baths by schoolchildren; the section on hygienic housing interested itself in the use of new materials in the reconstruction of the regions devastated by the war; the section on sanitary prophylaxis endorsed the establishment of an interallied institute of social hygiene and of dispensaries to combat the disease, and to endow laboratories of bacteriology. It was also urged that shell holes be filled up to prevent the development of malaria; that all engineering work undertaken to supply the army with good drinking water be turned over to the respective communities; that a plan for new schools be submitted to a competent commission consisting of educators and physicians, and that all public carriers shall be required to comply with hygienic rules, such as frequent disinfection, prohibition of spitting, and segregation of smokers.

American Physician Decorated with Legion of Honor

Dr. Alexander Bruno, assistant director of the Rockefeller Tuberculosis Commission in France, has received the decoration of a chevalier of the Legion of Honor in recognition of the care and attention given by this American surgeon since 1916 to the French wounded in the hospitals and of his most valuable cooperation in the organization of the campaign against tuberculosis in France.

French Physicians Honored

Dr. Lejars, professor of external pathology on the Paris medical faculty, and consulting surgeon of the Tenth Army Corps, has received a citation, in the order of the day, for his wise counsel and unselfish devotion to duty.

Dr. H. Somen, médecin aide-major of the first class, has received the decoration of a chevalier of the Legion of Honor for his devotion to duty, energy and bravery. He was wounded three times and has received six citations.

LONDON LETTER

London, May 8, 1919.

A Postgraduate Medical Association

At the Royal Society of Medicine a meeting has been held to discuss the formation of a postgraduate medical association. The basis of the discussion was the scheme described in a previous letter to The Journal. Sir William Osler, who presided, said that there were three possibilities: to extend existing postgraduate schools; to establish separate colleges; or to unite the medical schools, postgraduate colleges and special hospitals in an association which would consolidate all the teaching interests. The last had been chosen as the most hopeful. These various schools and hospitals had consented to arrange special classes and to give facilities for research work and general study. Arrangements, it was hoped, would be made for utilizing the enormous material in the fever hospitals and Poor Law infirmaries, and to give special students an opportunity to study problems relating to public health and preventive medicine. In connection with the representative council, to be set up there would be a permanent secretarial staff, whose duties would be to keep in touch with every medical school in the United States, the dominions, India and Egypt, so that at least every quarter there would appear on the bulletin board of these schools abroad information about postgraduate work in the United Kingdom; also to receive students on arrival in London, and to provide weekly information as to postgraduate facilities. The secretary's office, in fact, would combine the functions of a clearing house and of a university registry. Branch offices could be established at the provincial schools, and it was to be hoped that there would be cooperation with a similar organization in Scotland and Ireland. There would be interchange of information with the Paris Postgraduate Committee; and British students wishing to visit the United States or the dominions for graduate work could find in the central bureau up-to-date information. Another point of importance was the organization in each county center of a yearly postgraduate course of ten days or two weeks, free, or at a very small cost, to all physicians of the neighborhood. Such classes might be held at the county hospitals, and the central organization could be of great help in furnishing special teachers.

Prof. G. E. MacLean (director of the American Universities' Union) pledged the cooperation of that body. When America came into the war 153 of the leading universities and colleges in the United States organized that union to look after the college men in the American Expeditionary Forces. The headquarters of the union were in Paris, and there was one branch in London, and one in Rome. Now the war was over it was hoped to retain the league of universities as an "anchor to the windward" for the League of Nations. Its aim was to bring about interchange of professors and students, and to serve as a clearing house of information, including the giving of particulars to British students as to opportunities for study in the United States.

The following resolution was carried unanimously: "That each London undergraduate medical school be invited to appoint two representatives to serve on the council of the association, and that all other participating institutions be invited to appoint one representative. That the board of education, the medical research committee, the dominions of Canada, Australia, New Zealand, and South Africa, and the United States be invited to appoint one representative each. That the council shall have power to co-opt on the council of the association not more than five distinguished laymen interested in medical education.

The Prevention of Anthrax

A bill has been read a second time in the House of Commons to control the importation of goods infected, or likely to be infected, with anthrax and to provide for their disinfection. In spite of all precautions there has been a steady increase in the number of cases of anthrax in this country. Between 1911 and 1915 there were 164 cases, and between 1915 and 1918, three years only, there were 198. The proportion of fatal cases is approximately 25 per cent. Internal anthrax is almost universally fatal. The bill contains two main provisions. It gives power to prohibit the importation of goods infected or likely to be infected, either absolutely or except at certain specified ports, and it empowers the secretary of state to provide and maintain the necessary works for the disinfection of goods, and to make rules for the payment of fees by the importers of such goods. The cost for setting up the first station for this work was estimated on a prewar basis at $90,000.

Deaths

Henry Davidson Fry ⊕ Washington, D. C.; University of Maryland, Baltimore, 1876; aged 66; professor of obstetrics and clinical professor of gynecology in the Georgetown University, Washington from 1895 to 1917, and since that time emeritus professor of obstetrics; professor of obstetrics in the Washington Post-Graduate Medical School; gynecologist to Garfield Memorial Hospital, and obstetrician to the Columbia Lying-In and Georgtown University hospitals; vice president of the American Gynecological Society in 1904; died at his home, May 12.

Albert Anderson ⊕ Estherville, Iowa; State University of Iowa, Iowa City, 1890; aged 57; also a pharmacist; division surgeon for Burlington, Cedar Rapids and Northern Railway from 1896 to 1902 and since 1902 local surgeon for the Rock Island system; founder of the Anderson Hospital, Estherville; for four years a member of the city council and for several terms a member and president of the board of education; died in the Anderson Hospital, Estherville, May 12, from cerebral hemorrhage.

Warren Fielding Scott ⊕ Lieut., M. C., U. S. Army, Palulah, La.; Tulane University, New Orleans, 1912; aged 30; who served for nine months with the British forces in Flanders and later with the American Expeditionary Forces in Base Hospital No. 24, and was discharged from the service, April 28, at Camp Merritt, N. J.; died in Vicksburg, Miss., May 12, from spinal meningitis.

William H. Bennett ⊕ Atlantic City, N. J.; University of Pennsylvania, Philadelphia, 1869; aged 75; formerly a practitioner of Philadelphia; for many years president of the board of St. Christopher's Hospital and for forty-seven years president and physician in charge of the Children's Sea Side Home, Atlantic City; died at his home, May 14, from cerebral hemorrhage.

Theophilus Caliway Robinson, Long Beach, Calif.; Hahnemann Medical College of the Pacific, San Francisco, 1902; aged 51; who served as a captain, Medical Corps, U. S. Army, at Fort Riley, Kan., and was operated on there for tumor of the bladder, and was honorably discharged from the service, Nov. 15, 1918; died at his home, May 2.

Robert Leach, Columbus, Ohio; Ohio Medical University, Columbus, 1897; aged 45; a specialist in surgery; formerly local surgeon of the Baltimore and Ohio, and Baltimore and Ohio Southwestern railways at Mount Sterling, Ohio; died at his home, May 12, from myocarditis following articular rheumatism.

David Gamble Murrell, New Orleans; Hospital College of Medicine, Louisville, Ky., 1878; aged 70; a Confederate veteran; for several years professor of anatomy in his alma mater, and later a practitioner of Paducah, Ky., where he organized the Railroad Hospital; died at his home, May 17.

Charles H. Raffety, Portland, Ore.; Willamette University, Salem, Ore., 1869; aged 80; also a pharmacist; one of the first mayors of East Portland; for eighteen years a member of the Portland water board; died at his home, May 10, from cerebral hemorrhage.

Thomas Harold Orser ⊕ Capt., M. C., U. S. Army, Cold Brook, N. Y.; Queen's University, Kingston, Ont., 1902; aged 45; visiting physician to the Harlem Dispensary; assistant clinician to the New York University Dispensary; died at his home, April 20.

Junius A. Woolfolk, Thruston, Ky.; University of Louisville, Ky., 1877; aged 62; a member of the Kentucky State Medical Association; died at his home, May 13, from injuries sustained when an automobile collided with a buggy which he was driving.

Joseph Webster Heath, Wakefield, Mass.; Bowdoin Medical School, Brunswick and Portland, Me., 1877; aged 65; past president of the Middlesex East District Medical Society; died in his office, May 15, from cerebral hemorrhage.

Foster Sudler, Sudlersville, Md.; University of Pennsylvania, Philadelphia, 1896; aged 49; vice president of the Sudlersville Bank; who had been a sufferer from tuberculosis for five years; died from that disease at his home, May 8.

⊕ Indicates "Fellow" of the American Medical Association.

narrow study of one or more exciting causes into the nervous power that makes their operation possible, and, by viewing it from every angle and from a higher vantage ground, let us hope to hasten the coming of the day when the whole subject shall be lifted out of the dust of controversy and out of the darkness of hypothesis into the light of imperishable fact.

John N. Mackenzie, Baltimore.

THE ADMINISTRATION OF ARSPHENAMIN

To the Editor:—In your issue of May 10 you publish a letter from the director of the Hygienic Laboratory, U. S. Public Health Service, in which he declares it as a requisite to safe administration of arsphenamin that 0.1 gm. of the drug should be dissolved in at least 30 c.c. of fluid and that each injection of 0.3 gm. of the drug should require at least six minutes.

While I recognize that it is a wise policy to be overcareful in the administration of such a powerful drug and to err, if at all, on the safe side, I must take issue with the concluding remarks: "any physician who fails to observe these precautions should be considered as directly responsible for serious results that follow the improper use of the drug." As a matter of fact, I can state that in the many thousand injections which have been given in my service at Mount Sinai Hospital, it has been the standard rule to dissolve each 0.1 gm. in 20 c.c. of freshly distilled water, and to inject it, not with undue haste, but only in exceptional cases where small veins require the use of small needles, as slowly as Dr. McCoy suggests. The average injection takes about half the time defined by him as the minimum.

It is not in the spirit of controversy but with the aim of protecting the medical profession that I ask you to publish this letter, for I realize that if the occurrence of unavoidable reactions, rare as they are, should lead to a suit for malpractice, a well meant but too apodictical statement from such an authoritative source might be detrimental to a member of the profession.

H. Goldenberg, M.D., New York.

REPRINTS ON DISORDERS OF THE BLOOD

To the Editor:—I am setting out to make a collection of reprints and cuttings from the medical press of papers dealing with the clinical and experimental aspects of disorders of the blood. I have already about 2,000. These are indexed and filed and will, I hope, prove of permanent value.

American literature is not so well represented as I could desire. I have most of the papers on Gaucher's splenomegaly and excerpts from your own pages for the last few years, but much is still lacking. Would you be so good as to print this letter and allow me to ask those interested in the subject to send me any reprints they have.

Accounts of disease chacterized by abnormal shapes of the red cells and by abnormal phagocytosis are practically confined to American literature; there also one looks for much of the work on the spleen and nearly all that on hemolymph glands; purpura is much more fully dealt with than in English literature, and, generally speaking, we have little to compare with your experimental work.

It would be impossible for me to write to each author individually or to keep track of every paper published. Nor can I subscribe to all the journals in which this work is found.

If any reprints of my own are of sufficient interest, I shall of course be delighted to exchange them. Any reprints sent will be acknowledged at once.

I thank you in advance for your courtesy.

Gordon Ward, M.D.,
The Vine, Sevenoaks, Kent, England.

A Foresight.—I hope to live to see the time when the increased efficiency in the public health service—federal, state and municipal—will show itself in a greatly reduced death rate. The federal government can give a powerful impulse to this end by creating a model public health service, and making our national capital a model, sanitary city.—President Taft.

Queries and Minor Notes

Anonymous Communications *and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.*

GLUTEN FLOUR FOR DIABETES

To the Editor:—Will you give me the address of a company which makes gluten flours to be used in the treatment of diabetic patients? Do you consider gluten flour reliable in the treatment of diabetes?

C. T. Pankhurst, M.D., North Star, Mich.

Answer.—Gluten flour is not a "treatment" for diabetes in the sense that it has any remedial value. The treatment of diabetes is essentially dietetic and hygienic, drugs playing a minor rôle. An important feature of the dietetic treatment is the restriction of the carbohydrate intake. As the commonest of the carbohydrate-containing foods is bread, the problem of substituting for ordinary bread a product somewhat similar in character, but without so high a starch content, becomes important. Gluten flours have been developed for this purpose. They are essentially wheat flours from which a large proportion of the starch has been removed, leaving a proportionate excess of the protein element (gluten). It thus becomes obvious that the important element in gluten flours is not the presence of larger amounts of protein, but the comparative absence of starch. There are many so-called gluten flours on the market which are extremely dangerous for use in diabetes because of the large proportion of starch they contain. A safe gluten flour is marketed by Herman Barker, Sommerville, Mass. This has been accepted by the Council on Pharmacy and Chemistry for inclusion in New and Nonofficial Remedies. The Barker product comes in three grades: Grade A contains 4 per cent. carbohydrate; Grade B, 7 per cent.; Grade C, 12 per cent. Certain flours for the use of diabetics in making breads, muffins, etc., that are low in carbohydrate content have also been admitted to N. N. R. These, however, do not have wheat flour as their base, and are therefore not gluten flours, the protein element being derived from the soy bean in one case and from milk casein in another.

ABSORPTION OF WATER FROM THE STOMACH

To the Editor:—I have been taught that water is not absorbed from the stomach. Dr. Casares (The Journal, May 3, 1919, p. 1336) speaks repeatedly to the contrary. Both cannot be right. Is there anything new concerning this question, pro or con?

Edgar A. Hall, M.D., Coal City, Ill.

Answer.—The article referred to is on the "Treatment of Malaria" by J. M. Casares y Bescanza, published in *Plus Ultra*, Madrid, p. 186, and abstracted in The Journal of May 3. According to most physiologic textbooks, water is not absorbed from the stomach. Fluids pass through the stomach rapidly and are absorbed from the intestine. For years physiologic laboratories have given to medical classes a practical demonstration of this fact. A cat is lightly anesthetized, and 50 c.c. of distilled water heated to 37 C. is introduced into the empty stomach, the cardiac orifice of the stomach having previously been ligated off and a ligature placed about the pylorus. A similar amount of water is introduced into the small intestine, both ends of which are closed by ligatures. Care is taken *not* to interfere with the blood supply to the stomach or intestine. The animal is allowed to recover from the anesthetic and after from three to four hours is again anesthetized. The gastric and intestinal contents are measured, and the stomach is found to contain, on the average, about 47 c.c. of the water introduced—sometimes more, sometimes less; the intestines are invariably empty. Hence, the stomach absorbs practically none of the water, while the intestines absorb all. The slight apparent absorption from the stomach—3 c.c. in three hours—may be accounted for by the adherence of some of the water to the mucous membrane, and this water cannot be recovered. Experiments have shown that absorption of pure distilled water from the stomach is practically nil.

Saline solutions, however, are absorbed from the stomach in appreciable degree when in comparatively high concentration. Howell writes of sodium iodid solution that "Not until its solutions reach a concentration of 3 per cent. or more does its absorption become important." Experiments have shown that solutions of strychnin are absorbed from a Pawlow's stomach of a dog, precluding the possibility that the solutions were passed into the intestine before absorption. Sugars are likewise absorbed, particularly in concentrated form, according to a number of authors. Aminoacids are absorbed from the stomach; Folin found that urea is also absorbed. The question of the absorption of fat by the stomach has been affirmed and denied.

Dr. Ivy, working in the laboratory of the University of Chicago, found no evidence in his work or in the literature that distilled water as such is absorbed by the stomach. Regarding its rate of evacuation, Dr. Ivy has written an article on "Studies on Water Drinking" in the *American Journal of Physiology*, July, 1918 (volume 46, No. 4, p. 429). As judged from his own series of experiments on this point, he concludes that "the emptying of water from the normal stomach varies, conservatively, from 400 c.c. to 100 c.c. in fifteen minutes." It is a fact, as verified by Dr. Ivy and recorded by him, that "the greater the amount of fluid, the more rapidly does it leave the stomach."

So far as known, no one has worked with solutions of quinin. It is possible that they are absorbed slightly, just as are other diluted solutions. It is more probable, however, that they are passed into the intestine and that the real absorption occurs in that viscus.

LICENSURE OF DISCHARGED MEDICAL OFFICERS

To the Editor:—It has been rumored that some state licensing boards will register discharged medical officers of the United States Army without further examination. A statement of the facts will be appreciated.

C. W. A.

Answer.—The laws in seven states—Alabama, California, Colorado, Illinois, North Dakota, Virginia, West Virginia—and in Porto Rico authorize the licensing boards in their discretion to register, without further examination, retired medical officers of the United States Army, Navy and Public Health Service, if, in their opinion, those candidates have undergone a test of their educational qualifications fully equal to that required in the respective states. The secretaries of the several state boards have written that this arrangement does not apply to the civilian physicians who entered the government services during the recent war emergency, since the latter were not required to undergo the severe tests applied to the regular officers of the services named. Attention is called, however, to the liberal provision made by most of these states for registration by reciprocity. —[Full information in regard to reciprocity in all states is contained in a book entitled "Laws and Board Rulings." A copy of this book will be sent to any address on receipt of 50 cents.]

GATHERING INFLUENZA STATISTICS

To the Editor:—In one of the Journals which I have read this year I recall a note regarding a department or bureau of statistics, either in Chicago or Washington, devoted to compilation of data relative to influenza and related respiratory conditions during the epidemic from August, 1918, to May, 1919. Will you kindly inform me where I can get such statistics?

F. S. Minns, M.D., Toronto, Can.

Answer.—A joint committee was created in February, 1919, for the purpose of studying the epidemic and gathering statistics. The members of the committee are: Dr. William H. Davis, Bureau of the Census, Washington, D. C., chairman; Mr. C. S. Sloane, representing the Bureau of the Census; Dr. Wade H. Frost and Mr. Edgar Sydenstricker of the Public Health Service; Col. D. C. Howard, Col. F. F. Russell and Lieut.-Col. A. G. Love, U. S. Army; Lieut.-Com. J. R. Phelps and Surg. Carroll Fox, U. S. Navy.

INTERCOSTAL PAIN FOLLOWING HERPES ZOSTER

To the Editor:—Please tell me what can be done for a severe intercostal pain that has persisted for three years following herpes zoster. The patient states that the pain is as severe now as it was when the attack began.

J. W. W., Chicago.

Answer.—The possibility of spinal tumor, caries or aneurysm should be borne in mind in these cases. The treatment of this intercostal pain, a common sequence of herpes zoster, should be directed in view of the diagnostic findings. The neurotic factor is often present, requiring psychic treatment. Light blistering over the painful points may help. Local warmth and restriction of movement of the ribs by a bandage are often serviceable. Stretching the nerves and resection of the ribs has been done, but not always with success. Sometimes alcohol is injected subcutaneously over the painful points or as close to the nerve trunk as possible.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Alabama: Montgomery, July 8. Chairman, Dr. S. W. Welch, State Capitol, Montgomery.

Arizona: Phoenix, July 1. Sec., Dr. Allen H. Williams, 219 Goodrich Bldg., Phoenix.

California: San Francisco, June 23-26. Sec., Dr. Charles B. Pinkham, 904 Forum Bldg., Sacramento.

Colorado: Denver, July 2. Sec., Dr. David A. Strickler, 612 Empire Bldg., Denver.

Connecticut: New Haven, July 8-9. Sec., Regular Bd., Dr. Charles A. Tuttle, 196 York St., New Haven; Sec., Homeopathic Bd., Dr. Edwin C. M. Hall, 82 Grand Ave., New Haven; Sec., Eclectic Bd., Dr. James E. Hair, 730 State St., Bridgeport.

Delaware: Wilmington, June 17-19. Sec., Dr. H. W. Briggs, 1026 Jackson St., Wilmington.

District of Columbia: Washington, July 8-10. Sec., Dr. E. P. Copeland, The Rockingham, Washington.

Florida: Jacksonville, June 16-17. Sec., Dr. W. M. Rowlett, Citizens Bank Bldg., Tampa.

Florida: Eclectic Board, Jacksonville, June 9-10. Sec., Dr. G. A. Munch, 1306 Franklin St., Tampa.

Georgia: Atlanta and Augusta, June 5-6. Sec., Dr. C. T. Nolan, Marietta.

Illinois: Chicago, June 16-19. Supt. of Registration, Mr. F. C. Dodds, Springfield, Ill.

Iowa: Iowa City, June 12-14. Sec., Dr. Clifford H. Sumner, Capitol Bldg., Des Moines.

Kansas: Topeka, June 17. Sec., Dr. H. A. Dykes, Lebanon.

Kentucky: Louisville, July 1-3. Sec., Dr. J. N. McCormack, Bowling Green.

Louisiana: New Orleans, July 1-3. Sec., Dr. E. W. Mahler, 141 Elk Place, New Orleans.

Maine: Augusta, July 1-2. Sec., Dr. Frank W. Searle, 776 Congress St., Portland.

Maryland: Baltimore, June 18-21. Sec., Dr. J. McP. Scott, Hagerstown.

Massachusetts: Boston, July 8-10. Sec., Dr. Walter P. Bowers, State House, Boston.

Michigan: Ann Arbor, June 10-12. Sec., Dr. B. D. Harison, 504 Washington Arcade, Detroit.

Minnesota: Minneapolis, June 3-6. Sec., Dr. T. S. McDavitt, 741 Lowry Bldg., St. Paul.

Mississippi: Jackson, June 24-25. Sec., Dr. W. S. Leathers, University.

Missouri: St. Louis, June 9-11. Sec., Dr. George H. Jones, State House, Jefferson City.

National Board of Medical Examiners: Philadelphia, June 2-7. Sec., Dr. J. S. Rodman, 1310 Medical Arts Bldg., Philadelphia.

Nebraska: Lincoln, June 30-July 2. Sec., Dr. H. J. Lehnhoff, 514 First National Bank, Lincoln.

New Jersey: Trenton, June 17-18. Sec., Dr. Alex. MacAlister, 438 E. State St., Trenton.

New Mexico: Santa Fe, July 14. Sec., Dr. R. E. McBride, Las Cruces.

New York: Albany, Buffalo, New York and Syracuse, June 24-27, Mr. George M. Wiley, director, Exam. and Inspections Div., State Edu. Bldg., Albany.

North Carolina: Raleigh, June 23. Sec., Dr. H. A. Royster, 423 Fayetteville St., Raleigh.

North Dakota: Grand Forks, July 1-4. Sec., Dr. G. M. Williamson, 860 Belmont Ave., Grand Forks.

Ohio: Columbus, June 3-6. Sec., Dr. H. M. Platter, State House, Columbus

Oklahoma: Oklahoma City, July 8-9. Sec., Dr. J. J. Williams, Weatherford.

Oregon: Portland, July 1-3. Sec., Dr. Frank W. Wood, 559 Morgan Bldg., Portland.

Pennsylvania: Philadelphia and Pittsburgh, July 8-10. Sec., Nathan C. Schaeffer, State Capitol, Harrisburg.

Rhode Island: Providence, July 10-11. Sec., Dr. B. U. Richards, State House, Providence.

South Carolina: Columbia, June 10. Sec., Dr. A. Earle Boozer, 1806 Hampton St., Columbia.

South Dakota: Deadwood, July 8. Sec., Dr. P. B. Jenkins, Waubay.

Tennessee: Knoxville, Memphis and Nashville, June 13-14. Sec., Dr. A. B. De Loach, Exchange Bldg., Memphis.

Texas: Austin, June 24-26. Sec., Dr. M. F. Bettencourt, Mart.

Utah: Salt Lake City, July 7-8. Sec., Dr. G. F. Harding, 407 Templeton Bldg., Salt Lake City.

Vermont: Burlington, June 26-28. Sec., Dr. W. Scott Nay, Underhill.

Virginia: Richmond, June 17-20. Sec., Dr. J. W. Preston, 215 S. Jefferson St., Roanoke.

Washington: Seattle, July 1-3. Sec., Dr. C. N. Suttner, 415 Old National Bank Bldg., Spokane.

West Virginia: Huntington, July 8-10. Sec., Dr. S. L. Jepson, Masonic Bldg., Charleston.

Wisconsin: Milwaukee, June 24-26. Sec., Dr. J. M. Dodd, 220 E. 2nd. St., Ashland.

Wyoming: Cheyenne, June 23-25. Sec., Dr. H. E. McCollum, Laramie.

New Hampshire March Examination

Dr. Charles Duncan, secretary of the New Hampshire State Board of Medical Examiners, reports the written examination held at Concord, March 13-14, 1919. The examination covered 9 subjects and included 80 questions. An average of 75 per cent. was required to pass. Four candidates were examined, all of whom passed. Three candidates were licensed through reciprocity. The following colleges were represented:

College PASSED	Year Grad.	Per Cent.
Boston University	(1918)	78
Harvard University	(1919)	81
Tufts College Medical School	(1919)	82
University of Pennsylvania	(1918)	85

College LICENSED THROUGH RECIPROCITY	Year Grad.	Reciprocity with
Boston University	(1917)	Mass.
University of Vermont	(1883) (1898)	Vermont

District of Columbia April Examination

Dr. Edgar P. Copeland, secretary of the Board of Medical Supervisors of the District of Columbia, reports the oral and written examination held at Washington, April 8-10, 1919. The examination covered 16 subjects and included 80 questions. An average of 75 per cent. was required to pass. Of the 9 candidates examined, 8 passed and 1 failed. One candidate was licensed through reciprocity. The following colleges were represented:

College PASSED	Year Grad.	Per Cent.
Georgetown University	(1916)	85.2
George Washington University	(1911) 84.2; (1918)	92.5
Howard University	(1916)	77.8
Bowdoin Medical School	(1918)	76.6
Johns Hopkins University	(1913) 91.7; (1918)	91.7
McGill University	(1910)	85.7
FAILED		
Chicago Hospital College of Medicine	(1918)	63.6

College LICENSED THROUGH RECIPROCITY	Year Grad.	Reciprocity with
Medical College of Virginia	(1912)	W. Virginia

Oregon January Examination

Dr. Frank W. Wood, secretary of the Oregon State Board of Medical Examiners, reports the written examination held at Portland, Jan. 7, 1919. The examination covered 11 subjects and included 90 questions. An average of 75 per cent. was required to pass. Of the 17 candidates examined, 14, including 2 osteopaths, passed, and 3 failed. The following colleges were represented:

College PASSED	Year Grad.	Per Cent.
Northwestern University	(1907)	80.9
Kansas Medical College	(1897)	79.1
University of Minnesota	(1895)	82.9
John A. Creighton Medical College	(1902)	79.7
Albany Medical College	(1899)	80.1
University of Oregon (1918) 80.1, 83.1, 84.2, 85.4, 88.1, 90.1.		
Jefferson Medical College	(1916)	82.6
FAILED		
Hospital College of Medicine	(1894)	66.2
Missouri Medical College	(1895)	68.3
Gate City Medical College*	(1908)	71

* Official reports state that recognition was withdrawn from this school by the Texas State Board of Medical Examiners in November, 1907; that the dean, Dr. J. W. Decker, was caught selling diplomas in 1911, and was convicted and sentenced to fifteen months' imprisonment.

Rarity of Trachoma in Guatemala.—R. P. Luna states that for twelve years he has been seeking trachoma in his service of ophthalmology at the general hospital in Guatemala, and he has never found a case except imported ones. His communication on the subject, published in the *Juventud Medica* of Guatemala **18**:13, 1918, relates that certain persons deported from North American ports on account of trachoma proved to have merely a simple conjunctivitis which healed readily under ordinary measures. Grayish-whitish scar lines, granulations and pannus are unmistakable when encountered together, but the differential diagnosis in other stages of trachoma is often extremely difficult. Guatemala seems to be one of the favored countries which escape the disease, and where it does not spread when imported, not even to the wife, children or servants. On the other hand, Guatemalans may contract the disease in other lands; the individual and collective immunity seems to be peculiar to the country itself.

Book Notices

A TEXTBOOK OF PATHOLOGY WITH A FINAL SECTION ON POST-MORTEM EXAMINATIONS AND THE METHODS OF PRESERVING AND EXAMINING DISEASED TISSUES. By Francis Delafield, M.D., LL.D., and T. Mitchell Prudden, M.D., LL.D., Emeritus Professor of Pathology, College of Physicians and Surgeons, Columbia University. Eleventh edition. Revised by Francis Carter Wood, M.D., Director of the Pathological Department, St. Luke's Hospital, New York. Cloth. Price, $7.50. Pp. 1354, with 824 illustrations. New York: William Wood & Co., 1919.

Dr. Wood has made a very thorough and careful revision of Delafield and Prudden's well known book, following as closely as possible the plan of previous editions. The many new references to recent literature, especially American, will prove helpful. The illustrations, many of them new, are, almost without exception, highly satisfactory; indeed, only a few, as, for instance, Figure 566, pertaining to tuberculous nephritis, need be replaced by better ones. Figure 462, illustrating gelatinous carcinoma of the stomach, does not seem quite clear enough and should not, as it is now, be referred to as showing, in the strict sense, diffuse infiltrating carcinoma of the stomach. A few minor mistakes have been noted, as, for instance, on page 178—"much experimental data has been brought forward." The rule that the scientific names of bacteria shall be binomial is disregarded in some cases; fusiform bacilli probably merit a little more attention than they have received, and there is no reference to them in the index. No reference is made to recent American articles on hemorrhage into the suprarenals. This book deservedly still holds its place as a standard textbook for students and practitioners.

TUBERCULOSIS OF THE LYMPHATIC SYSTEM. By Walter Bradford Metcalf, M.D., Associate in Clinical Medicine, University of Illinois. Cloth. Price, $2.75. Pp. 216, with illustrations. New York: The Macmillan Company, 1919.

This book is written in a rather fluent style and is devoted largely to a random, and, not infrequently, second-hand review of the literature bearing on the subject of tuberculosis of the lymphatic system. It does not deal with the results of any investigative work on the part of the author except so far as it summarizes his experience in the treatment of lymphatic tuberculosis with tuberculin. The influence an attack of measles may have on the tuberculin reaction is not stated correctly, and no mention is made of the fact that the reaction may be suspended on account of measles. The word toxin is used rather loosely.

In the earlier chapters the capitalization is sometimes rather freaky, quite a few of the names of authors quoted are misspelled, and the references are given in a most haphazard sort of a way. While there are many defects the parts dealing with diagnosis and treatment are creditable and reveal good sense and sound judgment.

DIAGNOSTIC CLINIQUE: EXAMENS ET SYMPTOMES. Par le Dr. Martinet. Paper. Price, 30 francs. Pp. 912, with 783 illustrations. Paris: Masson et Cie, 1919.

From the beginning of the new diagnostic science, most significant of which was Laennec's invention and use of the stethoscope a century ago, the French have contributed their share to the art of making clinical diagnosis more thorough, more accurate and more useful. The plan of Dr. Martinet's book is simple, his aim having been to meet as fully as possible the needs of the average practitioner. He presents in detail the two steps that enter into diagnosis: the collection of signs and symptoms by means of the clinical history and the examination, and the coordination of the data obtained so that the character of the disease may be inferred. The complete diagnosis is for him the sum of four partial diagnoses: clinical or syndromatic, lesional or anatomic, functional or physiologic, and causal or etiologic. The book is divided into three parts. In the first, entitled "Généralités," the author discusses the characteristics of a good diagnosis and the errors that may occur. He also reviews rather succinctly the nosologies in favor at various periods, ending with the etiologic classification proposed in 1905 by Lancereaux and Paulesco. A chapter is devoted to errors in diagnosis and their causes which he apportions among ignorance, deficient examinations and errors of judgment. The second part called "Techniques," is divided into three headings: special; general which includes parasitology and bacteriology; and anthropometry. In the first subdivision the various systems of the body are considered separately. In the third part the methodical organization of data is considered and principles established to assist in medical examinations in ordinary calls, in consultation, and in special consultations. Symptoms are discussed, and grouped into practical and suggestive tables. The book has 783 illustrations, a number of which are in colors, many new and some so well designed that a glance suffices to give an understanding of the technic they represent. The descriptions are written in a clear style and free from all unessential details. An English translation of this unusual book on diagnosis should prove worth while.

Medicolegal

Prosecution for Advertising as a Physician

(State v. Kaatz (Vt.), 104 Atl. R. 873)

The Supreme Court of Vermont finds no error in this case, where the respondent was prosecuted for, and convicted of, advertising and holding himself out to the public as a physician and surgeon without being licensed as required by law. The court says that he demurred to the information, and, on his demurrer being overruled, moved to have the case sent to the supreme court before final trial, which motion was also overruled, to which action he excepted. The case was then tried by jury, and a verdict of guilty was found, and the case came to the supreme court on the exceptions to the overruling of the demurrer and motion. The only ground of demurrer stated in his brief was that the information did not specifically charge him with having "practiced medicine without a license." But the prosecution was not for practicing medicine contrary to law, and it was unnecessary to allege that he practiced medicine without a license, and the information was not subject to demurrer for failure to so allege. As to his exception to the refusal of the trial court to pass the case to the supreme court before final trial, no authorities were cited in his brief supporting this exception, and none, the supreme court thinks, can be found. It was a matter wholly within the discretion of the trial court, and being within the discretion of the trial court, and it not appearing that that discretion had been abused, it was not reviewable by the supreme court, the judgment of which is that there was no error, and that the respondent take nothing by his exceptions; let execution be done.

Loss of Use Considered Equivalent to Loss of Eye

(Smith v. F. & B. Construction Co. et al. (N. Y.), 172 N. Y. Supp. 581)
(Hobertis v. Columbia Shirt Co., Inc., et al. (N. Y.), 173 N. Y. Supp. 606)

The Supreme Court of New York, Appellate Division, Third Department, in the Smith case affirms an award by the state industrial commission of compensation under the workmen's compensation law for the "permanent loss of use of the right eye considered as the equivalent of the loss of such eye," where it appeared that with the use of powerful glasses the claimant had a vision of about one third with that eye, but that in order to obtain it he must close the other eye; that in any event he could have only one eye, and if he used the injured eye he had the vision of but one third of an eye. The court distinguishes the case from one in which by the use of glasses the claimant had the normal vision of the nijured eye, while, without glasses, he had the vision of but one eye, and with the use of glasses had the normal vision of the other eye only; in any event, had the full vision of one eye, and could use either eye at pleasure.

In the Hobertis case, the same court affirms an award of the state industrial commission for the permanent loss of the use of an eye, where the claimant was nearsighted, having not to exceed 50 per cent. vision, and lost the use of an eye, and it was contended that she should be allowed for the loss of half-vision only. The court says that the statute does not provide that the loss of the use of an eye shall be compensated by an award based on the amount of vision which existed previous to the accident, whether it be 50 per cent. or 80 per cent. of vision lost. It awards specific compensation for the loss of an eye. It is matter of common knowledge that very few persons have complete and perfect vision. The claimant was working with defective vision. So far as appeared, her work was entirely satisfactory to her employer, at least so far as the wages she received. The wages received by her must be considered her wage-earning capacity with defective vision. She lost the use of her eye, such as she had, and was entitled to compensation therefor, based on her earning capacity.

No Proof of Registration

(Reum v. State (Tex.), 206 S. W. R. 523)

The Court of Criminal Appeals of Texas reverses a conviction of defendant Reum, and remands the case, because the trial court instructed the jury that in this case it did not devolve on the state to prove that the defendant did not have a license or diploma, with verification of same, and did not have same registered, and the prosecution introduced no proof at all showing or tending to show that the defendant had not registered in the district clerk's office, as required by the statute, her authority to practice medicine. For this error the case must be reversed. But the court did not err in excluding the testimony of the district clerk, offered by the defendant, and the record in his office in the register of physicians and surgeons showing certain entries made in February, 1900, under an old law that was then in force, as the law under which those entries were made has long since been repealed, and the statute under which this prosecution was based prescribed an entirely different record and registration.

Rights Not Lost by Efforts to Save Finger

(Enterprise Fence & Foundry Co. v. Majors (Ind.), 121 N. E. R. 6)

The Appellate Court of Indiana, Division No. 2, says that the injury suffered by plaintiff Majors, while in the employ of the defendant company, consisted of a twist and laceration of the index finger of the right hand. The industrial board found that at the time of the injury the attending surgeon employed by the company at first advised the amputation of the index finger, but the plaintiff remonstrated and insisted that the finger should be saved if possible, and, in response to his objection, the attending physician advised that he had saved fingers as badly injured as that one, and it was agreed to make an effort to save the finger. The finger was treated for about a month or a little more, in an endeavor to save it, but an infection developed which involved practically the whole of the hand, and made necessary the amputation of the index finger, which was amputated at the middle joint. The infection developed because of the delay in amputation. An award was agreed on for the loss of the index finger; but the plaintiff subsequently asked for additional compensation because the second and ring fingers of his right hand were left stiff and permanently injured. This was opposed by the company on the ground that the plaintiff could not recover compensation for a permanent injury to his hand, when the permanent injury was due to his refusal to permit the attending surgeon to perform a surgical operation not of itself dangerous or attended with extraordinary suffering, which, if it had been performed when it was advised, would have prevented infection and saved the permanent impairment complained of. The court agrees that the law seems to be well settled that an injured employee seeking compensation must submit to an operation which will cure him when so advised by his attending physician, when not attended with danger to life or health or extraordinary suffering, and, if as a result of a refusal on his part he suffers a permanent impairment, the employer will not be required to compensate him for the resulting permanent impairment. But the court considers that the plaintiff's insistence that his finger be saved if possible, when taken with the statement made by the surgeon; was not such unreasonable or wilful misconduct as would prejudice the allowance of additional compensation. In other words, the court is satisfied, under all the evidence, that the industrial board was justified in reaching the conclusion that the plaintiff's second and ring fingers had become in part permanently impaired after the agreed award for the loss of the index finger, and it was warranted in granting an additional award for the partial permanent injury to the second and ring fingers, which were left stiff owing to an infection.

MEDICAL SOCIETY OF THE STATE OF NEW YORK

One Hundred and Thirteenth Annual Meeting, held at Syracuse, May 6-8, 1919

(Concluded from page 1567)

Diagnostic Methods in Anemias

Dr. A. H. Sanford, Rochester: Besides the findings of the ordinary blood examinations, and the clinical history, the following methods are helpful in arriving at a diagnosis: (1) analysis of gastric contents by means of the Ewald test meal with subsequent radiographic examination of the stomach; (2) a careful neurologic examination and examination of the eyegrounds; (3) tests for fragility of the erythrocytes; (4) detection of evidences of blood destruction by determinations for urobilin and urobilinogen in the stool, or preferably in the duodenal contents (Schneider's method); (5) serologic tests for syphilis; (6) examination of stools for parasites; (7) inspection of the mouth, especially the tongue, and a thorough examination of the teeth and tonsils. The possibility of chronic sepsis originating here, and of foci of infection in other parts of the body should have general consideration.

Postoperative Shock Hemorrhage and Cardiac Dilatation

Dr. John Osborn Polak, Brooklyn: The preoperative index of a woman's cardiac strength is the pulse pressure. It makes no difference, so far as the operative prognosis is concerned, whether the systolic blood pressure is 105 or 160 mm. so long as the diastolic pressure is not within 30 mm. of the systolic. In other words, provided the metabolism is near the normal, the pulse pressure of the individual is the index of cardiac strength, no matter what her systolic blood pressure may be. The only exception is the very high pulse pressure in aortic regurgitation. The hemoglobin and leukocyte count are the next important factors for preoperative determination, and the blood coagulation time is also of considerable significance. These observations, together with kidney function tests, are made as a preoperative routine. This gives the woman her greatest margin of safety and affords the surgeon a basis for his differential diagnosis in postoperative conditions. There is a constant rise of from five to fifteen points in the hemoglobin readings following anesthesia with ether when such anesthesia occupies more than thirty minutes. Consequently, allowance must be made for this rise in using hemoglobin estimations as a diagnostic sign in internal bleeding. The erythrocyte count is also increased, but its variation from the preoperative count is very slight. In the majority of cases there is a moderate fall in both the systolic and diastolic blood pressure following ether anesthesia. The blood pressure returns to the preoperative reading in from twelve to forty-eight hours. The inhalation of oxygen after the withdrawal of the ether vapor diminishes this fall in blood pressure, but is only transient in its effect. In cases of shock, especially when much blood has been lost during the operation, the fall in blood pressure is greater than after long operation without blood loss, being from 10 to 50 mm. The pulse pressure is a better index of hemorrhage or cardiac failure than is the systolic pressure. There is a constant rise in the leukocyte count in hemorrhage, while the leukocyte count falls in shock.

The Doctor and the Changing Order

Dr. George B. Vincent, President of the Rochefeller Foundation: The medical profession should prepare to adapt itself to the changing social conditions. The doctor faces an entirely new situation from that of ten years ago. New knowledge and new discoveries have accumulated so rapidly that it is impossible for any one man to keep up with them. Specialism is the only solution. The physician is becoming less and less able independently to perform his work efficiently. The cooperative clinic is already being operated successfully. A maternity clinic in Boston is so conducted that the mother receives prenatal care, medical service at the time of the birth of the child and after-care, all for an inclusive fee. There are also the infant welfare, tuberculosis and venereal clinics.

As to health insurance, there is a possibility of developing some plan that will protect the industrial population against pauperism and social dependence and which will preserve its dignity and enable it to maintain its status in the democracy. It will be necessary to learn to conform ourselves to new social ideals in order to perform our function to society and to be a part of the common life.

Research and Clerical Work.—For the most part among us the great prizes go to the man who works up through clerical rather than through expert lines. We must find some way to change this. The path of science must lead to the top, and at the top must still be science. To achieve this ideal, the scientist must show generosity toward colleagues and subordinates, an enthusiastic recognition of their merit and an abnegation of self-aggrandizement, no less than skill in plan and energy in execution. It is essential also that he should develop methods for conserving time and strength by assigning clerical work to clerks instead of becoming a clerk himself, in order that he may keep mind and desk clear for the really important things.—Yandell Henderson: The Physiology of the Aviator, *Science*, May 9, 1919.
